CONTENTS

ELECTRIC HEATING ON A LARGE SCALE.

Electric heating, ideal from so many points of view, has seldom been employed on a large scale, if one except the electric furnace. There are several factors which have combined to prevent this, the two principal ones being the cost of the apparatus itself and the rates charged for electrical energy. It is generally overlooked that while the cost for a single thermal unit in the form of electrical energy may be high, the economy with which this is used brings the total cost much closer to that of an equivalent heating system using fuel. Strictly speaking, of course, it is rather the inefficiency of the fuel-using apparatus which brings the cost of operating them up nearer to that of the electric heater. But there are other factors which at times are even more important than an apparent considerable difference in the actual cost of the heating.

At the recent convention of the American Institute of Electrical Engineers a paper of some interest was read by C. E. Waddell, which describes one of the largest electric-heating systems in this country. This is installed at the Biltmore Estate, Biltmore, N. C., the reasons for its adoption being the cost of anthracite coal and the nuisance involved in its use. These objections led to the introduction of electric heaters for the hot-water system of the house and for performing all the laundry work of the household. The total rating of the installation as it stands is 167 kilowatts, 100 of which is represented by the hot-water heater and sixty-seven by the laundry equipment. The system consumes about 20,000 kilowatt-hours a month, a fairly respectable load.

In the paper Mr. Waddell gave some interesting data respecting the performance of the apparatus installed. The hot-water heater, which is really a small horizontal tubular boiler having electrical heaters inserted in the tubes, was found to give a thermal efficiency of about eighty-five per cent. This seems low, for with complete lagging there should hardly be fifteen per cent loss in radiation. It probably, however, represents fairly well the average all-day efficiency of the heater. The performance of the laundry apparatus is indicated by the records of a number of washes, but seems to vary considerably according to the size of the wash, and a larger number of trials must be noted before one will be able to figure closely on the performance to be expected of such devices. For instance, it was found that on one day sixty-eight pounds of water were expelled for every 100 kilowatt-hours supplied to the electric heater. On another day, for a somewhat smaller wash, 115 pounds of water were expelled for each 100 kilowatt-hours. But while closer figures are desirable from the engineering standpoint, so that the actual requirements of such apparatus may be known, it should be insisted upon that these are not the controlling factors for determining the selection of such devices. What might be called the "all-over economy" of the system is what should be borne in mind. Time and convenience are as valuable as fuel, and generally less available, and it is very easy to see that in an installation of this kind, although the heating engineers might figure out an enormous difference between the costs of producing a given amount of heat by the two methods, this feature may really be of minor importance and the installation of the electric system be a true economy. Indeed, given cheap electrical energy, it might often be found that there would no longer be any need of providing chimneys in summer residences.

PROGRESS IN WIRELESS TELEPHONY.

In an interesting paper by Mr. R. A. Fessenden on "Wireless Telephony," at the annual convention of the American Institute of Electrical Engineers, held at Atlantic City, N. J., this week, an excellent review of the history of this art was given. Certainly one of the most fascinating fields thrown open to the modern investigator has been the study of the principles underlying wireless transmission of signals and the development of apparatus for reducing different scientific possibilities to an art. This art was divided by Mr. Fessenden into two periods, the distinguishing features of the two constituting what is really a radical change in the method of transmission. The first period of wireless signaling may be considered as starting from the discovery of electromagnetic induction; that is to say, the transmission of electrical energy from one body to another without any intervening conductor. No real progress was made in the art, however, until after Hertz's work proved the existence of electric waves. A few years after this the discovery that an imperfect contact was sensitive to such waves made possible their utilization for transmitting signals, and fairly satisfactory methods were developed for this purpose. The distinguishing feature of this development was the use of spark discharges for producing the signals, these giving rise to discontinuous, sharply damped waves.

The second period is marked by the introduction of methods for continuous undamped signals which are much better for the purpose for a number of reasons, among which may be mentioned the greater ease of tuning, the increase in the effectiveness of the transmitting and signaling apparatus when using signals of this type, and the improved conditions under which the apparatus is used; that is to say, there is less strain, and, therefore, the apparatus is easier to construct and less liable to break down.

As a result of this development in wireless telegraphy wireless telephony became possible, for, given a continuous undamped signal, to transmit articulate speech it is only necessary to superimpose upon the signal variations corresponding to ordinary telephone currents. This has been done and Mr. Fessenden, among others, has produced a working wireless telephone system. Such a system of communication will for many purposes be far more satisfactory than a telegraph, since the latter requires the services of an expert operator, while the wireless telephone is as simple to use as the ordinary instrument. With such a gain, naturally some sacrifice must be expected, which in this case is that of range of operation. The harmonics rendering the human voice intelligible have amplitudes of varying length, but sometimes only about one per cent as great as that of the fundamental note. Hence, since the transmission of the voice by wireless waves is produced, not by the fundamental wave itself, but by the variations of this, it would seem that the distance of transmission of the voice would be only one-hundredth of that attainable by the wireless telegraph. Fortunately this severe restriction may be considerably modified by increasing, in the transmitter, the ratio of the harmonics to the fundamental and because the ear seems to be more sensitive to spoken words that to mere clicks. The range of transmission of the telephone, however, is considerably less than that of the telegraph, Mr. Fessenden putting it at about one-tenth or more of the latter, but this distance is modified very greatly by atmospheric conditions.

Regarding the possibilities of wireless telephony, it is evident, as pointed out, that there is not much possibility of replacing the present local manual telephone systems, as it is out of the question for every subscriber to install and maintain his own wireless plant. For long-distance transmission, on the other hand, Mr. Fessenden thinks there is a good opening, an advantage of the system being the absence of interruption due to storms blowing down the transmission lines. The flexibility of the system is thought to be greater, as the "wireless circuits" connecting, say, New York and Chicago, and Boston and Chicago, could be used to connect Boston and New York when the regular Boston and New York "wireless circuit" was in use. The most promising opening at present, however, is in connection with its use on shipboard for communication between ships or between ship and land. Here the position occupied by this system is unique. An expert operator is not necessary, as the engineer can take care of the generating apparatus and any one on the ship can use the telephone. There seems to be little doubt that for such purposes there will be rapid development, provided other influences do not interfere.

In connection with studies of the absorption of wireless signals due to atmospheric conditions, Mr. Fessenden has compared his observations with the weather maps of the government and is inclined to think there is some connection between the degree of absorption and the magnetic variation. This suggests that wireless signaling might offer to the Weather Bureau an entirely new means of making weather observations. If there is any connection between the absorption of wireless waves and the conditions of the upper layers of the atmosphere, which are no doubt controlling in important weather changes, careful comparison of the ease of transmission between suitably located stations should give valuable information regarding the atmospheric conditions; and to make this of practical value it would be only necessary to interpret it properly. If, as has been suggested, the absorption of the waves is due to large bodies or clouds of air in a peculiar condition, this condition, it may be expected, will exert its effect upon the weather. The Weather Bureau has for some time past been experimenting in making long-time predictions, and it has really met with thoroughly creditable success. For this purpose kites and pilot balloons are used. Why not study the relation between weather changes and this electric wave absorption with a view to determining what relations, if any, exist and making use of them when known?

The concluding portion of Mr. Fessenden's paper is devoted to a discussion of the relations between the Government and the private systems. He feels, perhaps naturally, that the restrictions which have been enforced, or are contemplated, have greatly retarded the commercial use of these two systems, and have made it impossible for any such system to be operated profitably to-day. This is an exceedingly important subject deserving the most careful study, not only of those directly interested in the two arts under discussion, but in those other branches of the electrical industry which may ultimately be affected by policies now followed. There are, of course, several sides to this question, and it is one which can not be decided offhand in an arbitrary manner. It would be well if every engineer would make himself familiar with what has already been done in this matter.

THE RESISTANCE EQUIVALENT OF ELECTROMAGNETIC RADIATION FROM A LINEAR OSCILLATOR.

In another column we publish an article by Mr. Oscar C. Roos on a subject entirely novel, perhaps, to most of our readers, "The Resistance Equivalent of Electromagnetic Radiation from a Linear Oscillator."

The author first cites the reasons for the divergencies found among the results obtained by various workers in attempting to give engineering data upon high-frequency phenomena present in the "verticals" used in the wireless art.

On the basis of a new law derived by him, which shows that any "vertical" of linear type vibrating at its lowest natural period or fundamental has a radiation resistance, R′, of forty ohms, he criticizes Professor J. A. Fleming's subsequent derivation of a similar law, when assuming a linear oscillator and a Hertz oscillator to be electrically equivalent.

The problem was attacked, as indicated, by Dr. John Stone Stone in a paper before the International Electrical Congress at St. Louis in 1904. The linear oscillator is decomposed into an infinite number of Hertz oscillators for all cases, and modifying assumptions pointed out for practical work. The practical formula for the present state of the art is given as a special case of a general formula. This special case, it is interesting to note, has been used in wireless engineering for three years.

The more general formula for R′ consists, when inspected, of an abbreviation for a series of discrete formulæ for definite regions of frequency, stated in units of the fundamental frequency of the vertical. It is evident that at all odd harmonics $R' = 40X$ ohms, where $X = 1, 3, 5, \ldots$ etc. As the author points out, it is at present impracticable to give an *a priori* treatment of the problem.

It is clearly shown that since ideal or practically simple harmonic vibrations have only of late been successfully produced in verticals and have been found to confirm old measurements of R′, we may infer that in at least one American system the damped waves hitherto used have behaved like undamped waves, both in regard to effective resistance and reactances introduced by radiation. This signifies great persistency in the intensity of the successive waves radiated from the vertical and shows that careful engineering methods have really a greater practical scope than the "cut-and-try" efforts which have made the development of radiotelegraphy spasmodically rapid, but to a great extent uncertain.

It is evident that in view of the importance of exact high-frequency measurements of voltage and current at the base of a vertical, to get empirical confirmation of calculations it is imperative to have a criterion of the accuracy of these readings.

Few electrical engineers are required to allow for variations in capacity or inductance with change of frequency. The wireless engineer must, however, be provided with accurately calibrated voltmeters, ammeters, standards of inductance and capacity, eliminating these effects. Frequencies of 60,000 cycles and upward are used and necessitate special methods of checking to avoid ever-present sources of error at these high-frequencies.

It seems desirable that the Duddell arc, when giving nearly pure sinusoidal oscillations, be used for checking the calculations on the vertical reactance and resistance. The high-frequency dynamo is not yet reliable for this work, and all final checks must be calorimetric. The voltage to ground and the current at the base of the antenna being known in two cases, there is obtained R′ and Z, the radiation resistance and the reactance of the vertical at the base, respectively.

Independent resonance measurements give as a check the value of the reactance when the frequency is known. This is a means, as we understand the author, of checking the uniformity of the constants of the antenna per unit length. We infer that the empirical correction of these assumptions and of those made under the MacDonald theory are included in the method as commercially applied, but withheld for the present.

The paper as a whole is timely and shows the present tendency to fusion of theory and practice in the more recent developments of electrical science. The electrical art is indeed becoming more amenable to methods of physical research which a decade ago were looked upon as scientific recreations. With this paper as a starting point the radiotelegraphic engineer is now in a position to make definite engineering tests on a very obscure and difficult problem.

The Society of Wireless Telegraph Engineers, founded in Boston, Mass., February 26, 1907, to which we have referred in our issue of June 13, has had this problem brought to its attention in a number of interesting papers during the past year. It is to be hoped that future papers of this character will receive more publicity through this society.

Annual Convention of the American Institute of Electrical Engineers.

The Twenty-Fifth Convention Opened at Atlantic City, N. J., June 29, with Good Attendance and Beautiful Weather—The First Day's Sessions.

(*Special to the* ELECTRICAL REVIEW, ATLANTIC CITY, N. J., JUNE 30.)

THE twenty-fifth annual convention of the American Institute of Electrical Engineers was called to order by President H. G. Stott at eleven o'clock, Monday morning, June 29, in the Sun parlor of the Hotel Traymore, at Atlantic City, N. J., under particularly promising conditions. The attendance was unusually good for an opening session, the weather could not have been finer, and the fact that all the papers to be presented had been printed and distributed to the membership beforehand is likely to bring out good discussions. As the number of papers to be read is large, it is probable that most of the sessions will be rather long. Indeed, the first session overran the allotted time by three-quarters of an hour; but, on the other hand, the afternoon session was half an hour late in getting under way, and was through half an hour before the time set.

Among those present were A. H. Babcock, San Francisco; H. H. Barnes, Jr., New York; B. A. Behrend, Milwaukee; A. W. Berresford, Milwaukee; James G. Biddle, Philadelphia; Charles Blizard, Philadelphia; Louis E. Bogen, Milwaukee; Morgan Brooks, Urbana, Ill.; George A. Damon, Chicago; F. E. Donohoe, New York; Thomas Duncan, Lafayette, Ind.; W. C. L. Eglin, Philadelphia; J. W. Fraser, Charlotte, N. C.; Albert F. Ganz, Hoboken, N. J.; C. M. Goddard, Boston; A. W. Henshaw, Schenectady, N. Y.; Carl Hering, Philadelphia; Cary T. Hutchinson, New York; Dugald C. Jackson, Boston; Edwin B. Katte, New York; A. E. Kennelly, Cambridge, Mass.; H. B. Kirkland, New York; A. A. Knudson, New York; John Langan, New York; R. D. Mershon, New York; Farley Osgood, Newark, N. J.; Ralph W. Pope, New York; Charles W. Price, New York; Calvin W. Rice, New York; Charles E. Speirs, New York; Calvert Townley, New Haven, Ct.; J. B. Whitehead, Baltimore.

The first session was opened by the introduction of Mayor Franklin P. Stoy, of Atlantic City, who in a humorous address welcomed the Institute to the city, extended the freedom of the town and guaranteed a continuance of the present good weather during the convention.

President Stott, after thanking the mayor for his courteous welcome, delivered the annual presidential address, the title being "The Evolution of Engineering," an abstract of which follows:

Eighty years ago Thomas Tredgold defined engineering as "The art of directing the great sources of power in nature for the use and convenience of man." The question naturally arises: Does this definition hold good to-day? Is it broad enough? If not, how can we better define the engineer's sphere of activity? If we accept Tredgold's definition as our standard, will we reach the position in society which belongs to us by right of education, achievement and highly developed power of logical deduction from facts observed and investigated?

Engineers may be divided into two classes: first, those who believe that the engineer should be restricted to a specific vocation, such as electrical, steam, hydraulic, pneumatic, or sanitary engineering, etc.; second, those who wish to see him take his place not only as an engineer but also as a public-spirited citizen and leader.

The score or more of divisions of electrical engineering which exist to-day are the necessary outcome of the consolidations of manufacturing and other interests into a few large concerns: they are the natural economic results of competition. As these consolidations have undoubtedly resulted in greater efficiency and, therefore, in reduced cost of production, there is every reason to expect a continuance of this evolution from the simple factory manufacturing only one article, to the complex one which manufactures many things. This process of segregation is evidently one of infinite application in all pursuits, tending strongly to an ever-narrower development of the individual, but at the same time increasing his efficiency to a maximum in his own particular specialty. This increase in efficiency, however, will cease if the engineer becomes so highly specialized as to ignore the necessity of keeping in touch with the entire sphere covered by his company, as the evolution of each branch must be synchronized with that of all.

The other class, to which the term "second" has been arbitrarily assigned merely to indicate its numerical inferiority, embraces all those who have broadened their field through self-education, experience, opportunity and natural adaptability for administrative work. The term self-education is used advisedly, as both classes are assumed to start with the same technical training, and as a matter of actual fact the second class almost invariably evolves from the specialists.

The second class is necessarily a restricted one, as, while the legitimate field of work of the engineer is extremely broad and almost unlimited, yet as a rule he has apparently decided to keep in the background and only come to the front when called. The result of this policy is that when the opportunity comes, the engineer is taken at his own valuation and passed over for others who, while not suffering from modesty, are lacking in engineering education and experience, and therefore are forced to call in engineers (to act in a subordinate position) to supply the incumbent's deficiency in the qualifications necessary for the office.

What is the cause of this anomalous situation? Has not the whole body of engineers some share in the blame? We have seen that there is to-day an inherent tendency to specialization in engineering, and that by far the greater number of our members are becoming experts in one or two subjects only, and that comparatively few attempt to keep in touch with the more general aspects of engineering. This condition is caused not so much by a lack of willingness as by lack of time and opportunity.

This centrifugal force acting on our profession has fortunately a nearly equal centripetal one which is found in such societies as the American Institute of Electrical Engineers, in which all can once more be brought back to a common centre on the common ground so clearly described in its constitution, which says that the object of the American Institute of Electrical Engineers "shall be the advancement of the theory and practice of electrical engineering and of the allied arts and sciences."

The conference held in Washington, D. C., last month, which was called by President Roosevelt to consider what steps should be taken to conserve our natural resources, was preceded by a series of conferences held by the presidents of the four national engineering societies, at which a series of broad resolutions were drafted and afterward presented at the conference as representing the opinions of 20,000 American engineers. The committee on resolutions presented a very able report to the conference, embodying practically everything the engineers had recommended, with one exception, as that particular item had already been covered in a bill introduced into Congress. The resolutions were unanimously adopted.

Several important deductions may be made from this incident. First, united recommendations after careful investigations of facts by engineers, on any public question involving engineering problems, will be not only courteously received but welcomed and highly appreciated by our state and federal governments. Secondly, the facts presented at this conference were of such a far-reaching and important nature that every member of this Institute should feel it is his duty carefully to study the able papers presented, and to further in every way possible the policy of preserving our natural resources. Thirdly, co-operation on the part of the four national engineering societies is absolutely essential to success in any movement of this kind; and, as a corollary, success is certain if we co-operate. Fourthly, if engineers are to take the place in society which belongs to them by right of education and training, they must take an active part in matters of general policy or civic interest, no matter how remote these matters may seem from Tredgold's definition of engineering.

Is it not the engineers' civic duty to take a more active part in public affairs, giving of their special knowledge freely, as may be required of them, at the same time insisting upon the same high ideals of faithful, honest and loyal performance of duties in public life as they have been accustomed to in their every-day work as engineers?

These suggestions are clearly outside the scope of this Institute as set forth in its constitution, so that to carry them out it may become necessary to organize a new society in which membership would be limited to members of the four national engineering societies, and whose object would frankly be to use all legitimate political methods to influence legislation on matters affecting engineering. Such a society could with propriety take up the consideration of many problems of which the public now hears only one side, simply because the engineer has maintained an attitude of reserve. Our large corporations and manufacturers are realizing as never before the benefit of publicity departments, not only for advertising purposes, but for the purpose of disarming adverse criticism by a calm statement of facts.

In conclusion, let us remember that if we wish to progress and assume our proper place in the world, we must be aggressive and not passive in allegiance to our engineering societies; that the day is long past for hiding our light under a bushel, and that instead of Tredgold's definition of engineering, the following more correctly expresses the position of the engineer to-day:

Engineering—The art of organizing and directing men, and of controlling the forces and materials of nature for the benefit of the human race.

Following the presidential address the two papers assigned for the first session were presented, that presented by F. G. Baum being read, in his absence, by Percy H. Thomas. Abstracts of these papers follow:

A paper entitled "Electricity as Viewed by the Insurance Engineer. Should the American Institute of Electrical Engineers Interest Itself in Fire Protection?" was read by C. M. Goddard, secretary of the Underwriters' National Electric Association. In this a brief review is given of the annual fire loss in this country, which for the year 1907 was $180,000,000, while the average for the past thirty-two years has been $134,000,000. Since 1860 the insurance companies have paid out $2,500,000,000 in losses, while the total property loss by fire has been $4,250,000,000 since 1875. There are approximately 300 insurance companies doing business in the country with outstanding risks of $30,000,000,000. The annual per capita loss by fire in Austria, Denmark, France, Germany, Italy and Switzerland varies from twelve cents in Italy to forty-nine cents in Germany, with an average of thirty-three cents. This may be compared with the average per capita loss in the United States of $2.47. Fifty per cent of the fires are due to faults of management, which include all sorts of easily avoidable conditions likely to cause fire hazard. These figures indicate the importance of reducing the fire hazard in this country and justify the continuous efforts which the Underwriters' association is making in this direction. Mr. Goddard explained the requisites of a good fire-protection engineer and insisted upon his honesty of purpose, and pleaded for co-operation of the electrical engineer with the former. He said that electricity may become a serious fire hazard, but due to the regulations which have been enforced the insurance companies believe that any undue hazard from electricity has been and is being guarded against and that electric power gives us to-day the safest illuminant and the safest source of power we have.

F. G. Baum presented a paper entitled "Water Power Development in the National Forests—A Suggested Government Policy." Recently the government has given permits to companies proposing to make power developments on condition that the permits be revokable at the pleasure of the Secretary of the Interior and that there be a conserving water royalty charge by the government on the power output of the plant. Temporary permits are objected to by power companies, and objection has also been raised to the conservation charge when it is based on the output of the plant. The author, after discussing the importance to the country of proper development of the water powers, suggests that a proper conservation charge can be made only on the basis of the cost to the government of that which is furnished by the government. He thinks that the proceeds from any particular privilege shall not be devoted to any other watershed or section nor to any purpose except the particular privilege asked for. The conservation charge would have a maximum limit at any given time, which could be determined by calculating the yearly cost of the conservation to the government. This charge can be fixed for a period of, say, ten years, when a new adjustment may be made and a new charge made yearly to meet the changing cost of maintenance. The question of the proper conservation charge is entirely a separate matter from the charge to be made for lands and rights of way for development, and the two matters should be kept distinct. Rights of way and lands necessary for the development should be charged for on a fair basis of value as would be determined if the lands belonged to private parties and a value had to be set on them for power purposes by a court or a commission. Such lands should be deeded outright by the government to the power company, and the only changing condition then, as time goes on, would be the yearly conservation charge.

President Stott then introduced President-elect L. A. Ferguson, who asked for a continuation of the support which had been given his predecessors and outlined certain phases of work which he thought the Institute might take up with profit. It should endeavor to instruct the younger members in engineering matters. It should bring into closer touch with its active work those engineers who have taken up executive duties and who are now generally only associates and not members. It should endeavor to interest the leading members of other engineering societies. At the present time there is much duplication of work in many localities because of the different electrical societies there. These should be brought together under the Institute leadership. In conclusion Mr. Ferguson emphasized the degree to which the success of the Institute, as a whole, depends upon its members individually.

The discussion on the papers which had been read was then opened by J. H. Finney, who took up Mr. Baum's paper somewhat in detail and disagreed with all the latter's important conclusions. Mr. Finney believes that the resources of the country belong to the country as a whole and the benefits derived from each of them must not be confined to its section. He quoted, with approval, from President Roosevelt's opening address before the recent conservation conference, in which the same stand was taken, and in which it was asserted that we should consider ourselves as the trustees of resources upon which future generations will depend, and we should so manage as to harmonize the work of private capital, of the state and of federal governments. Taking up in detail Mr. Baum's proposals for government conservation charges, Mr. Finney contended that they were not in accordance with practice in other lines of business and that practical conditions make a fixed rate desirable. The policy of the government may be summed up in the phrase "Equal justice to all."

E. R. Taylor also dissented from Mr. Baum's views, holding that the whole country should profit from the resources of any favored section.

Professor J. P. Jackson, referring to President Stott's address, said that while the engineer alone might be backward in asserting himself, as a body, engineers carry weight. Turning then to Mr. Goddard's paper, he said this was most timely. He suggested it might be advisable to have a committee of engineers to consider means of reducing the tremendous economic waste which now takes place from fires.

P. V. Wells, of the Forest Service, outlined the general policy of that service with respect to the protection of water powers. He took issue with Mr. Baum, saying the latter confused the policy of the service with the desires of Congress. The Forest Service does not like the present system of revocable permits and would like to make them irrevocable, if not violated, for a period of, say, fifty years. This Congress will not allow. The service now specifies the charges which will be made, so far as it can, and it requires that the permits be used, setting times for the beginning and completion of the work. Uniform charges are best, for many reasons. Mr. Baum's analogies do not hold, for land is free to settlers and irrigation is furnished them at cost, while companies seeking a profit from irrigation are required to pay for it. The service recognizes the value of storage and does not charge for the water stored, but it does charge for the head developed by such storage. The charges of the service are too low to obstruct any development, but give the developers of the most favorable sites the best chances of making a profit.

A. H. Babcock said the various speakers seemed to misapprehend Mr. Baum, who merely took the stand that when the people of a district develop its resources they should enjoy the benefits thereby secured. Taking up Mr. Goddard's paper, he said that he had watched the fires started by the San Francisco earthquake, and it was a remarkable fact that these had all started in the section of the city fed by the large storage battery of the United Gas and Electric Company through its underground wires. In the outlying districts the power was cut off by the breaking of the pole lines and there were no fires.

Dr. C. P. Steinmetz said he agreed with Mr. Baum that the present method of making conservation charges is not just, but he did not, therefore, admit the justice of the latter's proposed method. The argument which he makes is the very one now being used with much effect against the setting aside of forest reservations. The people in distant sections are told that they will not be benefited. But the reverse is the truth. A water development in Maine saves fuel there and helps to keep the price of coal down; and the price of iron in San Francisco is dependent upon the cost of coal. If local interests only are conserved there can be no excuse for governmental aid. There are two features to be considered: the development of our resources as completely as possible and the encouragement of private capital in the work.

Regarding Mr. Goddard's paper, Dr. Steinmetz said the question is really broader than a mere fire risk. There is the risk to life and the risk to capital. It would be proper for the Institute to take the matter up in its broadest aspects. There might be a committee for considering the safeguarding of all interests, or it might be better to secure and publish papers on such topics, as it is exceedingly difficult to lay down rules applicable to all situations. What is not good practice in cities may be good practice in small towns.

L. A. Ferguson said Mr. Babcock's statement regarding the San Francisco fires was remarkable, to say the least. The Commonwealth Edison Company, of Chicago, had tried overhead high-tension wires in the outlying districts and had abandoned them as bad practice. He thoroughly agreed with Dr. Steinmetz.

Mr. Babcock replied that he had not attributed the fires to the underground wires, but had merely called attention to a remarkable coincidence.

William McClellan said that the destruction of our forests has ruined many good water powers, and those which have escaped should help to rehabilitate the ones damaged.

C. F. Scott commented upon President Stott's address, saying the Institute should endeavor to co-operate with other engineering societies and thus secure a greater influence.

The first session was then adjourned.

MONDAY AFTERNOON'S SESSION.

The second session was called to order at 2.30 Monday afternoon, and the four papers on the programme were read and discussed.

In a paper entitled "A Study of Multi-Office Automatic Switchboard Telephone Systems," W. Lee Campbell discussed the enormous economic waste which the wire, cable and conduit equipment of the telephone system involves, the reasons which make this waste expedient in manually operated systems, and how it can be reduced in systems employing automatic switchboards. Of the three items of cost —that of apparatus, that of office and buildings, and that of wire, cable and conduit—the last is the largest. Under usual circumstances this part of the system costs more than the other two parts combined, and not infrequently it represents two-thirds of the entire first cost. The author states that in the average telephone system, containing but one central office, nine-tenths of the cable and wire plant is idle during the peak of the load and ninety-eight per cent is not in use under average conditions. Party-line service is but a partial remedy for this condition, and the only method known of materially reducing the great economic waste thus represented is to divide the central office up into a number of smaller offices. The saving which may be effected in this way depends upon local conditions. It is evident that with a number of central offices well distributed the subscribers' lines will be considerably shorter, so that it will only be necessary to have a sufficient number of trunks between offices to handle the maximum business. On the other hand, a single large central office usually costs less to operate. The author then constructs an arbitrary curve showing the probable number of calls per day per line on systems of different sizes, and on this basis he constructs other curves representing various items in first cost and operating expense for systems varying from 1,000 to 14,000 lines. In this way he compares the manual system with the automatic. It was found that the cost per line of manual equipment increases rapidly with the size of the office. With the automatic system this increase is relatively slow. If the equipment is for 5,000 lines or more, the space occupied by the automatic system is only about half that of the manual, and with a station of 14,000 lines, the total cost of the office equipment of the automatic system is about equal to that of the manual. Curves are given showing the various items in the cost of operation of the two systems for central offices of different sizes. From these curves it is found that when the ultimate number of subscribers which may be expected in one-office district in fifteen years does not exceed the capacity of a single multiple board—that is, 10,000 lines—and there is no concentrated group of subscribers at a considerable distance from the best location of the single office, a one-office system will be the most economical when manual equipment is used. However, there are conditions under which it is profitable to divide such systems, as the saving and annual charges on the wire and conduit will more than offset the increase in the central office expenses. Roughly speaking, an economical arrangement of the average manual system will include offices not much less than two miles apart. There is an objection, however, to the multi-office manual system on account of the slower service given and greater liability of mistakes, but there are no such objections to the divisions of the automatic systems; and, on the other hand, this division can be carried much further than in the manual system with a much greater saving in wire and conduit. Several assumed cases are then considered and the most satisfactory arrangement for each is found. For example, a particular 50,000-line system is divided into five main offices, one of which is subdivided into eight branch offices, and the other four into five branches each. This gives a system with an ultimate capacity of 100,000 lines, which can be handled with instruments having five numbers. The author then dwells upon the advantages of the multi-office system, such as the facility with which this is expanded or can follow the shifting of the population. Such a system is easily adapted to meet any unexpected demand.

The discussion was opened by the reading by P. H. Thomas of two communications dealing with the subject of the paper. The first, from A. B. Smith, said the writer had long hoped that the automatic telephone would solve the city telephone problem. It now seemed to have reached that stage, as the multi-office system described offered many advantages. However, it seemed to involve a disadvantage in requiring a system of heavy trunks. Would not an automatic trunking switch solve the whole problem?

The second letter was from John Wicks, and it agreed, in general, with Mr. Campbell's views. Now that the automatic system offered party line service—that is to say, inexpensive service—it had removed one of the serious obstacles to its wide use. What is wanted is an inexpensive trunking system, and this, too, is now available in the two-way trunks, which are good for service both in calling and answering.

Professor Morgan Brooks said that it is wrong to plan for a system which will keep the wires in use the greater part of the time. What is wanted is a system which will always have the wires free when a call is to be made. To this end the automatic assists, as it saves time in disconnecting.

L. E. Hurtz emphasized the great saving due to the switching units which make small exchanges possible.

R. A. Fessenden, in a paper entitled "Wireless Telephony," gave a brief historical review of the development of wireless signaling. The first period began with the work of Henry in 1838 and ended with 1902. The second period, beginning with 1902 and continuing up to the present time, has been marked by the gradual abandonment of the damped-wave coherer system and the substitution of the elements of the sustained-wave nonmichrophonic contact type. A good deal of the new apparatus devised in this work is described. Regarding the possibilities of this system, Mr. Fessenden thinks there is no immediate prospect of its taking the place of local exchanges, but there is a good field for it for long-distance lines. For transmarine work and communicating between ships it is exceptionally well suited. Regarding the range of transmission, there is little difficulty governing distances of 100 miles. Beyond this atmospheric absorption begins to make itself felt. The author also explains his views of the retarding effect which the various governments of the world have exerted on the development of this important new art. There was no discussion on this paper.

A paper by Dr. A. E. Kennelly and S. E. Whiting on "The Measurement of Rotary Speeds of Dynamo Machines of the Stroboscopic Fork" was read. This calls attention to the use of the stroboscopic fork by Dr. C. V. Drysdale and describes the authors' work in developing this instrument to meet their own particular needs. An electrically operated fork is used, upon the sides of which are two movable weights shifted by means of cords and wheels and with a pointer indicating the change in the pitch of the fork with the position of the weights. The slit screens are carried on the ends of the fork and through the slits a peculiar target is viewed. This contains, first, a square, then a pentagon, a hexagon, a ring of fourteen marks, and a similar outer ring of eighteen marks. By viewing this screen through the slits the speed can be easily read within one part in 1,800. Attention is called to the fact that there is no patent on the stroboscopic method of measuring speeds, and it is free to any one who wishes to use it.

The discussion on this paper was opened by J. B. Taylor, who said that the engineer is often not so much concerned with actual speeds as with differences in speed, and he described the stroboscopic method used at Schenectady for this purpose.

Professor H. A. Perkins said that he used three forks of different pitch, and by counting the number of coincidences which occurred when any one was in use the range could be extended 150 revolutions each way. This, taken with the subdivisions of the frequency into one-half, one-quarter, etc., gave practically the entire range from nothing to the highest frequency.

Dr. C. H. Sharp said the instrument

exhibited by Dr. Kennelly was not only very accurate, but portable, and hence would be most useful in practice.

C. E. Waddell, in a paper entitled "Notes on the Electric Heating Plant of the Biltmore Estate," described the electric heating systems which have taken the place of various other devices in the Biltmore house. The reasons for the change were, first, the objection to burning soft coal and the high price of anthracite coal, and the desire to do away with the hauling of fuel and ashes, with the incident noise and dirt. Electrical energy was available at eight and one-half mills per kilowatt-hour, so that this made possible a comparison of the economic features of the coal and electric systems. Due to the somewhat irregular character of the loads, the electric system is not under such a great disadvantage as would at first be assumed. The hot water for the house is heated in a boiler three feet in diameter, five feet long, containing twenty flues, each of which encloses a five-kilowatt heating element. The laundry has been completely fitted up with ironing, dry and washing apparatus, with a total rating of sixty-seven kilowatts. The author concludes that electric heating has suffered from the fact that its economic possibilities have usually been considered from its thermal-unit value, and that the lesson to be drawn from the Biltmore installation is that a careful analysis of all the conditions may disclose the fact that while theoretically a disparity exists, nevertheless, economy may accrue due to the better operating conditions. He also takes occasion to state that certain of the auxiliary appliances accepted as standards in lighting work will have to be abandoned or remodeled for heating purposes. Fireproof or asbestos-covered wire is to be preferred to rubber, even in conduit installations.

The discussion was opened by P. H. Thomas, who said that a large heating equipment, such as described, became a real engineering problem and should be treated as such.

A number of questions were asked, such as the cost of electric heating as compared with fuel, details of the electric steam boiler and other uses of electricity. Mr. Waddell replied to these, but nothing new was brought out.

The second session was then adjourned.

In the evening a reception was held at the Casino, a large attendance being present.

W. H. B., Jr.

The First Year's Work of the New York State Public Service Commission.

On July 1 the Public Service Commission for the First District of New York state, created under the Public Service Commissions Law, was one year old. It has done noteworthy work in two fields during the year—those of lighting and transportation, substantiating Governor Hughes' belief in recommending its creation to succeed the old Rapid Transit Commission and the State Commission of Gas and Electricity.

William R. Willcox, chairman of the commission for the First District, has stated that, in spite of great difficulties, he is satisfied with the results of the work done by the commission. A few of the most notable results accomplished through the work of the commission are better express and local service in the New York subway, and more frequent service on all the elevated roads and greatly increased service on all the more important surface lines. The car movement over the Brooklyn Bridge has been materially accelerated.

Evils of financial mismanagement and consequent deterioration in operating service have been disclosed, and the experience gained by the investigations has resulted in action looking toward the prevention in the future of the abuses of the past.

The commission proposes to reform the system of accounting, and will make such changes as will compel companies to make monthly allowances for depreciation and to set aside funds for the replacement of worn-out rolling stock.

After much study the commission has decided that where a field is monopolistic —that is, where a monopoly, properly regulated, can best serve the needs of the community—it is inadvisable to encourage the entrance of competitors. It is believed that the soundness of this principle will be indicated in the future by the improvement in service of the public service corporations.

The commission has perfected plans for the Fourth avenue subway in Brooklyn, and has taken definite steps toward the building of new subways and elevated lines.

In the field of gas and electricity the commission has done effective work in the testing of gas and electric meters. The electric light companies, at the solicitation of the commission, have resumed the giving of breakdown service to periodical consumers.

The New Holland-American Liner Rotterdam.

On Wednesday evening, June 24, a large company of representative business men and prominent citizens were the guests of the Holland-American Steamship Company at a dinner on the new steamship Rotterdam, which has just been placed in service. This is the third largest transatlantic liner, and its appointments are exceptionally complete. It is electrically lighted throughout, provided with a remarkable system of ventilation and heating, and electric elevators, telephones, heating and cooking devices render a trip very luxurious.

This vessel is the fourth of the same name to have been built and employed in transatlantic service by the Holland-America line. The first Rotterdam appeared in 1872 and was a steamer of 2,000 tons. The second was a four-masted steamer of 4,500 tons, and appeared in 1885. The third was brought out in 1897, was of 8,300 tons, and was the first twin-screw steamer of the line. The new Rotterdam of 1908, with a tonnage of 24,170 and a displacement of 37,190 tons, eclipses all her earlier namesakes not only separately but also collectively, the single tonnage exceeding the total of the three predecessors.

In point of luxurious appointment and accommodations the Holland-American company considers this craft "the last word" in ocean liners.

Disagreement in Insurance Companies' Suit Against Denver Lighting Company.

During 1907, in Denver, Col., a low-potential wire was crossed by a high-tension conductor and a series of fires, alleged to be on the circuit of the low-potential wire, were started. A number of dwellings and a church were burned, and it was held that in each case the flames had started around the electric light fixtures. The insurance companies settled the claims, took the subrogation, and brought suit against the lighting company for the recovery of $30,000, the amount of insurance paid upon the church loss.

The principal point involved was whether the electric light company had protected its wires by properly grounding them to carry off any accidental high-tension currents. The insurance companies had experts from Chicago and Cleveland to testify that if the low-tension wires had been properly grounded no fire could have resulted, but the company had experts to testify that the ground was of little value except for protection to life, and the jury disagreed, the voting being four to eight against the insurance companies. Barger & Hicks, of Chicago, and Sylvester Williams, of Denver, represented the insurance companies. Another trial will be held.

AMERICAN RAILWAY MASTER MECHANICS' ASSOCIATION.

FORTY-FIRST CONVENTION, HELD AT ATLANTIC CITY, N. J., JUNE 22 TO 25.

The first session of the forty-first annual convention of the American Railway Master Mechanics' Association was called to order at 9.30 A. M., Monday, June 22, by the president, William McIntosh, superintendent of motive power of the Central Railroad of New Jersey, at Atlantic City, N. J. Prayer was offered by the Rev. J. H. Setchell. The association was welcomed to Atlantic City by Mayor Stoy, and response was made on behalf of the association by J. F. Deems.

In his presidential address Mr. McIntosh emphasized the importance of careful selection in the membership of the association, and indicated the necessity ultimately of the Master Mechanics' and Master Car Builders' Associations being consolidated into one powerful, united, representative organization. The progress of the times, the conditions of the work and the character of the problems demand this step.

The report of the secretary, Joseph W. Taylor, showed that there were 862 active members, nineteen associate members and thirty-seven honorary members, a total of 918. The receipts of the secretary's office for the year had been $5,200.33, and the expenses $5,200.33, with unpaid dues amounting to $1,440. The report of the treasurer showed a balance on hand of $1,912.72. The secretary announced that the executive committee recommended that the annual dues for the present year should be fixed at $5, the same as last year, which recommendation was approved.

The report of the committee on "Mechanical Stokers" was presented by J. F. Walsh. This was the subject of considerable discussion, and on motion the present committee was continued and made a standing committee.

The report of the committee on "Blanks for Reporting Work on Engines Undergoing Repairs" was presented by Theodore H. Curtis, chairman.

The report of the committee on "The Proper Width of Track on Curves to Secure the Best Results with Engines of Different Lengths of Rigid Wheel Base" was presented by F. M. Whyte. This report was received and the subject continued as recommended by the committee.

The paper entitled "Fuel Economy" was submitted by W. E. Squire, and a topical discussion held on the subject "The Smoke Nuisance."

This was followed by a topical discussion on "Alloy Steel."

The report on "Washing Out Locomotive Boilers" was then presented by H. T. Bentley.

The second session was called to order at 9.30 A. M. on June 23.

J. F. DeVoy presented the report of the committee on "Castle Nuts."

The report on "Apprenticeship System" was presented by C. W. Cross. On motion it was resolved that the report of the committee be adopted and that principles recommended by the committee be endorsed by the association as recommended practice, and substituted for the "Code of Apprenticeship Rules" adopted in 1898.

The report of the committee on "Superheating" was presented by H. H. Vaughan. This report was accepted and the committee continued.

The report of the committee on "Mallet Articulated Compound Steam Locomotives" was presented by J. E. Muhlfeld.

The paper by A. W. Gibbs, entitled "Tests of Briquetted Coal," was presented.

The third session was called to order at 9.40 A. M., June 24. The first report presented was that of the committee on "Size and Capacity of Safety Valves," by F. M. Gilbert, chairman.

The report on "Revision of Standards" was read by W. H. V. Rosing.

The topic, "Standardization of Locomotive Parts" was discussed, the discussion being opened by G. R. Henderson.

This was followed by the report on "Various Designs of Four-Cylinder Compound Locomotives in Service."

After the report of the committee on nominations was adopted the election of officers for the ensuing year was held. The following officers were elected: President, H. H. Vaughan, assistant to vice-president Canadian Pacific Railroad; first-vice president, G. W. Wildin, mechanical superintendent New York, New Haven & Hartford Railroad; second vice-president, C. E. Fuller, assistant superintendent motive power and machinery Union Pacific Railway; third vice-president, J. E. Muhlfeld, superintendent motive power and machinery Baltimore & Ohio Railroad; treasurer, Angus Sinclair, New York city; executive members, H. T. Bentley, Chicago & Northwestern; T. Rumney, Erie; T. H. Curtis, Louisville & Nashville.

Westinghouse Reorganization Plan.

The United States Court at Pittsburg, Pa., on petition by receivers of the Westinghouse Electric and Manufacturing Company, has entered an order directing the payment of interest due July 1 upon the funded debt and floating debt of the company, and also interest due August 1 on collateral notes of the company. This amounts to $500,000 interest due on bonds and notes, due on July 1, and $180,000 interest on a $6,000,000 loan, due on August 1. The receivers stated that they had sufficient funds to meet these obligations.

At the meeting of the readjustment committee on June 26 it was stated that the details of the circular to be issued to stockholders and bondholders were practically worked out and that the circular would be issued during this week. It was also stated that the merchandise creditors' plan, after a necessary delay to complete details and secure the small remaining amount of subscribers to new stock, would be put into effect about September 1. The two months' extension will enable the committees to perfect the reorganization plan proposed, and it is believed that before September 1 announcement will be made regarding the changes in the personnel of the company.

Great satisfaction is expressed over the completion of the important contract recently announced with the Bergmann Electric Company, of Germany, whereby that company will construct a large plant for the manufacture of Westinghouse single-phase apparatus. The company will install the Westinghouse electric traction system in Germany, and the combination has been formed for the purpose of furnishing the requirements of the Prussian state railway administration, which has decided to electrify the steam railways, $12,500,000 having been appropriated to begin the work.

American Electrochemical Society.

The fall meeting of the American Electrochemical Society will be held in New York city, probably in October. The dates contemplated are October 30, with a session at the College of the City of New York, and October 31, with a session at the Chemists' Club, 108 West Fifty-fifth street.

International Congress on Electrical Units and Standards.

The following memorandum as to the proposals to be laid before the Congress on Electrical Units and Standards to be held in London in October next has been prepared. The congress will assemble on October 12.

The general object of the International Congress on Electrical Units and Standards, which is to meet on the invitation of His Majesty's government in London in October, 1908, is to consider and advise as to the steps which should be taken to bring about agreement in the definition of electrical units which form the basis of legislation in different countries, and in the methods of constructing and employing the electrical standards necessary to give effect to these definitions.

It is hoped that the delegates to the congress may find themselves able to embody their conclusions in draft articles which might be commended to the several governments represented as a basis for uniform legislation and administration in relation to electrical units and standards.

The fundamental units of electrical measurement are the ohm, the ampere and the volt. Of these two are primary units, being independent, and the other secondary or derived. It is generally agreed that the ohm should be accepted as one of the primary units. There is some difference of opinion as to whether the ampere or volt should be the second. This point will be one for the conference to consider.

Again, the ohm is realized by means of the resistance of a column of mercury of definite dimensions, the ampere by means of the electrolytic deposition of silver, and the volt by aid of a standard cell.

If this method of realizing the units be accepted by the congress, specifications for the ohm and ampere will call for consideration, while the standard cell must be selected and the method of setting it up prescribed.

In view of the scientific questions raised in connection with each of these matters, including also the choice of the two primary units, it will be suggested at an early meeting of the congress, should such a course appear to be desirable, that the congress should appoint a small technical commission of experts to discuss the question, and report thereon to the congress.

The congress will also be asked to consider the best methods of securing uniformity of administration in the future, and for arriving at a decision on any questions left undecided at the close of the congress.

It is desirable to have some definite questions before the congress, and with this object the following propositions embodying conclusions arrived at by the representatives of the various National Standardizing Laboratories which met at the Reichsanstalt in 1906, and which are also generally in accordance with the decisions of the Chicago congress held in 1893, will be brought forward as a basis for discussion:

1. That the ohm shall be the first primary unit.
2. That the ampere shall be the second primary unit.
3. That in consequence the volt shall be treated as a secondary or derived unit.
4. That the international ohm be defined as the resistance at the temperature of melting ice of a column of mercury of uniform cross-section terminated by planes at right angles to its length 106.3 centimetres in length and 14.4521 grammes in mass.
5. That the international ampere be defined as the unvarying electrical current which, when passed through a solution of nitrate of silver in water, deposits silver at the rate of 0.001118 gramme per second.
6. That the international volt be defined as that electromotive force which, when applied steadily between the ends of a conductor of resistance one international ohm, produces a current of one international ampere.
7. That the Weston cadmium cell be adopted as a convenient standard of electromotive force, having, at a temparture of seventeen degrees centigrade, an electromotive force of .... international volts, but that it is undesirable that the number representing the electromotive force of this cell should be the subject of legislation in any country.
8. That specifications dealing with the methods of setting up mercury standards of resistance, of realizing the ampere by the deposition of silver and of preparing standard cells, be issued with the authority of the congress, and that for this purpose a technical commission be appointed to prepare these specifications.
9. That the congress consider and advise as to the best method of securing uniformity with regard to the fundamental electrical standards for the future.

Exports of copper for the first five months of 1907 were 66,044 tons; for the first five months of 1908, 133,872 tons. Imports of copper for the first five months of 1907 were 56,250 tons; for the first five months of 1908, 36,600 tons.—*Copper Gossip.*

FINANCIAL REPORTS OF ELECTRICAL COMPANIES.

TOLEDO RAILWAYS AND LIGHT COMPANY.

The report of the Toledo (Ohio) Railways and Light Company for the month of May and five months ended May 31 shows May gross of $198,973; expenses, $109,444; May net, $89,529; other income, $81; total income, $89,610; charges and taxes, $71,719; May surplus, $17,891. Five months' gross, $1,028,607; expenses, $574,930; five months' net, $453,677; other income, $2,774; total income, $456,-451; charges and taxes, $348,373; five months' surplus, $108,078.

DETROIT UNITED RAILWAY COMPANY.

The report of the Detroit United Railway Company, Detroit, Mich., for the month of May and five months ended May 31 shows May gross of $599,643; expenses, $365,875; May net, $233,768; other income, $4,464; total income, $238,-232; charges, $135,661; May surplus, $120,571. Five months' gross, $2,649,-635; expenses, $1,726,116; five months' net, $923,519; other income, $23,944; total income, $949,463; charges, $675,-794; five months' surplus, $271,669.

ELECTRIC STORAGE BATTERY COMPANY.

The preferred and common dividends on the stock of the Electric Storage Battery Company have been cut from one per cent quarterly to three-quarters of one per cent. This is the second cut in six months. Three months ago the rate was reduced from one and one-quarter per cent to one per cent.

While business has fallen off very greatly since last October, an improvement has been manifested within the last few weeks. A number of inquiries have been received from large customers, and several orders have been taken. While the company's shipments are not as great as those of a year ago, the amount of orders on its books for future delivery is as large as last year's.

MONTREAL STREET RAILWAY COMPANY.

The report of the Montreal Street Railway Company, of Montreal, Quebec, for the month of May and eight months (October 1 to May 31) shows May gross of $313,678; expenses, $169,723; May net, $143,955; charges, etc., $61,801; May surplus, $82,154, compared with a May surplus of $75,823 in 1907. Eight months' gross, $2,341,551; expenses, $1,-485,623; eight months' net, $855,928; charges, $385,788; eight months' surplus, $470,140.

NEW WEST EXCHANGE AT CINCINNATI, OHIO.

BY J. E. PEAVEY.

The telephone system of Cincinnati, Ohio, scores another improvement in the new West Exchange, located at 930 York street. Early in 1907 the Cincinnati & Suburban Bell Telephone Company decided to further improve its telephone system in that city and provide for the rapidly increasing business by building an entirely new exchange to take the place of the old West office, located at Eighth and Freeman avenues. Consequently a new exchange centre for the district was obtained, and without delay an exchange building erected with sufficient capacity to accommodate the largest type of multiple relay switchboard with auxiliary apparatus and ample district offices.

The new building has three stories and a deep, well-lighted and ventilated basement.

FIG. 1.—NEW WEST EXCHANGE OF THE CINCINNATI & SUBURBAN BELL TELEPHONE COMPANY, CINCINNATI, OHIO.

As shown in Fig. 1, the building is very substantially constructed of blue granite and Shawnee speckled brick, and is fireproof throughout. The interior framing is of steel and all partitions are of tile and the floors concrete, with staircases constructed of steel and white Italian marble. Corridors and vestibules are also of white Italian marble, with floors of a neat mosaic design. The only wood entering into the construction is used for floors on the concrete to soften the tread, doors and a few minor details. The windows in external walls exposed to adjoining property have metal casings and wired glass, thereby insuring against fire from external sources. The entire third floor of the building is used for the switchboards and as an operating room. The second floor contains the apparatus room and operators' quarters. The ground floor is used entirely for district offices and the basement contains the heating system and exchange power plant, cable runway and various accessories belonging to a first-class building of this character. All wires enter the building through a tunnel from the exchange manhole in the street. After the cables enter the basement they are supported on a unique runway or rack to a point directly beneath the main frame, where they rise into the main frame terminals. Fig. 2 shows this cable rack or runway in the basement.

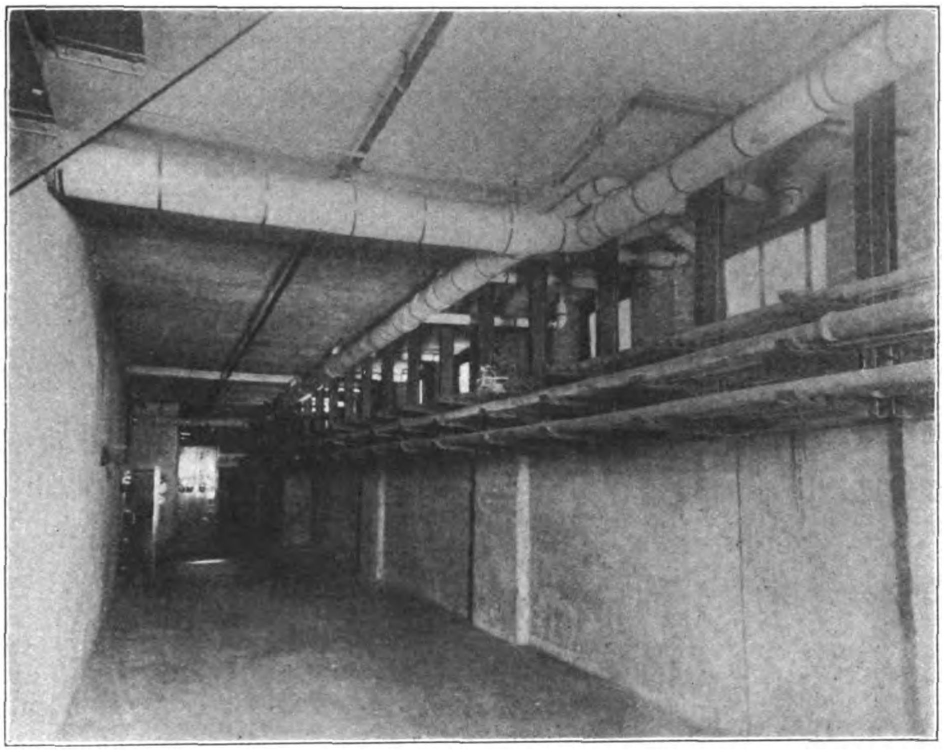

FIG. 2.—CABLE RUNS IN SUBWAY—WEST EXCHANGE OF THE CINCINNATI & SUBURBAN BELL TELEPHONE COMPANY.

Standard Western Electric equipment is used throughout. The switchboard has an ultimate capacity of 9,600 subscribers' lines and a present equipment of 5,000. Fig. 3 is a view of one corner of the operating room, showing a portion of the front of switchboard. Fig. 4 is a rear view of the power switchboard, and gives some idea of the generally substantial character of the construction and assembly throughout this exchange installation.

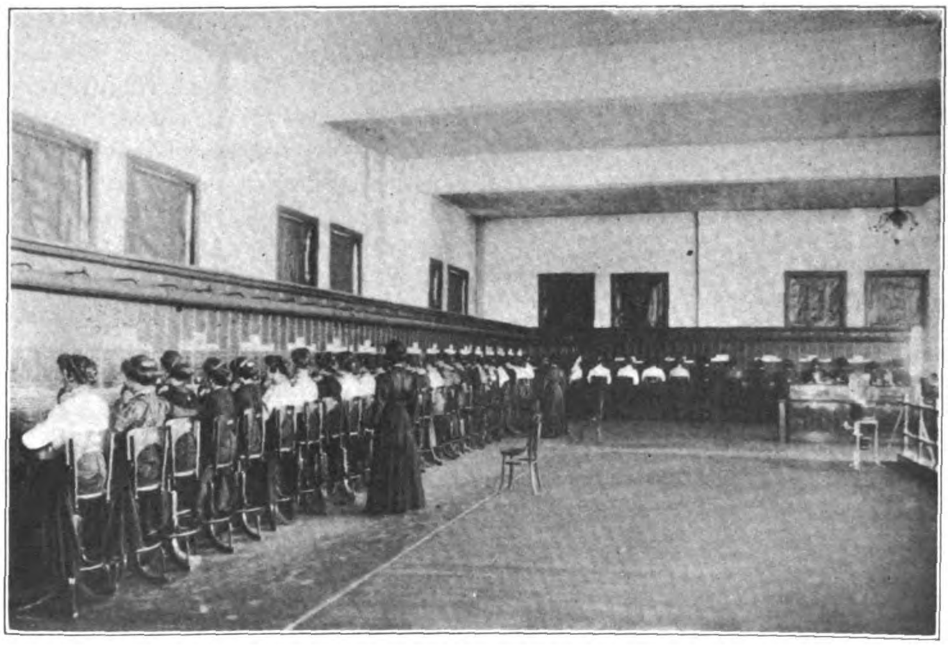

FIG. 3.—WEST EXCHANGE OF THE CINCINNATI & SUBURBAN BELL TELEPHONE COMPANY—FRONT OF SWITCHBOARD.

The exchange possesses several distinct features of importance, the principal of which is the use of forty-eight volts on all cords for transmission purposes—both local and toll. This is the second office so equipped by this company, forty-eight volts having been adopted as a standard for all offices having a comparatively long substation loop. Machine or automatic ringing from the trunk or "B" operator position is also used, which materially reduces the "don't answer" reports and otherwise aids in economical operation. The interior arrangement of the exchange, both from an artistic and operating standpoint, is very complete, every facility for operating and maintaining the plant having been carefully worked out and provided for.

This being the eighth large exchange built by the Cincinnati & Suburban Bell

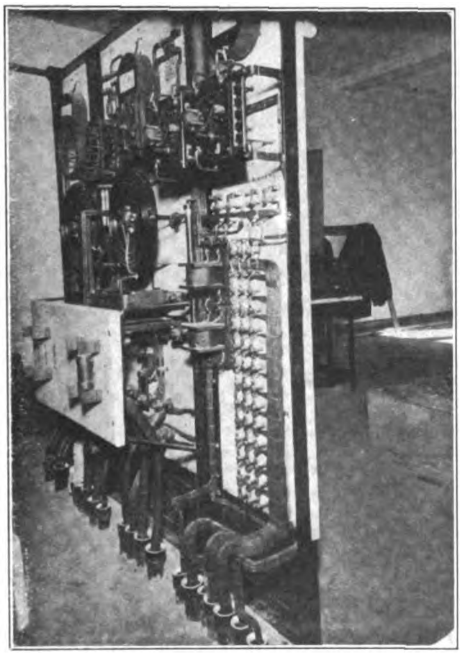

FIG. 4.—REAR OF POWER BOARD AT WEST EXCHANGE.

Company in the past five years, as a consequence a large fund of practical information on modern exchange design and construction was at the company's disposal. The transfer or cutting-over from the old to the new exchange was accomplished at 2 P. M. on Saturday, February 15, 1908, and required just 100 seconds. So successful was the cut-over that not one of the eleven other exchanges in the city was aware when the transfer was made. Considering the hour of the day, with its operating load, this is considered quite a feat.

All credit for this handsome exchange and its successful completion must be given to B. L. Kilgour, general manager of the company, who gave considerable personal attention to the engineering work; also to T. C. Reed, superintendent of the cable department, for the thorough workmanship that permitted the exchange to be transferred from the old to the new building without a single case of trouble or complaint.

THE TUNGSTEN LAMP.[1]

BY E. F. TWEEDY.

In considering the commercial effects of the introduction of the tungsten lamp the present, together with the possible users of electric light, may be divided into three classes according to their probable relations to this new illuminant. The first class consists of existing customers who are now using electric light at what might be termed the "point of saturation," based on the present standard of illumination, thereby reducing their watt capacity and consequently decreasing the revenue of the central station. To illustrate this a concrete example of this class will be cited. The United Cigar Stores Company has consistently recognized the advertising value of brilliantly lighted stores. To carry out this idea effectively they have been large consumers of electricity, their total outlay for electric lighting on Manhattan Island alone during the year 1907 being about $80,000. By means of the tungsten lamp they now expect to reduce this expense by nearly one-half, without sacrificing in the slightest degree their present high standard of illumination.

The second class is likewise composed of present consumers, but in their case the illumination is below the "point of saturation" above referred to, for the present standard of illumination. This class has limited its quantity of illumination, the reason for this being largely one of dollars and cents. The question now arises as to whether this class will utilize the tungsten lamp for the purpose of securing the same illumination for less money, or to secure a greater amount of illumination for the same money. The latter alternative seems more probable, but central stations can not wait passively for such a result. It is time for active work among such a class of customers, in order to point out to them the advantages which they will derive from a greater amount of illumination, now that a cheaper source of light is at hand. Unless this is done central-station income from this class will probably be diminished, at least temporarily. For the present, while the tungsten lamp is made only in sizes of comparatively high candle-power, it does not seem likely that it will replace the carbon lamp in domestic lighting. It is very probable that multiple lamps of smaller candle-power will soon be upon the market; in fact, a 110-volt tungsten lamp of twenty candle-power, consuming twenty-five watts, was exhibited at the recent Chicago convention, and appeared to be a complete success. A lamp of this and smaller size will find an extensive field in the lighting of the home. In using this lamp for domestic lighting, however, considerable care must be used in the manner in which it is installed. The carbon lamp with clear glass bulb and without a diffusing shade is frequently placed directly in the line of vision. With the tungsten lamp, the intrinsic brilliancy of which is over twice that of the carbon lamp, the practice above described must be discontinued, or else the money saved in light bills will soon reach the pocket of the oculist. The tungsten lamp must be installed well above the line of vision, or else be so shaded that its intrinsic brilliancy will be largely reduced, and this fact should be thoroughly impressed upon all customers who are about to install this lamp. It is evident that such a course is desirable from the central station standpoint. By installing tungsten lamps in the manner described, the lessened efficiency of the installation, aside from the lamps, will offset in some measure the high efficiency of the light sources themselves.

The third class consists of those who are at the present time employing some other means for securing illumination than by electricity, in the interest of economy solely. (It is assumed that this is the only reason a person could have for using any other illuminant in preference to the electric light.) It is from this class that the lost revenue from classes one and two must be regained, and there is every reason to believe that not only will any possible loss be thus recovered, but that the electric lighting industry will experience a tremendous growth as a result of its being able to secure a class of customers which has heretofore been unobtainable.

In order to secure these possible customers described under class three above, this company has decided upon a campaign directed, at the start, against the gas arc. A proposition will be made to the users of this type of illuminant whereby the company will arrange for the wiring and for the installing of a tungsten fixture to replace the gas lamp. The customer will be allowed to select his own fixture from a number of designs covering a considerable range in price, and the installation will be made under the customer's direction. The total cost of the wiring, the fixture and the tungsten lamps will be assumed by the company, but this

[1] Abstract of a paper read before a meeting of the Contract and Inspection Department of the New York Edison Company, New York city, June 11.

amount will be repaid by the customer, without interest, in twelve consecutive monthly payments, which will be added to the monthly bills for current. After the final payment has been made the entire equipment, excepting the lamps, which are to be returned at the end of their life, will become the property of the customer. If the customer should vacate the premises before the last instalment is paid, or if the contract should be terminated before the final payment, it is understood that the installation may be transferred to the successor under a similar arrangement, to continue until all payments have been made. If such a transfer should be impossible, the original customer must pay the full amount necessary for a complete liquidation.

There are a vast number of gas arcs in use in this city at the present time, but the policy outlined above should result in their nearly complete elimination. A few figures comparing the cost of operation of a gas arc to that of a tungsten fixture, giving approximately equal illumination, may be of interest. The majority of gas arcs, particularly those installed in small stores, are in service on a rental basis. The Municipal Lighting Company has a large number of arcs so installed. Their charges are seventy cents a month for the four-mantle lamp and a dollar a month for the one having six mantles. These prices include maintenance, so, adding the cost of the gas consumed by the lamp, the total operating cost is secured. Some figures recently obtained under actual working conditions were as follows: Cost of gas consumed by a four-mantle lamp burning four hours a day (excluding Sundays) for one month, was $1.62; adding to this the rental charge of seventy cents makes a total monthly cost of $2.32. For equal illumination a tungsten fixture would be required having four forty-watt or possibly three sixty-watt lamps. Assuming the latter combination, with a life of 1,000 hours for the tungsten lamps and current at ten cents per kilowatt-hour, a total monthly cost of $2.35 would result. To this might be added an interest charge upon the cost of the equipment, which would reach its full value only at the end of the first year, when all payments had been made, and is really too insignificant to be included, as the total cost of the equipment, excluding lamps, will rarely exceed $15. Compare the above figures and then take into consideration the many advantages possessed by the tungsten lamp not shared by the gas arc, namely, the color of the light, which is nearly a pure white, as compared with the greenish-yellow color of the gas lamp; a comparative absence of heat, the presence of which makes the gas arc decidedly objectionable during the greater part of the year; and lastly, the fact that the atmosphere is not vitiated. It is stated that a four-mantle gas arc consumes as much oxygen as a dozen people, and the truth of this statement is evident to one who has entered a certain class of small stores on a winter's day. Even if the cost of a given amount of illumination is slightly greater with the tungsten lamp than with a gas arc—which is probably true in the case of certain inverted mantle arcs—the advantages enumerated above should outweigh any such slight difference in cost.

The use of the tungsten lamp for show-window lighting will be touched upon. The fundamental requirements for effective window lighting are: (1) That the sources of light be concealed from the eyes of the passerby, or, if this is impracticable, that they be surrounded by diffusing globes or shades, so that their intrinsic brilliancy will be largely reduced; (2) that a sufficient quantity of light be thrown upon the goods to be displayed so that the portion of this light which is reflected to the eyes of the observer will produce the desired effect, namely, a vivid visual perception of the goods which are on display.

A Single-Phase Locomotive for the Prussian State Railways.

A brief description is given in *Electrical Engineering* (London), for June 11, of the new single-phase locomotive which has been built for experiment on the single-phase line of the Prussian State Railways, at Oranienburg. The locomotive consists of two two-axle units coupled together. Three of the four motors are driven by single-phase motors of the Winter-Eichberg compensated repulsion type, and a fourth motor may be mounted on the remaining axle if found necessary. Each motor is rated at 350 horse-power on the one-hour-and-seventy-five-degrees-centigrade basis. With this load the speed of the motor is 450 revolutions a minute. Using forced draft, the continuous capacity of the motors is 250 horse-power, the speed then being 500 revolutions a minute. These motors are said to differ but little from the 350-horse-power motor experimented with two years ago. The latter weighed five and one-half tons, had six poles, and was designed for twenty-five cycles. The motors are geared to the locomotive axles with a ratio of 1 to 4.21, and the driving wheels have a diameter of 4.6 feet, so that the speed at the one-hour rating is seventeen and one-half miles an hour with a total draw-bar pull of 22,000 pounds. At the continuous output rating the speed is nineteen and one-half miles an hour with a draw-bar pull of 14,300 pounds. The maximum speed of the locomotive is thirty-five miles an hour. The total weight of the two units is fifty-nine and one-half tons. The locomotive is supplied with current at 6,000 volts, twenty-five cycles, by means of two bow collectors, one on each unit. The pressure on the wire is nine pounds, which is controlled by compressed air. The main transformer reduces the pressure from 6,000 to 1,000 volts. It is air-cooled by forced draft supplied from a fan driven by a thirty-horse-power Winter-Eichberg motor, which is started by means of a series choking-coil which is automatically short-circuited when a speed of 700 revolutions a minute is attained. The air for the transformers and motors is drawn through choke filters to free it from dust. Compressed air for the brakes, bow collectors and other devices is supplied from a compressor driven by a seven-horse-power motor which is automatically started when the pressure falls below six atmospheres. The main controller has four starting positions and four running positions, and a simplified controller for operating at the lowest voltage only is supplied for use in switching operations. By means of a choking-coil, the centre of which is connected to the motor lead and the ends to transformer tappings, the connections are changed from point to point without short-circuiting the transformer. The contactors controlling the connections are operated by current from the main transformer at a pressure of 300 volts.

American Street and Interurban Railway Association.

The annual convention of the American Street and Interurban Railway Association and the affiliated associations of the Accountants, Engineers, Claim Agents, Transportation and Traffic Managers, and Manufacturers, will be held at Atlantic City, N. J., on Monday, Tuesday, Wednesday, Thursday and Friday, October 12 to 16. The days upon which the different associations will hold their meetings have not been definitely decided upon, but these will be announced in the near future.

The exhibit of the Manufacturers' Association will be located on Young's "Million-Dollar" Pier, and it is expected that a display even more attractive than that of last year will be given.

THE RESISTANCE EQUIVALENT OF ELECTROMAGNETIC RADIATION FROM A LINEAR OSCILLATOR.

BY OSCAR C. ROOS.

In presenting this article the writer first wishes to call attention to one or two preliminary considerations which have given rise to some obscurity in the treatment of such problems as the wireless telegraph engineer is called upon to solve. It is then purposed to indicate the method of an engineering attack upon the problem of the number of watts expended in the ether as electromagnetic radiation with a given harmonic current at the base of the vertical used in wireless telegraphy. There follows the resulting solution of the equally important question of the current intensity at the base of the vertical with a given harmonic electromotive force.

On examination of several papers which have appeared to account for the radiation from a vertical, it becomes increasingly evident that a tendency exists to ignore the inherent differences in the physical behavior of Hertz oscillators and the large oscillators of the vertical, inverted "L," "T"-shaped and other types used as verticals in wireless telegraphy. Three serious consequences have immediately ensued to mar the accuracy of all analyses based on the assumed similarity: (1) Deductions made as to the resistance equivalent of radiation from hot-wire measurements have not led to consistent results when the frequency was changed, (2) reactances measured at the "driving point" of a vertical wire have not furnished consistent values of current, and (3) the expected resistance equivalents and the observed have not, in analyses hitherto presented, agreed within engineering limits of accuracy.

The subject of the linear oscillator as a whole is an extremely intricate one if a rigorous method of analysis (such as is given in MacDonald's "Electric Waves") is used. Abraham and Hack have given a treatment of the linear oscillator which, while elegant from a mathematical standpoint, is not as accurate in practice as MacDonald's, and whose artificial assumptions allow no simple conception of the dissipative agencies in action. These, however, are easily grasped from a study of the engineering theory of radiation developed by an American physicist and engineer, J. S. Stone, and presented before the International Electrical Congress at St. Louis in 1903 and subsequently republished in these columns (October 15, 1904). Although this theory has been before the technical and scientific world for more than three years, no practical application seems to have been made of it, as far as the writer is aware, in any phase of the wireless telegraph industry, except as undertaken by one or two personally interested mathematicians and members of his technical staff. Hence, as was to be expected, the errors mentioned above as the result of applying cumbersome analyses directly to the problem have crept into the work even of writers of some considerable authority on electrical matters.

Professor J. A. Fleming, author of "The Principles of Electric Wave Telegraphy," in a paper on the Poulsen arc and continuous electric oscillations, published in these columns on November 9, 1907, identifies himself with those who have fallen into the error of basing their work on the assumption that Hertz's treatment of the electric doublet shows it equivalent to a linear oscillator, and has, in addition, "grafted" on these assumptions a physical condition taken from MacDonald's analysis above referred to, which analysis is based on an entirely different treatment from that of Hertz. I shall not go into details as regards this forcible "hybridization" of formulæ; as in a future paper I expect to present MacDonald's results made practical for wireless telegraph engineers with the aid of Stone's engineering method.

In indicating a more accurate treatment of the problem of the resistance equivalent of radiation (a term first used by Stone) I must state that after all is said and done the acceptance of this theory is really based on facts rather than analysis, since no published analysis that is likely to be put to use for several years yet, is complete enough to take all the factors of the problem into consideration, especially that of the variability of the resistance equivalent of radiation with leakage, etc.

In Professor Fleming's article above mentioned there occurs a formula giving the power in watts of a Hertz oscillator vibrating at its fundamental

$$W = 40\,\pi^2 \frac{l^2}{\lambda^2} A^2$$

As an expression of the power of a Hertz oscillator or electric doublet the above is correct, since we may take the current to be practically uniform along the axis. When applied by Professor Fleming to a linear oscillator or wireless telegraph vertical, however, whose height is not negligible in comparison with the wave-length of the emitted radiation, it is seriously in error, since the current is not uniform along the axis, but is distributed according to a "cosine law" with a maximum at the base and nodes at the free ends of the vertical wire and its earth "image," if we assume uniform constants per unit length of the vertical.

In the summer of 1905 I was led, in the pursuit of a mathematical research on the inductance per unit length of a vertical, to a formula for the energy of radiation, whose accuracy has since been shown by the increased accuracy of predictions as to resistance of radiation; some have been verified, experimentally, by observers in a different field of electric wave engineering.

This practical engineering formula is a special case of a more general result, which includes all frequencies of vibration from zero to infinity, and to which I shall refer later on, but which in the present state of the art would not be called upon for accurate quantitative results.

Returning to Professor Fleming's article, we find the formula given by him would be correct for a wireless telegraph antenna if his l, or length of complete oscillator, were replaced by a smaller length l_H equal in value to the length of the equivalent Hertz oscillator acting at a distance. This quantity l_H is found by using Stone's method of decomposing the linear oscillator vibrating at its fundamental frequency into an infinite number of Hertz oscillators of length varying according to an inverse cosine law, between zero and the length of the vertical. This law follows from the general differential equations of the problem as solved for current, which in all cases varies as a circular function along the complete linear oscillator, and in the case of the fundamental frequency of vibration gives the cosine curve with antinode of current at the equatorial plane.

The linear oscillator may, accordingly, be looked upon, as regards its resultant field at a distance, the criterion of radiation by Poynting's theorem, as being composed of an infinite number of elementary Hertz oscillators, each of whose lengths is expressible by the formula $l_H = \frac{v}{n} \cos^{-1} \frac{nx}{v}$ and the average or effective length $l_{eH} =$

$$\frac{v}{n} \int_{-a}^{+a} \cos^{-1} \frac{nx}{v} \frac{dnx}{v}$$

where $$x < +a > -a$$

and $$\frac{na}{v} = \frac{\pi}{2}$$

In the above a is the length of vertical or air wire; $v = 3 \times 10^{10}$ centimetres per second, the velocity of light; n ($= 2\pi f$ where $f =$ frequency) is the "vectangular velocity" and is variously called "periodicity," "oscillation number," etc., which are misnomers; as it has the dimensions of an angular velocity and in fact is the angular velocity of the vector whose projection on a plane would show the harmonic time relations of the current in question.

The above quantity l_{eH} is the effective or average length of a Hertz oscillator giving the same field and energy flow at a distant point, as our linear oscillator. A physically more direct procedure is to decompose the linear oscillator into an infinite number of elementary current filaments of different charges, but equal lengths, in accordance with Hertz's own expressions. The results of the two methods are in this instance, however, identical.

In the multiple antennæ used by the Stone Telegraph and Telephone Company it has been found that the assumption that $l = \frac{\lambda}{2}$ at fundamental frequency, where $l = 2a$, or twice the height of the vertical and $\lambda =$ wave length emitted, is very approximately true. The uniformity of the vertical wire constants along its length is quite sufficiently accurate for engineering practice. Now, the effective length l_{eH} may be taken as $l_{eH} = \frac{2}{\pi} l$ when we have the fundamental vibration, and Professor Fleming's formula then becomes

$$W = 40\,\pi^2 \left(\frac{2}{\pi}\,l\right)^2 \frac{A^2}{\lambda^2} = 160\,\frac{l^2}{\lambda^2}\,A^2$$

for the complete linear oscillator where A is the maximum current, or $W = 40\,A^2$ watts.

The hot-wire ammeter, however, reads effective values, hence $W = 80\,A_e^2$ where $A_e =$ effective amperes for the complete oscillator and R^1, the "resistance equivalent of radiation," equals forty ohms for the air wire alone. This result has been the basis of regular engineering treatment of transmitting and receiving problems of all kinds since it was discovered and has been incorporated in patents now pending for radiotelegraphy, suitable constants being applied where the conditions are not those assumed in this case.

If we "hybridize" MacDonald's result with the above conditions by assuming for a vertical $l = \frac{\lambda}{2.5}$ and an approximately cosine law of current distribution along the vertical, we find that R^1 comes out as about twenty-five ohms instead of sixty-four, as given by Fleming.

Passing now to the more general method of viewing the problem, we will first take the region of frequencies below the fundamental, since most verticals in use are loaded with inductances. Such verticals can vibrate effectively, solely at frequencies below the fundamental on account of the increase of R^1 as the square of the frequency, although there are theoretically an infinite number of frequencies at definite periods apart in the frequency scale where such natural vibrations are possible. As we approach zero frequency the current distribution curve flattens until in the limit with zero frequency it approaches a straight line. This range of frequencies, while not as interesting from an analytical standpoint as that above the fundamental, is, however, the practical one for wireless telegraph

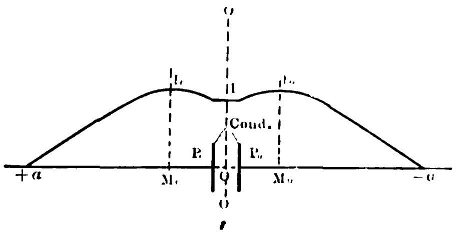

FIG. 1.—CURRENT DISTRIBUTION IN A LINEAR OSCILLATOR.

engineers in the present published state of the art. The formula covering it is

$$R^1 = 40\,csc^2\,k\,\frac{\pi}{2}\left(1 - \cos k\,\frac{\pi}{2}\right)^2 \text{ ohms}$$

where k is the fraction of the fundamental frequency at which the vertical is to vibrate, assuming unit current at base of vertical, and maximum current therefore as $csc\,\frac{na}{v} = csc\,k\,\frac{\pi}{2}$. This, of course, is a special case of the more general formula for R^1 covering all frequencies previously referred to.

For frequencies just above the fundamental we find by reference to Fig. 1 that the current distribution in a linear oscillator is equivalent to two complete systems of Hertz oscillators, which overlap by almost a quarter wave-length, and whose radiative tendencies may be considered absent where each passes through the equatorial plane; in other words, the current loop or antinode is shifted toward the free end of the wire and equals the current at the base multiplied by $csc\,\frac{na}{v}$ where a is the length of air wire in cm. $n =$ vectangular velocity

$v = 3 \times 10^{10}$ cm. per sec. = velocity of light.

To illustrate: In Fig. 1 we have a complete linear oscillator represented with the current distribution along its length due to a "forced" oscillation above the fundamental of the vertical, and having an inductive reactance requiring, therefore, a condenser c at the equatorial plane to neutralize said inductance reactance at the "driving points" P_1 and P_{11}.

Since the current throughout the condenser C is constant and equals I_o, the maximum current I_1, or I_{11}, is $I_0\,csc\,\frac{na}{v}$. This distribution of current holds within engineering limits in a helix of wire having uniformly distributed electrical constants, as in the case of the linear oscillator assumed. It is interesting to note a substantial empirical confirmation of the above theoretical distribution by C. J. Watson in the London *Electrician* of January 3, 1908. He found that with capacity added to a helix as an exciting connection for stationary waves that the node of pressure, and therefore current antinode, was shifted toward the open end of the vertical.

We may assume the effect of radiation at the driving point of the antenna or linear oscillator to be that of a purely non-inductive resistance. Assuming the distribution of current and potential to the left of the equatorial plane OO to be due to the image of the right-hand distribution. The distance of the antinodes of current from the equatorial plane $= \frac{ak}{1+k}$ where k is the fractional part of the fundamental frequency $\left(\text{say } \frac{1}{3}\right)$ by which the impressed frequency exceeds it, therefore $OM_1 = OM_{11} = \frac{a}{4}$ and $I_1 = I_{11} = I_0\,csc\,60°$. Fig. 1 incidentally shows the danger of drawing conclusions from hot-wire readings at the "base" of a linear oscillator vibrating above its natural or free period. If we re-draw Fig. 1 to show solely the variable part of the current distribution curve, as in Fig. 2, we have the basis of an engineering method of attack on the problem of all higher frequencies.

If we conceive a series of Hertz oscillators which have infinitesimal uniform currents and which vary in length from $+a$ to $-a$ (or $2a$) to $l_1\ o_1\ l_1$ at o_1 and zero at I_o, according to the inverse current distribution law, we shall obtain a mathematical "current sheet" if these elementary oscillators are laid side by side, as it were. It is readily seen that the dotted parts of the distribution curves on opposite sides of the equatorial plane contribute nothing to the radiation; in fact, the only questionable point of this analysis to be checked by practice is raised by the tacit assumption made that all the elementary Hertzian oscillators from $2a$ to zero have the same radiative power, when it is quite evident by an application of MacDonald's analysis that more radiation takes place from the outer halves of the oscillator than the inner: as a corrective tendency, however, the relatively stronger equatorial fields seem to restore the uniformity of action between the above parts. We may now represent Fig. 2 by a series of Hertz oscillators as in Fig. 3. Four elementary oscillators are shown, $a_1\ a_2$ and $a_3\ a_4$ are treated as one oscillator of length $a_1\ a_2 + a_3\ a_4 = 2a_1\ a_2$, $b_1\ b_2 + b_2\ b_3 = 2\ b_1\ b_2$ and $c_1\ c_2 + c_2\ c_3 = 2\ c_1\ c_2$, etc.; hence the averaging is simply a problem of quadrature applied to the current sheet "area," $+ a\ I_1\ I_0\ I_{11} - a + a$.

The fractional overlapping of the central "current distribution sheets" becomes less and less as we pass to frequencies above the fundamental and is zero at the octave—an impossible case, however, since the reactance at the driving point is infinite for the octave and for all even harmonics including zero frequency, according to Stone's formula (which has been amply verified by engineering results).

$$Z = -L_1\, v\, ctn\, \frac{na}{v}$$

where Z = reactance L_1 = inductance per cm. (c. g. s.) $2\,a$ = length of complete linear oscillator.

Proceeding to frequencies above the octave, we have a supplementary overlapping of the middle "current sheet" units, and on each side of this region two complete "current sheets" in opposite phases from the joined middle sheets, and each of length $= \frac{\lambda}{2}$.

To illustrate: In Fig. 4 we have a current distribution curve giving us a sheet of elementary Hertz oscillators for a frequency (say) two and one-third times that at the fundamental —our frequency unit in this analysis— *i. e.*, above the octave. Since for the octave $\frac{na}{v} = 2\left(\frac{\pi}{2}\right)$, for this frequency $\frac{na}{v} = \frac{7}{3}\cdot\left(\frac{\pi}{2}\right)$ radians. However, as the maximum current at the octave with unity current at equatorial plane is $csc\ \pi = \infty$, we have a discontinuity to take account of in our formula. It will be noticed that since our equivalent length Hertzian oscillator is derived by calculating the average "height" of the Hertzian oscillators in the oscillator current-sheet, by taking the "area" of same, we can ignore

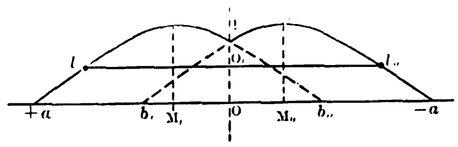

FIG. 2.—VARIABLE PART OF THE CURRENT DISTRIBUTION CURVE OF A LINEAR OSCILLATOR.

the symmetrical image of either side in obtaining this result and hence only one set of oscillators is indicated in Fig. 4.

In Fig. 5 we have the current distribution curve giving the Hertzian oscillator "sheet" or "area" for a frequency about 3.5 times fundamental frequency. In

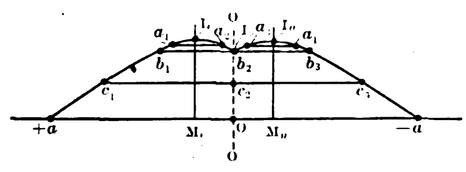

FIG. 3.—LINEAR OSCILLATOR REPRESENTED AS A SERIES OF HERTZ OSCILLATORS.

both Figs. 4 and 5 we notice a partial or "basal sheet" and a complete "sheet," the latter corresponding to a complete linear oscillator of length equal to length of "sheet base" $C_2\ C_3$. This linear oscillator is, of course, equivalent to a radiation resistance of eighty ohms, since its current distribution is sinusoidal and it may therefore be considered to be a separate added linear oscillator vibrating at its fundamental. By taking the "area" of the basal segment oc_1I_0 and getting its

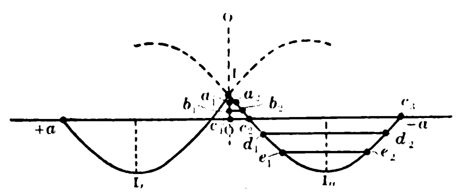

FIG. 4.—CURRENT DISTRIBUTION CURVE FOR A SHEET OF HERTZ OSCILLATORS.

ratio to the half area of the above complete added "oscillator-sheet," we obtain a ratio which gives us the "effective length" l_{eH} of the Hertzian oscillator corresponding to the above basal segment: this ratio, squared and multiplied by forty ohms, gives us the resistance equivalent of the basal sheet to be added to the complete or eighty-ohm "sheet." Thus the problem for all higher frequencies resolves itself into the determination of the above "basal area" effect in any case and the addition to it of a number of equal linear oscillators vibrating at their common fundamental.

We have accordingly:

Below the fundamental

$$\frac{na}{v} = k\,\frac{\pi}{2} \text{ and } R^1 = 40\ csc^2\,\frac{na}{v}\left(1 - \cos k\,\frac{\pi}{2}\right)^2 \qquad (1)$$

Between fundamental and octave

$$\frac{na}{v} = (1 + k)\,\frac{\pi}{2} \text{ and } R^1 = 40\ csc^2\,\frac{na}{v}\left(1 + \sin k\,\frac{\pi}{2}\right)^2 \qquad (2)$$

Between octave and first harmonic

$$\frac{na}{v} = (1 + k)\,\frac{\pi}{2} \text{ and } R^1 = 40\ csc^2\,\frac{na}{v}\left[\left(1 - \cos k\,\frac{\pi}{2}\right)^2 + 80\right] \qquad (3)$$

Between first harmonic and double octave

$$\frac{na}{v} = (3 + k)\,\frac{\pi}{2} \text{ and } R^1 = 40\ csc^2\,\frac{na}{v}\left[\left(1 + \sin k\,\frac{\pi}{2}\right)^2 + 80\right] \qquad (4)$$

The general formula becomes by induction,

$$R^1 = \frac{40}{\sin^2\frac{na}{v}}\cdot\left[\left(1 - \left\{\sin m\,\frac{\pi}{2} + \cos m\,\frac{\pi}{2}\right\}\cos\frac{na}{v}\right)^2 + m - \sin^2 m\,\frac{\pi}{2}\right] \qquad (5)$$

where $\frac{na}{v} = \left(m + k\right)\frac{\pi}{2}$, m being an integer and k a fraction.

The locus of R^1 as a function of the fundamental vibration as a frequency unit is roughly shown in Fig. 6.

For all even harmonics we are confronted with the very significant limitation of a theoretically infinite value for R^1 considered as a resistance operating at the driving point or base of the vertical. The physical reason for this becomes clear if we recollect, (1) that every linear uniform current element contained in the "oscillator sheet," being as regards radiation a separate elementary Hertz doublet of given length, offers an elementary dissipative (or radiative) resistance, according to the strength of its field at a distance, and (2) that the filaments which may be considered to end on the "base" or earthed part of the fictitious "current sheet," are, when the limiting cases of the even fundamental frequencies are approached, but a small and even vanishing percentage of the total sum or "area" of the current filaments composing said "sheet"; hence the rise of R^1 with the increase in the ratio of maximum current to basal current of antenna. It is well to remember that since the reactance and

R^1 of the linear oscillator are assumed, of course, in series, that the high reactances, approaching infinity at the even multiple harmonics, are, in addition to the reactance of the vertical *per se*, a separate means of limiting the current at the base.

In the above treatment it has been tacitly assumed that the series of synchronously vibrating segments on a vertical, under the conditions for stationary waves permits practically uniform maximum amplitudes of current in each segment, and that the radiation from any segment, according to Hack's amplification of Abraham's work on the linear oscillator, does not seriously modify the radiation from any other, and thirdly, that the field at a distance, due to a uniform current filament, is proportional to length of said linear elementary current. When mutual influences between current "segments" are appreciable they can be replaced by equivalent reactances and resistances, after attack by a modification of Heaviside's operational methods of analysis for this class of problems, and Stone's engineering treatment may then be applied to get the new form of R^1. However, the complexity of the results is not always compensated for by the gain in accuracy.

$= IR^1$. Therefore the vector sum or total drop gives us

$$I^2R^2 + I^2X = E^2$$

which gives us a cubic for I in the known quantities R^1, X and E.

In conclusion it may be stated that, as a matter of fact, the preceding general formula for R^1 has been amply verified both at and below the fundamental frequency by using substitution experimental methods of tuning to the vertical and

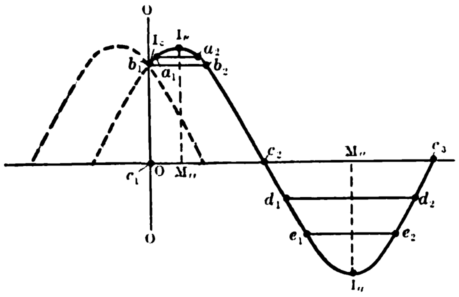

FIG. 5.—CURRENT DISTRIBUTION CURVE FOR A SHEET OF HERTZ OSCILLATORS FOR A DIFFERENT FREQUENCY.

thus reproducing the "contained R^1," *e. g.*, it is common practice to find at a frequency approximately one-half that of the fundamental a substitution value for R^1 of nine to ten ohms as required by this analysis, and not sixteen ohms, according to Fleming's formula. We have in the field of wireless telephone experiments further external evidence to corroborate the above analysis, these experiments indicating a value for R^1 of nine ohms at approximately the half fundamental frequency. These are cases taken at random from many to illustrate the importance of engineering instead of rule-of-thumb in wireless telegraphy—a field which already bids fair, by the use of precision methods aided by analysis, to outrank in accuracy of performance prediction some of the older branches of electrical engineering.

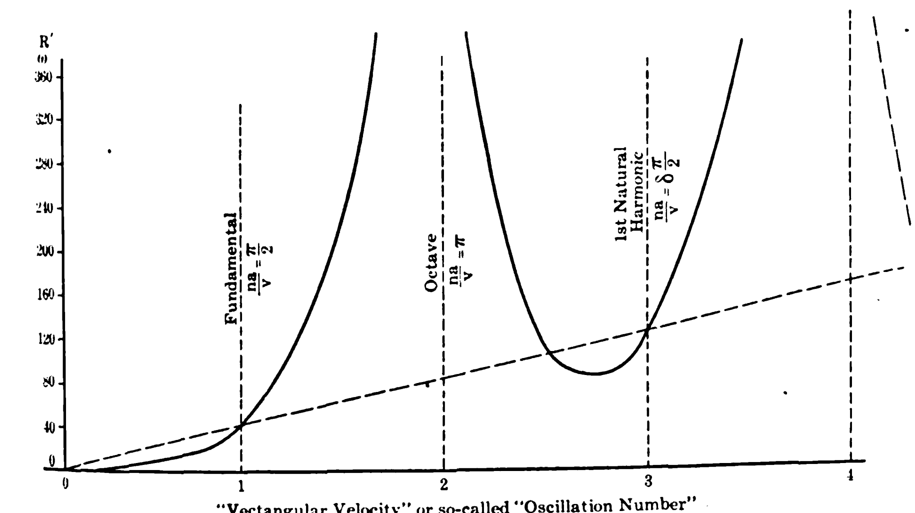

FIG. 6.—ROUGHLY DRAWN GRAPH OF FUNCTION R, "THE RESISTANCE EQUIVALENT OF RADIATION" AT DIFFERENT FREQUENCIES.

The final problem of the actual basal effective current I in a linear oscillator with an electromotive force E may be attacked in the usual manner of alternating-current problems as follows:

We know that the reactance "drop" to be accounted for in the vertical at the driving point is IX where $X = -L_1 \, v \, \frac{d}{dn} \frac{na}{v}$ and the resistance "drop"

BOOK REVIEWS.

"Die Elecktrizitätswerkbetriebe in Lichte der Statistik." Fritz Hoppe. Leipzig. Johann Ambrosius Barth. Cloth. 325 pages. 116 curve sheets and 197 tables. 7½ inches by 11 inches. Price, paper bound, 12 marks; cloth, 13 marks 20 pfgs.

This is the second edition of a similar treatise on statistics of power-plant operation, to which much material has been added, thus bringing it up to date. The book is divided into nine chapters and one appendix. The first chapter covers the development of electric power plants in Germany, discussing the number of plants, capacity of same, the system of power distribution employed, etc. Chapter ii, besides other material, gives the power consumption per section of the country, per inhabitant and the cost of same. Chapters iii, iv and v describe the kind of plant, *viz.*, steam, hydraulic or gas, and the type of machinery installed in each case. In these chapters the actual cost of operation is treated in detail. Chapter vi discusses the financial end of power-plant design and construction. Chapter vii discusses the rates to consumers, *viz.*, flat, maximum and minimum demand, sliding scale, etc. Chapter viii gives prices paid by railroads and factories, and the generating cost and the selling price. The last chapter treats of other Continental power plants as well as Great Britain and South Africa. The appendix gives different systems of bookkeeping used in power-plant operation.

It is evident that the compiling of the data mentioned, which are a fractional part of the whole, is tedious work. To facilitate matters, an exhaustive index is appended. The book is of great value to consulting and operating engineers and capitalists, particularly those of European countries.

"How to Become a Motorman." Second Edition. V. B. Livermore and J. R. Williams. New York. D. Van Nostrand Company. Cloth. 248 pages. Illustrated. 5 by 6½ inches. Furnished by the ELECTRICAL REVIEW for $1.

This is intended to be a thoroughly practical book for the motorman. The fundamental principles of the electric motor are briefly explained and then the different sizes and appliances are taken up separately, each being described with much detail, the methods of operation explained at length, and wire diagrams being given. All the systems of car and train control in use in this country are explained. The last portion of the book is devoted to study of air-brake systems for electric cars, the controlling apparatus being explained fully. The final chapter contains general rules for the guidance of motormen and conductors.

THE SMALL STATION AND ITS ECONOMICAL OPERATION.[1]

BY J. I. WHITTLESEY AND PAUL SPENCER.

The manager of the small plant generally has to be his own designing as well as his own operating engineer. He seldom, if ever, can afford to call in a consulting engineer to guide him in his work. There is undoubtedly a tendency in electrical engineering as in all other matters to follow the prevailing fad, and many small plants throughout the country have, in order to keep in the fashion, adopted complicated and costly improvements entirely unsuited to their conditions.

It should be a cardinal principle in all station design that no piece of apparatus or any appliance should be installed that can not justify itself, not only on the basis of the economy promised by the manufacturer of the appliance, but also on the most conservative basis; full consideration being given to its first cost, its depreciation, the additional labor that its use may entail, and the question of extensive repairs, which can be made in a small plant only with difficulty.

Every additional piece of apparatus in the station is an additional source of possible trouble and cost. It will be found that many of the so-called labor-saving devices and other promised adjuncts to economy are applicable only to stations of comparatively large size and have no place in such stations as this paper is considering.

The simple design is always the safer one to adopt for the manager of a small station. If he will be content with following out the lines suggested in this paper for the design of his plant, he will save himself a great deal of time and useless worry in attempting to decide the question of economy to be obtained from the refinements recommended, and he will certainly not run the risk of making the serious and costly mistakes into which some managers have been drawn.

While it is important that the design of the station should be simple, simplicity of design does not mean lack of design, and it is probably of even more importance in the cost of the small plant than of the large plant that it should be arranged at the start so that it can be developed along definite lines.

Every station manager should forecast for himself the development of his load so that he may have some idea of the conditions it will be necessary for him to meet from year to year in the future. It is an excellent plan to assume some reasonable percentage of growth in order to ascertain what point at the end of a period, say ten years, the expected load on the station may reach, and to draw up some tentative plan, at least, to meet such an estimated load, working backward on the problem to see when the additional apparatus will have to be installed, in order that the capacity may keep pace with the growing load.

With such a more or less definite plan in mind the extensions can be made from year to year in the most economical manner, so far as first cost is required, and with a uniformity in the design and size of apparatus that will help toward efficient operation. Such a definite plan will also enable the station manager to avoid the costly rearrangement of buildings and of apparatus, which have so frequently been necessary in the past and have swelled so much the station's scrap pile.

Assuming that a new station is to be built, certain broad features of the design can be laid down as essential.

First of all, the plant will undoubtedly supply alternating-current service, generating and distributing at 2,300 volts, multiphase, sixty cycles. One class of apparatus only should be installed, and the entire business, whether commercial lighting, street lighting or power, should be supplied at sixty cycles, alternating current.

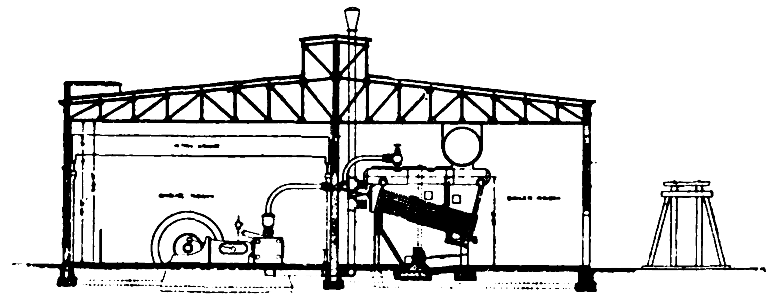

FIG. 1.—SECTIONAL VIEW OF PROPOSED PLANT.

In choosing a site one should be selected that will have railroad facilities and, if possible, a supply for condensing water, as a condensing plant will be desirable when the load has grown to a certain point. The site should be of suitable shape and sufficiently large to provide ample facilities for future extensions.

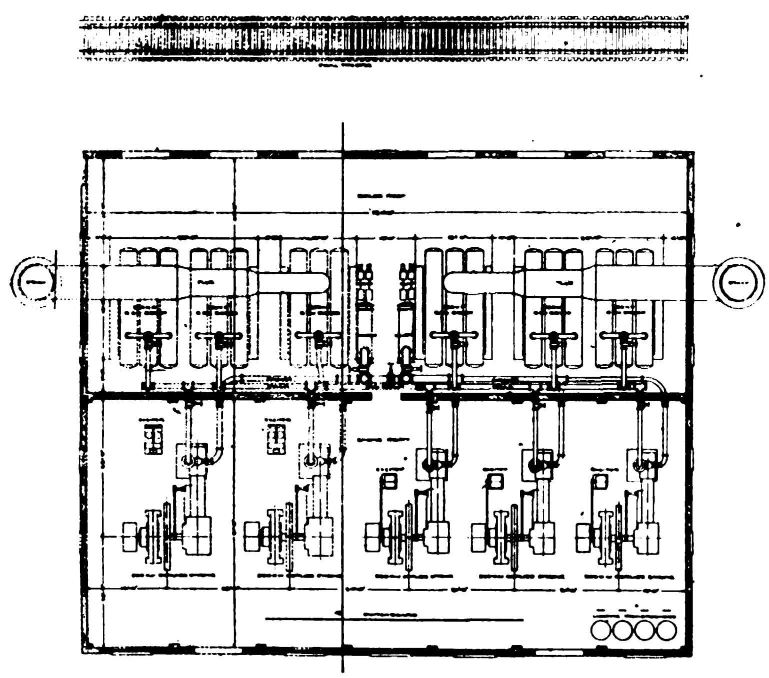

FIG. 2.—PLAN VIEW OF PROPOSED PLANT.

It is also desirable that there should be room on this property for stable or store room, as economy in the entire operation of the company will be gained by having all such buildings located at one point. The site chosen should, if it can be obtained without sacrificing other advantages, be close to the centre of the town. In this way distribution will become simpler and the plant itself and other

[1] Abstract of a paper read before the National Electric Light Association, Chicago, Ill., May 23.

buildings will be more convenient for the employés and more directly under the supervision of the manager.

The design of the engine and boiler room should, of course, provide for indefinite extension. This means a parallel engine and boiler room.

The station itself should be fireproof, with brick walls, concrete floors and steel roof. A crane in the engine room is desirable but not necessary. The gutters and flashings should be of copper, and window frames, doors, hardware and other details should be substantial, so as to keep down the cost of building repairs.

The stack should be of brick, as steel stacks will in every case be found to be the most expensive in the end, both because they require a constant maintenance charge for painting and because sooner or later they must be replaced.

For a small load, say under 1,000 horsepower, we believe that a simple non-condensing station will show the greatest total economy, including not only economy in operation but interest and depreciation on the apparatus installed.

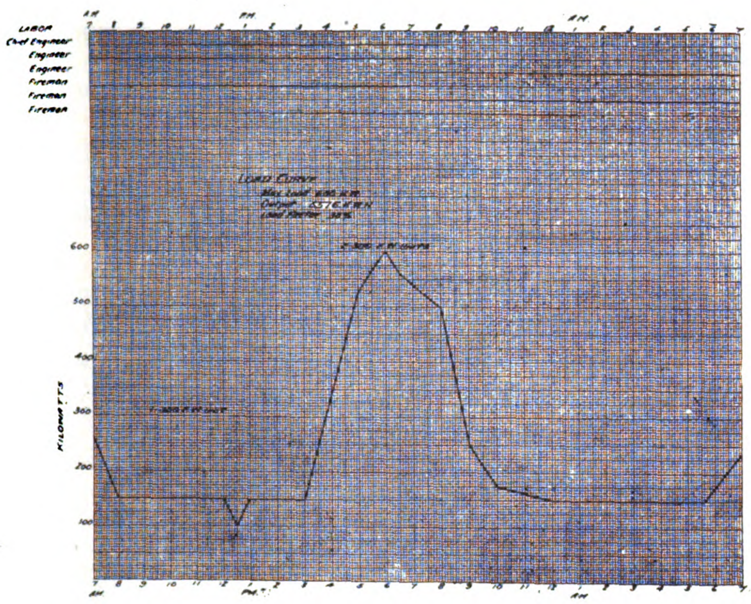

Fig. 3.—Assumed Load Curve for an Average Maximum Day.

Consideration should also be given to the fact that in such a station, with only a small number of men employed, it is impossible to obtain, for the wages paid, very expert men and that, therefore, the best results will be obtained by keeping all the apparatus as simple as possible.

The generating unit should be direct-connected with engines, preferably of the Corliss type, of moderate speed. The boilers may either be fire-tube or water-tube, but should be hand-fired, with no elaborate machinery for handling fuel or ashes. The station auxiliaries should be reduced to a minimum.

The exciters will be belt-driven from the engines, and the only steam auxiliaries will be a feed-water heater and the boiler-feed pumps.

The switchboard design should provide for exciter panels, located in the middle of the board, with sufficient space left for all future extensions. A Tirrill regulator will be found most desirable. Its first cost is low, and in a station where labor is to be reduced to a minimum it will be necessary to have such a voltage regulation if good service is to be given. With the exciter panels located in the middle of the switchboard, the generator panels will extend as may be needed on one end and the feeder panels on the other. All connections from the generators to the switchboard should be carried in cable under the floor, and the outgoing feeders should also be carried under the floor to a wire tower at the corner of the building.

TABLE I.

TABLE OF LOADS AND APPARATUS.

Year.	Maximum Load.	Kw-Hour Output.	Units.	Total Capacity Kilowatts.	Available Capacity[1] Kilowatts.
1908	600	1,320,000	3 300-kw	900	750
1909	660	1,452,000	....	900	750
1910	726	1,597,200	....	900	750
1911	799	1,757,800	1 500-kw	1,400	1,125
1912	879	1,933,800	....	1,400	1,125
1913	967	2,127,400	....	1,400	1,125
1914	1,064	2,340,800	....	1,400	1,125
1915	1,170	2,574,000	....	1,400	1,125
1916	1,287	2,831,400	1 500-kw	1,900	1,750
1917	1,416	3,115,200	....	1,900	1,750
1918	1,558	3,426,700	....	1,900	1,750

Note—Yearly growth, 10 per cent. Output, 2,200 kilowatt-hours per maximum demand.

[1] Available capacity is largest unit down with 25 per cent overload on remaining apparatus.

Fuel should be delivered to the plant on a railroad siding extending the length of the boiler room and parallel to it. If possible a trestle should be installed, so as to provide headroom for dumping the coal from the cars, which can be stored under the trestle and wheeled to the boiler room as needed.

A general plan of the station embodying the above general ideas is shown in Fig. 1 and Fig. 2.

It will be noted upon examination of these drawings that the building suggested is extremely simple in design, and contains no basement, either under engine or boiler room. The steam piping is overhead with the exception of the free exhaust lines from the engines, and the arrangement is such as to give the shortest possible length of connections from boiler to engines.

While an ash hopper and basement under the boilers keeps the boiler room clean and enables more rapid and easier cleaning of fires, it increases the cost of getting out ashes and gives additional space to be kept clean. The additional cost is practically prohibitive.

The solid portion of the drawing indicates the building as it would be constructed for immediate needs: namely, a maximum load of 600 kilowatts, containing three 300-kilowatt units. The future extension to take care of the growth in load for ten years is indicated by dotted lines.

It is assumed that this station is to be built to meet a present maximum load of 600 kilowatts and that this load will be increased at the rate of ten per cent per annum compounded, and that the load-factor will be equivalent to 2,200 hours per year for each kilowatt of the maximum demand. This station can be built at a cost of from $125 to $150 per kilowatt.

Table I shows the growth in maximum load and output, and the station capacity installed to meet this load, for a period of ten years.

It will be noted that the original installation of three 300-kilowatt units would carry the load safely through three years with one unit out of service, at which time a 500-kilowatt would be installed, which would carry it five years; a second 500 would then have to be purchased, which would give an available capacity more than sufficient to carry the load through the remaining three years.

The complete plans of the station, including the dotted portion, show all of these units installed, with necessary boiler capacity. Such a station would have a total capacity, with the largest engine out of service, of 1,750 kilowatts, allowing a twenty-five-per cent overload on the units available for service.

There is also given in Fig. 3 an assumed load-curve for an average maximum day. On this sheet is also shown the capacity of generators running to meet the load, from which it will be seen that the 300-kilowatt unit will be running at only approximately half load during the light portions of the day and night. This would, of course, increase the fuel consumption during these hours over what it might be with a small unit of exactly the necessary size to meet the present load. It is expected, however, that in a very short time the day load would be increased so that the 300-kilowatt unit would be operating under more economical conditions. Should the territory in which the station is operating be of such character that it is impossible to obtain any great amount of day load, it would be desirable, perhaps, to install a somewhat smaller unit than that shown on the plan.

The operation of such a plant would require a minimum of labor and repairs. From experiences with similar plants, a total of six men is amply sufficient, including one chief engineer, two running engineers, two firemen and one fireroom helper. The hours which these men should work are shown in diagram on the load-curve sheet. By lapping the chief engineer and the helper, we should have four men in the plant over the peak of the load.

The overlap covers the afternoon hours, giving the chief engineer the best opportunity to overhaul apparatus and providing him with the necessary help to carry on his minor station repairs.

With the plant as described there will be practically no continuous repair work, with the exception of that required to keep the boilers in first-class condition. There will be but two single-cylinder slow-speed engines and one boiler-feed pump running at a time during the peak, and only one engine and one feed-pump for twenty hours of the day.

As this is a non-condensing plant, the steam pressure will be low, not over 120 pounds, which will make it possible, with a small amount of labor and attention, to keep the piping, valves, packings and so forth, in perfect condition, so that there should be no excuse for their not being maintained always at initial efficiency, even with the limited station force employed. When the engineer of a station is relieved of the care and annoyance ordinarily caused by condensing apparatus, mechanical stokers, forced draft and other complications, his whole attention may be given to maintaining the efficiency of his boilers and engines and seeing that they are operated to the best advantage under the load conditions.

The following particular points are brought up as essential to the economical operation of the station:

In the engine room it will be important for the chief engineer to see that the capacity in apparatus running follows closely the load curve. All units should be run at their highest possible point of efficiency. It is always desirable to run them overloaded rather than underloaded, and the engineer should not be afraid of carrying his units up to their full overload point.

The chief engineer should certainly have an indicator and take frequent cards so that he may know at all times the condition of his valves and cylinders and remedy any defects that may show up.

But it is in the boiler room that the greatest possibility lies of wasting or saving fuel and improving the station economy. No positive rules for firing can be laid down in general, on account of the differences found between fuels, and also on account of the various methods of firing adopted by different men, which if properly carried out may result equally well.

The cutting in and out of boilers and banking of fires must be watched as closely as the running of the engine room to make the boiler capacity meet the loads most economically. With most boilers of good design it is found more economical to overload them twenty-five per cent above builder's rating and in order to carry a short peak to go to fifty per cent or more rather than cut in an additional boiler. The slight falling off in efficiency of a boiler at these high ratings does not consume as much fuel as that required to keep one boiler banked, which can only be used for a few hours a day.

With a non-condensing plant there is no difficulty in getting hot feed-water always above 200 degrees, so that this point will not trouble the engineer.

The combined boiler efficiency, including the grate and heating surface, can be kept up to the highest point only by constant attention to the condition of the boiler setting and the tubes. Draft gauges and thermometers, which cost but little and are very simple to use, will give the engineer exact information with regard to the condition of the boiler and help the firemen to get the best out of the boiler and the coal. A thermometer should be installed on the feed line into the boiler and draft gauges on uptakes and immediately over the fire. A high-reading thermometer for getting flue gases should be used by the engineer occasionally to tell him the temperature of his flue gases, which will be a guide on the efficiency of the boiler. Periodical readings of the draft at different points through the boiler should be made to determine the loss of draft and see if the air leaks are excessive.

One great source of loss of boiler efficiency is the bad condition of boiler setting, cracks around drums and other points in the setting which admit cold air, decreasing the draft and lowering the temperature. Most plants have an excess draft available from the stack, so that even with a very bad condition in this respect ample draft is still obtainable for burning the coal as fast as is required. This results in a continuous loss unknown to the engineer, unless investigation with draft gauge or by torches is made, as suggested.

Every one is perfectly familiar with the necessity of keeping the boiler clean, both inside and out, to maintain its efficiency. The frequency of such cleaning will depend entirely upon the quality of fuel and water used. An increase of ten per cent in boiler efficiency can easily be made, even where conditions are not very bad, by repairing, setting and cleaning boilers.

An automatic damper regulator is essential, especially in a small plant where natural draft is used.

It is hardly practicable in a small plant for the engineer to make elaborate tests, flue-gas analyses, engine-efficiency or evaporation tests, but the total running results of the plant can be kept very accurately by a proper method of records, and it is very essential for the chief himself to keep such records or station log. He is not responsible for two factors greatly affecting his cost: namely, the nature of the load on the plant and the fuel furnished him. He can, however, by keeping accurate records, furnish the management with the information necessary for them to determine whether or not the fuel purchased is the best for the price and how the cost of production can be decreased by improving the load-factor. No scientific test is as good as a comparative run of several months under similar conditions.

In many plants of this size the output and the shape of the load curve are very similar from day to day and from month to month, so that, by obtaining the amount of coal burned and the output, a very accurate comparison can be made with different fuels, methods of firing and handling of the units.

It is essential, then, for the economical operation of a small plant that integrating wattmeters be installed on each generator and the daily output kept on the log sheet. The indicating instruments should also be read at sufficiently frequent intervals to enable a daily load curve to be plotted. Every pound of coal and ash should be weighed and the record turned in for each shift or period of load.

The engineer will have his pay-rolls and bills for material, so that with a very small amount of bookkeeping he can get the actual cost of labor, fuel, oil and waste, repairs to buildings, repairs to engines, repairs to boilers and repairs to electrical apparatus.

It is hardly possible in such a plant to subdivide the labor, as the ordinary repair work and maintenance of apparatus is done by the regular station help, part of whose time is also put into operating. Any extraordinary repairs requiring outside help or machine work will be entered up separately.

The engineer of the plant should not hesitate to try experiments in operating, provided, of course, the service is not endangered; such as different hours of cutting in and out boilers, overloading and underloading boilers, cutting engines in and out on the load at different hours. But these experiments will be of no value unless they follow out a definite programme to its final results and unless records are kept accurately and analyzed intelligently to compare the results obtained. Conclusions are often jumped at in station operating which at sight seem apparently correct but upon analysis prove to be entirely wrong. Good records and a careful analysis are the only proofs that can be accepted.

In taking hold of an old plant which is not operating at good efficiency it is difficult sometimes to locate the trouble and correct it. It is, of course, necessary to first secure accurate records as already described. This, however, will only show the total pounds of coal per kilowatt-hour and will not tell where the losses are.

The easiest point to be attacked first is the engine economy, which can be very readily brought up to its highest possible point with the engines in use. The records will then show if any gain in efficiency has been made.

After having brought the engines up to their best efficiency for the type, the boilers should then be carefully inspected and cleaned up. Boilers that have been neglected will require heavy expenditures to bring them up to a good standard of efficiency. This, however, must be done if the manager is determined to get good results from his plant in the end. No patching or partial cleaning of a boiler should be made unless it is absolutely necessary at the time to keep them in operative condition. Thorough repairs only will pay, but they will pay well in fuel saved, as the records will show if they are properly kept.

The operating costs of such a plant are given in Table II. The figures are conservative for a new plant, well built along the design suggested, and have been bettered in actual experience. Two columns of cost are given: First for a station having a load of 600 kilowatts and an output of 1,320,000 kilowatt-hours per year, and the other for the same station with twice the output and additional capacity necessary.

The figures for labor and fuel will vary considerably in different localities and under different conditions of the labor and fuel markets.

TABLE II.

OPERATING COST.

	Present Output.		Double Output.	
Item.	Amount.	Per Kw-Hour.	Amount.	Per Kw-Hour.
Superintendent	$1,000	0.0757 cent	$1,000	0.0379 cent
Labor	5,040	0.3819 "	6,480	0.2454 "
Fuel	9,723	0.7366 "	19,446	0.7366 "
Water	634	0.0480 "	1,268	0.0480 "
Oil and waste	600	0.0454 "	800	0.0303 "
Miscellaneous supplies and expense	500	0.0378 "	600	0.0227 "
Repairs, buildings	100	0.0076 "	100	0.0038 "
Repairs, steam	700	0.0530 "	1,000	0.0379 "
Repairs, electrical	75	0.0057 "	100	0.0038 "
Total	$18,372	1.3917 cents	$30,794	1.1664 cents

NOTES—Coal based upon Pennsylvania bituminous at $3.00 per ton, 5.5 pounds per kilowatt-hour.

Water based upon cost at 10 cents per thousand gallons, 40 pounds per kilowatt-hour.

Superintendent's salary at $3,000, one-third charged to production.

Labor: Chief engineer at $1,200 per year.
Two engineers at $900 per year.
Two firemen at $720 per year.
One helper at $600 per year.

Electrical Action of Sodium.

Some additional information is given by C. E. S. Phillips in *Nature* (London), for June 11, regarding the power of sodium to dissipate electrical charges. This was referred to in the ELECTRICAL REVIEW for June 20. He now thinks that the greater or less effect due to different portions of the same rod was caused merely by inequalities in the temperature of the sections examined. By lowering the temperature so as to reduce the oxidation of the surface, a more complete diselectrification was produced. This result seemed at first sight to point to a cause other than chemical action. A slight current of air and even a soap film were sufficient to stop the discharging effect, also supporting the view that an electrified gas was emanating from the metal. A bright surface of potassium gave no appreciable discharging effect when cooled with a mixture of ice and salt. In all cases the surfaces could be seen in the dark to be glowing strongly. Further experiment has shown that no active gas can be driven from sodium by heat, and that the true explanation of the action lies in the positive electrification of the air surrounding the freshly cut surface. With warm sodium it is seen that the gold-leaf falls rapidly for a very short distance, while after cooling the action is more prolonged. It is clear, therefore, that the action in the first case, although violent, is so transient, owing to the whole surface being rapidly oxidized, as to appear of small amount. A far larger discharging action was obtained with reduced oxidation owing to the effect being more prolonged.

REVIEWS OF CURRENT ENGINEERING AND SCIENTIFIC LITERATURE

An Electrical Pendulum Without Mechanical Connections.

The precise measure of time is a problem presenting a number of difficulties, since the oscillation of a pendulum is affected by temperature variations, barometric changes, variations in the friction of the escapement, and changes in the viscosity of the oil used for lubricating the movement. It has been estimated that fifty per cent of the driving power is lost in friction of the movement, and the latter is affected greatly by atmospheric conditions. When electrical or magnetic means are employed for driving the pendulum, instead of gearing, irregularities in the contact device may affect the swinging of the pendulum. To avoid all of these disturbing actions a pendulum has been designed by C. Fery in which an impulse is imparted to the pendulum without it being necessary for the latter to come into contact with any other body. For this purpose a horseshoe magnet is attached to the lower part of the pendulum, one end of which, as the pendulum swings, enters a small solenoid which gives it the required impulse to keep a swing of constant amplitude. The use of a horseshoe magnet is advantageous, as it renders the pendulum astatic and makes the magnet more permanent and more effective. The current flowing through the small coil is made and reversed by means of two contacts attached to a supplemental pendulum having the same period as the master pendulum and kept in oscillation by means of a copper ring at its lower extremity into which one end of the horseshoe magnet enters at one end of the swing. The eddy currents thus set up in this ring first move it along with the magnet in one direction, closing the circuit through the actuating coil, so as to give the master pendulum a pull. When the latter reaches the end of its swing and starts back, it drags the supplementary pendulum with it, due to the eddy currents set up, reversing the current through the driving solenoid and thus imparting a push to the master pendulum. In this way there is no mechanical contact and all the influence exerted upon the pendulum can be brought under perfect control. The entire apparatus may be enclosed within a sealed case protected from atmospheric changes and maintained at a constant temperature. This is made easier by the fact that the pendulum may be started from a distance by passing a current through the driving coil.—*Translated and abstracted from L'Industrie Électrique (Paris), June 10.*

Electric Iron and Steel Furnaces.

In this concluding section of a study of electric iron and steel furnaces some of the latest induction furnaces constructed are described. The Kjellin furnace of the latest type has a magnetic core with three legs—two outside the circular annular crucible and one within. Furnaces of this type, with capacities of eight tons, are now being built. With the bulk of the charge the ohmic resistance decreases, while the self-induction increases, thus reducing the power-factor. To compensate for this the frequency of the current may be lowered. A 750-kilowatt furnace being constructed for the Volklingen works is to be fed with currents at 5,000 volts, five cycles, per second. The core length is eight and one-quarter feet in this case. Such low frequencies are not desirable, as they necessitate special generators. The Electro Metal Company, of Ludvika, Sweden, improves the power-factor by raising the bath resistance, which is accomplished by means of a bifilar trough, which follows the outlines of a figure U in a closed curve. A furnace for 5,000 volts, at fifteen cycles a second, is being installed in the Volklingen works, where the five-cycle furnace is in use. In the new furnace the trough is elliptic, having the general shape of the figure eight with the central bridge much broader than the outer limbs. Both cores of the transformer are thus surrounded by the trough, while the bridge portion affords a spacious hearth. The transformer primary is cooled by filtered air, and a secondary of a few turns, also air-cooled, is placed about each primary. The currents from the two secondaries are led to electrodes placed so that the circuit is completed through the bridge portion of the hearth, thus bringing the current density at that point up to what it is in the narrower sections. The greater part of the heating is, however, by means of induced currents. The whole furnace has a semi-cylindrical bottom to enable it to be rocked for pouring purposes. In lining the furnace hoops of iron are set in, which are utilized for heating and drying out the lining. In use this furnace is never completely emptied, about 1,600 pounds of steel being left in the hearth to keep it hot. A complete heat lasts from two to three hours. The power-factor of the furnace is said to be 0.87. The thermal efficiency is from fifty to eighty per cent. The furnace operates steadily, and the temperature is easily controlled by varying the applied voltage. Another type of induction furnace has been constructed by Schneider & Company, of Creusot, France, in which the desired high resistance of the bath is secured by contracting the hearth in two parts. This furnace consists of two chambers connected by L-shaped channels having relatively small cross-sections, each of which is spanned by a transformer core. The furnace is charged in the larger of the two chambers, about 1,000 pounds of molten iron being poured in first to act as conductor. It is mounted on three pedestals, two of which may be raised and lowered to cause the metal to flow through the channels. Usually, however, the difference in temperature is sufficient to maintain the circulation. In this furnace about three tons of steel can be refined in twenty-four hours, about 1,600 pounds being drawn off after each treatment. From 800 to 900 kilowatt-hours are said to be necessary to refine one ton of steel, and the efficiency is estimated at fifty-five per cent. If liquid charges were used entirely, the output of the furnace would be increased to fifteen tons. Although in the pure induction furnaces there is not supposed to be any electrolytic action, purification being due entirely to chemical action brought about by heat, the manner in which phosphorus and sulphur are removed suggests that the alternating current must have some additional action.—*Abstracted from Engineering (London), June 12.*

The Cadmium Cell at a Low Temperature.

Although a great deal of research work has been carried out on the cadmium cell, it is surprising, says Henry Tinsley, that more attention has not been given to its behavior with varying temperature, especially at low temperatures. A cold snap in last April enabled him to carry out some experiments on a batch of cadmium cells which he had made up according to the London National Physical Laboratory's specification. On completion these were found to be correct within three or four parts in 100,000 when compared with a standard cell which had been checked. During the cold spell the temperature of the room in which these cells had been placed fell as low as three degrees centigrade, when it was found that the cells of the batch showed a difference of 190 parts in 100,000 as compared with the standard, and were thus near two millivolts off. All of the cells showed good agreement among themselves. It was not thought that this variation was due to careless manipulation, otherwise greater variation among the thirty-six cells of the batch would have been expected, while this was found to be only ten parts in 100,000. A typical cell was taken from this batch and observations made upon it as the temperature of the room changed, readings being taken every half hour, and the test cell with a checked standard being placed in an oil bath. The lowest temperature observed was 3.2 degrees centigrade. As the temperature rose from this, the master cell showed a uniform decrease in potential from about 1.0199 volts at 3.2 degrees to 1.0192 at twenty-two degrees. The new cell taken from the batch, however, showed a potential of only 1.0181 at 3.2 degrees and the electromotive force rose rapidly with the temperature, being about 1.0195 at ten degrees, and crossed the check-cell curve at twelve degrees, the electromotive force then being 1.0196. The curve then turned over, reaching its maximum value at fifteen degrees, when the potential was 1.0197. At seventeen degrees the curve had become parallel to the check-cell curve and from there on apparently was a straight line, about 0.0002 volt above the line for the latter cell. From this curve it is seen that below fifteen degrees the test cell had a positive temperature coefficient and above this the coefficient had the normal sign. It seems evident from this that this change in the temperature coefficient can hardly be due to chemical effect, as there is no such alteration in the solubility of the cadmium-sulphate solution. Some other explanation must be sought. The new cells had been constructed with cadmium amalgam containing twelve and one-half per cent of cadmium. The amalgam in the check cell contained but ten per cent of cadmium, and it was noticed that the latter remained bright and liquid throughout the experiments, while the twelve and a half per cent amalgam apparently became solid and the surface took on a frosty or crystalline appearance. Above fifteen degrees the latter again appeared to be fluid and the surface was bright. Early experiments with the new cells showed that above fourteen degrees centigrade they are in excellent agreement with the master cell, not varying more than two or three parts in 100,000 from their mean. Mr. Tinsley suggests that this investigation seems to indicate, although it has not yet been proved, that the twelve and one-half per cent cadmium amalgam becomes solid at temperatures below about ten degrees centigrade, and thus departs from its two-phase system of cadmium and mercury. It is probable that a similar curve would be obtained for the ten per cent amalgam cell if the temperature were carried low enough. The twelve and one-half per cent amalgam cell is in favor in Germany, although F. E. Smith, of the National Physical Laboratory, has pointed out the necessity of paying attention to the percentage of the amount of cadmium used in preparing the amalgam.—*Abstracted from the Electrician (London), June 12.*

Electricity or Gas?—The Problem of the Small Consumer.

Many years ago electricity was known popularly in England as "the poor man's light," but progress in gas lighting brought this expression into disuse. Now the development of high-efficiency incandescent lamps has turned the tables so that electricity should be able to live up to its former title. This is the view taken by J. D. McKenzie, who analyzes the problem presented in the supplying of electricity to the small consumer. When electric lighting was but little used the supply company could pick and choose its clients, and it generally completely ignored the small consumer. This policy can not be followed to-day. The electricity supply company must find some means of supplying light to the small home if it is to extend its field. In all large cities, and in many small ones, there are tens of thousands of homes requiring a maximum installation of from three to ten lamps, with a maximum demand of from one to five lamps at a time. Although the individual consumption may be very small, the aggregate would make a wide difference in the output of the central station. These small consumers are to a great extent grouped together closely, so that the supplying of them is a comparatively easy matter. The objections to the use of electricity by the small consumer are: First, the high cost of installation, and, second, the cost of using the supply. In other words, it is said that electrical apparatus is too expensive to install and the price for electrical energy is prohibitive. The author does not accept this view, for although the present price of metallic filaments is high, they are fragile, the price must come down, and improvements will surely be made mechanically. These objections, however, do not obtain for low-voltage supply, and hence need not be considered in the plan which he suggests. Regarding the cost of installation, it is cheaper to run a gas pipe than to lay underground cables meeting all the requirements of the Board of Trade; but many of these rules are unnecessary and there is no reason why a simpler method should not be adopted in which some relaxation of rules and regulations could be secured. Although it may be cheaper to lay gas pipe than underground cables, this should not deter the electric company from putting in its wires if it can see a profit in so doing; and if an overhead distributing system be provided for groups of houses, the electrical connection will probably be cheaper than the gas pipes. Moreover, in the majority of cases, the supply cables are actually passing the poor men's houses, many times merely to supply a light, short load. In such cases a short run of cable would be all that is necessary. Another item in the cost of installation is that of the meter. The average meter in use to-day is too expensive for this purpose. What is needed is one costing about $5 for a five-ampere load. The cost of electrical energy is then considered. This is found to be 5.2 cents per kilowatt-hour delivered to the consumer, not including any profit. This could probably be sold at six cents a kilowatt-hour and pay well. The cost of electric service is compared with that of gas, and the author says that from recent figures which he has obtained the cost for similar periods and identical conditions was 71 to 100 in favor of electric lighting where the price of energy was six cents a kilowatt-hour and that of gas sixty-six cents a thousand cubic feet. At this ratio electricity might be sold for ten cents a kilowatt-hour, which would be equivalent to gas at seventy-eight cents a thousand feet. The scheme of distribution proposed is to use a working potential of 200 volts alternating and to install a balancing autotransformer for each group of eight houses. From each branch of the transformer a supply is taken off to each house, giving twenty-five volts there. For a low-potential system of this kind elaborate precautions for the safety of the users are not necessary, and a much cheaper and simpler method of utilization may be adopted.—*Abstracted from the Electrical Review (London), June 12.*

INDUSTRIAL SECTION

ILLUSTRATED DESCRIPTIONS OF NEW AND STANDARD ELECTRICAL AND MECHANICAL APPARATUS

The Westinghouse New Model Roney Mechanical Stoker.

One of the problems most prominently befôre engineers at the present time is that of obtaining large evaporative capacity with sustained efficiency and smokeless operation. This subject came up before the Smoke Convention held in Cleveland last week.

Owing to the extreme difficulty of getting firemen to stoke in the manner required to secure the desired results, it has been quite generally agreed upon by engineers that the mechanical stoker furnishes the simplest and the cheapest means of maintaining the conditions necessary for smokeless combustion, especially of long-flaming bituminous fuels. These conditions are especially difficult to realize, except by mechanical means, under the heavy demands encountered in the modern boiler plant—which often require steaming rates of fifty to 100 per cent above rating for long periods. The essential requirements for perfect smokeless combustion are:

(1) That the fuel be fed continuously to the furnace in small quantities in order that the volatile gases may be driven off at a uniform rate.

(2) That these volatile gases shall be mixed with sufficient air and maintained at a high temperature.

(3) A sufficient distance must be provided between the fuel bed and the heating surface of the boiler in order that the volatile gases will have time to be completely consumed before being chilled by contact with the comparatively cool surfaces of the boiler.

(4) A suitable grate with liberal air passages for consuming the fixed carbon remaining after the coking process.

(5) Some means of continuously agitating the fuel so as to bring all the particles of carbon into intimate contact with the air supply.

(6) From a mechanical standpoint the grate bar should have a large ratio of cooling to heating surface to permit higher rates of combustion, at the same time insuring a long life.

In addition to the above, to permit high rates of combustion with moderate draft pressures, the following are also necessary:

(7) An automatic means of agitating and advancing the fuel bed at the proper rate of combustion to suit the load carried.

(8) Adjustable area for admission of air through the grate, increasing with the rate of combustion, so as to avoid excessive pressure drop through the grates and the fuel bed.

These conditions have been carefully considered in the design of the improved stoker herein described, and the improvements embodied therein represent the gradual development from experience gained in the equipment of over a million and a quarter horse-power in boiler capacity. The following is a summary of the most important features of the New Model stoker later discussed in detail.

FEATURES OF WESTINGHOUSE NEW MODEL MECHANICAL STOKER.

(1) Number of complete grate bars reduced one-half.

(2) Interchangeable parts (tops, webs, guards and dumping grates).

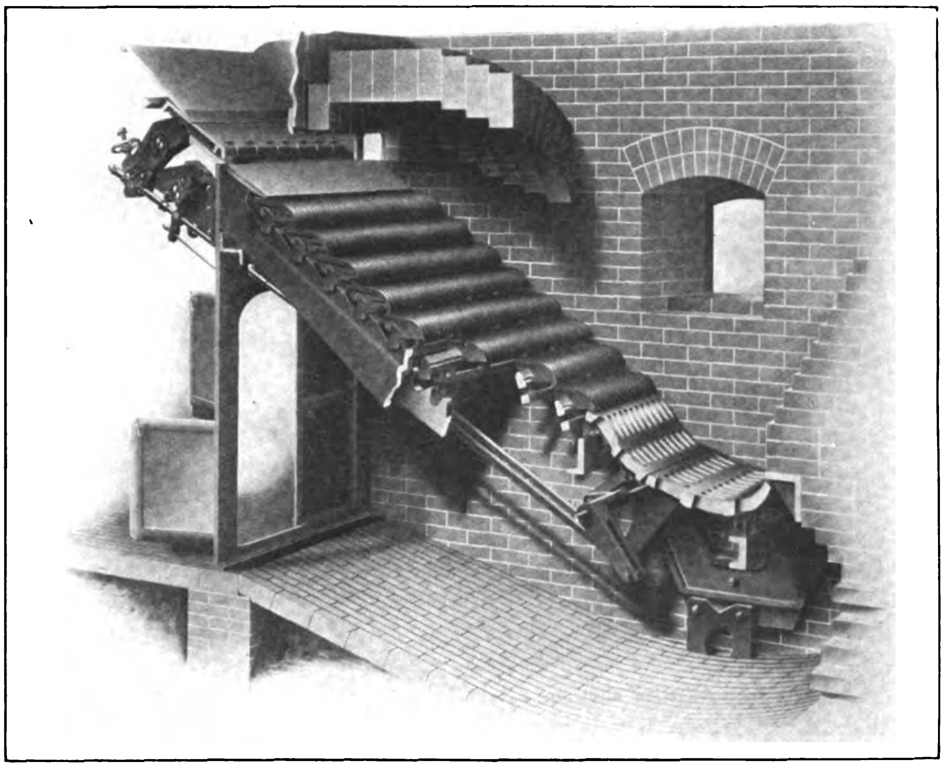
(3) Grate bars automatically centre themselves in side bearers by their own weight.

(4) No lost motion in grate movement due to wear, as grates return to inclined position by their own weight.

(5) Cooling surface of grate-bar tops 7.4 times the heating surface.

(6) Low cost of repairs, owing to small number of moving parts and long life of tops.

(7) Redistribution of grate-bar tops possible so as to equalize wear over all parts of the furnace.



SECTIONAL VIEW OF NEW MODEL WESTINGHOUSE RONEY MECHANICAL STOKER.

(8) No threaded bolts inside of furnace.

(9) Non-sifting tops provided for first four rows of upper grates.

(10) Guards and dumping grates interchangeable without disturbing side or centre bearers.

(11) Improved leverage for operating guard and dumping grate, minimizing labor of handling.

(12) Thrust of connecting rod on rocker arm, direct—not sidewise—thus avoiding twisting forces.

(13) One hand adjustment for both grate movements.

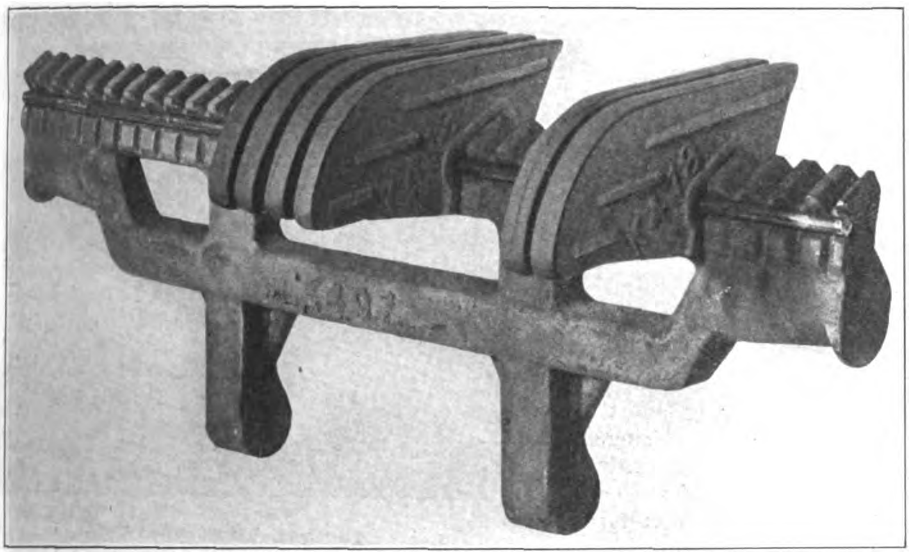
(14) Stop provided on each connecting rod to hold grates open for dislodging clinker.

(15) Improved air distribution over

arch, which cools the arch and heats the incoming air, thus preventing smoke.

(16) Baffles over arch direct air supply so as to obtain uniform air distribution over fire.

(17) Constant draft area through grate-bar tops practically two-thirds of total draft area.

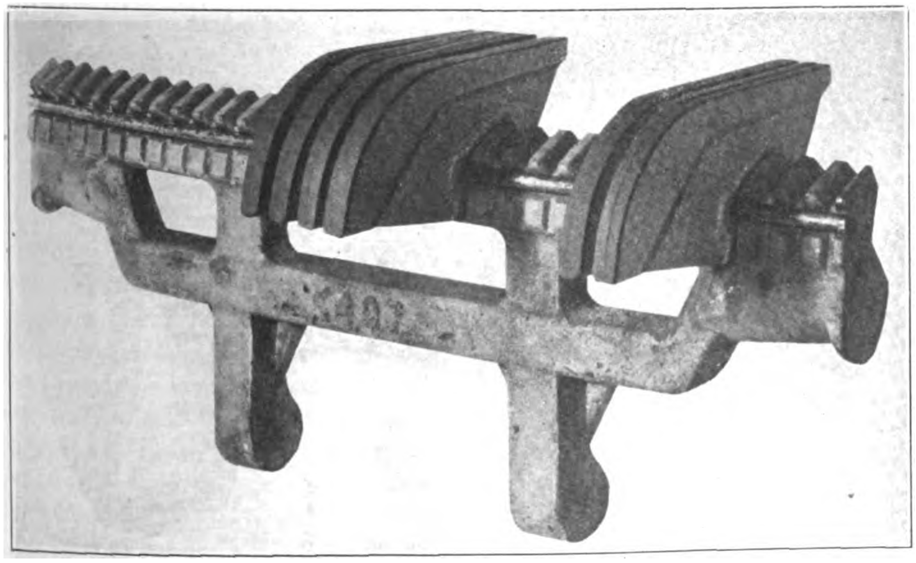


Upper Grate Bars, New Model Westinghouse Roney Mechanical Stoker.

(18) Moderate fluctuation in draft between limiting movements of grate bars.

GENERAL DESCRIPTION.

Reviewing briefly the general type, it will be seen that the coal is fed into a hopper extending across the boiler front, usually by gravity from an overhead bin. From this hopper the fuel is automatically



Lower Grate Bars, New Model Westinghouse Roney Mechanical Stoker.

supplied to the furnace by a reciprocating pusher operated from the rock shaft by an eccentric. The fuel descends through the throat of the arch on to the upper grate bars, where it is subjected to an intense heat radiated from the incandescent fire-brick arch spanning the upper portion of the furnace. This entirely cokes the fuel and drives off all the volatile gases, leaving the coke, or fixed carbon, which is then gradually worked down the inclined surface by the rocking motion of the grate bars, imparted to them from the eccentric on the rock shaft.

The oscillation of the grate bars not only works the fuel slowly down the furnace, but also keeps it constantly agitated, thus preventing to a large extent the formation of clinker, and bringing the fuel into intimate contact with the incoming air. After the solid combustibles have been totally consumed the remaining ash is discharged on to the dumping grate at the bottom of the furnace. The operations necessary to clean the fire are very simple. First the guard is raised to a position which prevents the fuel bed from sliding. Next, the dumping grate is dropped, permitting the ashes to fall into the ash pit.

From the foregoing brief description it will be evident that all the essential conditions necessary for high rates of combustion and smokeless operation have been fully realized, *viz.:*

(1) Fuel is fed to the furnace at a uniform rate, depending upon the load.

(2) Fuel is coked in the presence of a preheated air supply.

(3) Combustible is brought into intimate contact with the required quantity of air for complete combustion.

SECTIONAL GRATE BARS.

One of the most important features of the New Model Roney stoker is the sectional grate bar, or fire top, illustrated herewith. For the upper four grates a non-sifting type top is used, provided with abutting horizontal ledges to prevent the fine fuel from sifting through the bars and at the same time permit a free entrance of the air. As only the thin edge of the fire top is exposed to the direct heat of the fire, while both sides and the bottom edge are cooled by the incoming air, it is evident that these tops are well protected from overheating, thus insuring long life. As previously mentioned, for each square foot exposed to the fire, 7.4 square feet of surface is cooled by the air, giving 7.4 times the cooling effect of the flat-top grate bar.

As will be seen from the illustration, the grate proper consists of a number of thin plates set on edge in V-grooves. These hook over a trussed web and are held in place by a key-rod slipped in from the end. They are, therefore, easily removed. The webs have conical bearing surfaces at the end, which makes them self-centering in the side bearers and prevents any uneven wear. By lifting the webs out of the bearers and removing the key-rods, the tops may be redistributed if desired, so as to equalize the wear in various parts of the furnace.

Eight samples selected from different parts of the furnace below the arch line after seven months' wear showed a maximum and annual depreciation of about sixty-six per cent, indicating a minimum life of one and a half years.

An average annual depreciation of about seventeen per cent was shown by these eight samples, indicating a probable life of about six years if the bars are redistributed from time to time. In the upper part of the furnace, however, the wear was practically *nil.* It should be noted that the boiler from which the samples were taken was subjected to unusually severe conditions, having been operated above rating practically continuously and at times forced to 100 per cent above its rated capacity.

One of the principal advantages of the sectional grate-bar tops is that it reduces the amount of scrap when they have been sufficiently worn to be discarded. In this stoker, all internal parts are made interchangeable. No bolts are used and any part can be removed without disturbing the other.

GUARDS AND DUMPING GRATES.

The new type of guard prevents the fire from sliding into the ash pit when the dumping grate is operated. As the lower end of the guard is now raised, instead of cutting through the fire, as formerly, it not only makes it possible to dislodge from the fire all clinker formed at the bottom, but also provides an unobstructed descent for the ash and clinker separately. When dropped to its normal position it permits the lower edge of the fire to settle quietly without tendency to slide.

The new dumping grate is hinged about one-third forward, dumping both front and rear. Being nearly balanced, it is very easily operated. The upward motion of the dumping grate breaks up any clinker bridge tending to form between the grates and bridge wall. Both the dumping guard and grates rest in U-shaped trunions in the side bearers, the guard being simply hooked over the bearing rods. The latter can, therefore, be easily removed without dismantling any portion of the stoker.

ROCKER MOTION.

The rocking motion is transmitted to the grate bars by means of a connecting rod from the eccentric "agitator." As the grate-bar tops are unbalanced, they return to the inclined position by their own weight, and, therefore, only one feed adjustment is necessary, made by the sheath nut on the end of the connecting rod. As motion has to be transmitted to the connecting rod in one direction only by the agitator, a simple-looking device, or dog, is used for holding the grates open to permit rapid trimming of the fires.

AIR DISTRIBUTION.

As previously outlined, the most essential requirements for smokeless combustion are a gradual coking of the green fuel and an adequate supply of preheated air admitted above the coking bed. These conditions have received special attention in the design of the New Model Roney stoker. The air supply to effect the combustion of volatile hydrocarbons is admitted through two windgates located on either side of the stoker. It first passes to the rear of the fire-brick arch, extending across the front of the furnace, and is then directed by baffles to the crown of the arch, at which point it enters the front air spaces. From the latter it enters the furnace through the spaces between the stoker front and the first ring of arch brick. Passing the air over the furnace in this manner not only preheats the air, but assists materially in cooling the arch.

The fire-brick arch is of such extent and so designed that it completely cokes the green fuel and directs the gases downward over the hottest part of the fire, therefore permitting the volatile gases to be completely consumed before coming in contact with any of the boiler heating surfaces.

COMBUSTION.

With the grates open maximum width the effective admission area of the entire grate is 36.8 per cent of the project area of the furnace. At maximum opening—*i. e.*, in their lower position—the effective opening is 24.3; taking actual time of opening and closing, the average effective draft area of this type of stoker is 27.4 per cent of the total projected area, as compared with an average of 17.9 per cent with flat horizontal fire tops. This increased admission area makes it possible to maintain a higher rate of combustion. This has been very effectively brought out by a series of capacity tests conducted upon a 475-horse-power Babcock & Wilcox stoker-fired boiler at East Pittsburg. During these tests an output of over double rating, 224.7 per cent, was maintained for six hours, with but 0.42 inch furnace draft. This corresponds to a rate of combustion of forty-eight pounds per square foot per hour, with a very reasonable over-all efficiency of 63.5 per cent at this load. A test of twenty-five per cent above rating was maintained for six hours with 0.18 inch draft, with seventy-four per cent efficiency and twenty-three pounds of coal per square foot of grate per hour. The fact that the boiler and grate passed through this severe test without damage, while the brick setting was melted down, illustrates the effectiveness of the improved air distribution throughout the grates, and also the fact that a somewhat higher rate of combustion may be normally maintained with the same efficiency. In other words, a higher output per boiler unit.

APPLICATION.

The Westinghouse New Model Roney stoker has been adopted in about fifty plants for lighting, railway, railroad and industrial service, with such good results that many equipped with the older type are voluntarily changing over to the new. The extent of application of this new type requires but brief reference. Suffice it to say that its labor-saving ability has been appreciated to such an extent that in New York, for example, some of the large power stations are now being equipped with them.

A Novel and Improved Indicator Reducing Motion.

A new and novel improved indicator reducing motion, on which patent has been lately applied for by F. H. and F. O. Ball, of the American Engine Company, Bound Brook, N. J., is seen for the first time as one of many novel details of the new American-Ball "Angle Compound" engine. It may be stated in the beginning,

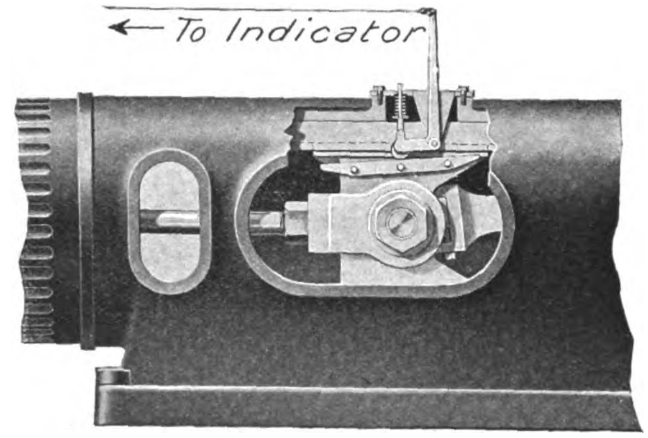


FIG. 1.—INDICATOR ATTACHED TO ENGINE.

however, that there exists no physical reason why this indicator rig should not be applied to other engines, inasmuch as its design and construction involve no features which should forbid its use on Corliss type engines, or any other type of reciprocating engine.

The illustration, Fig. 1, A and B, shows the elevation and end view of the complete rig in connection with the cross-

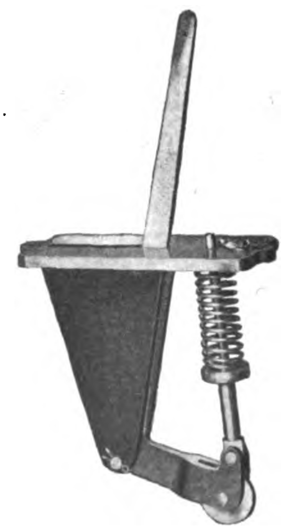

FIG. 2.—TRANSLATING LEVER.

head. It will be seen that the device consists essentially in a slotted plate through which moves an L-shaped lever. At the elbow this lever is pivoted through a bolt, at the apex of a triangular slotted plate cast as one with the outer plate of the device, and at right angles to it. The short arm of the L-shaped lever is forked. In the fork is set, by means of a pin, a small wheel or roller. Also connected with this arm is a pin which works through and at right angles to the outer plate. A helical spring, pressing against the outer plate and a disc resting on the shoulder of the pin, constantly tends to maintain the L arm at the extreme end of the slot. The device is fastened by bolts to the frame of the engine.

On the cross-head is secured, by means of bolts, a cast-iron cam plate or slide set at an angle in the vertical plane with the lower end directed away from the cylinder and at such an angle that the lower or front end is in the neighborhood of two inches below the rear end. The angle of this cam plate is determined by the length of the stroke of the engine, so that the same difference in height between the front and rear ends of the plate will be preserved in all cases. It will be seen that when the cross-head is in position nearest the cylinder the lower end of the cam plate or slide attached to the cross-head is in contact with the wheel or roller at the lower end of the L arm, and as the cross-head travels forward this wheel or roller with its arm is raised in exact proportion to the piston travel against the pressure of the spring; the reverse taking place as the cross-head returns. The strength of the coiled spring is sufficient to prevent any lost motion with this device, even in a high-speed engine. It will furthermore appear that the adjustment of the cam plate can always be so arranged that the travel of the upper end of the L arm is exactly that desired to turn the indicator cylinder the required distance without further reduction.

Referring to Fig. 2, it will be seen that on top of the exterior plate is a small flat trigger or lock which engages with a slot milled into the spindle or pin working in and out through the plate. Thus when the pin is pushed to its extreme top position, the trigger can be slipped into the slot and the rig instantly thrown out of engagement. It is but the work of an instant to release the trigger and to throw the indicator rig into service.

As far as the exterior appearance of this rig is concerned, the only visible portion is a highly polished oblong metal plate on the engine frame with a slot through which projects a six or seven-inch lever with a hole in the top. The indicator cord may be kept constantly attached to the lever and cards taken continually, if so desired, on the rig thrown in and out of service as many times as desired by the simple turn of a wrist.

A New Ward Leonard Battery-Charging Rheostat.

Based upon a clear understanding of the work of a battery-charging rheostat and the requirements of an apparatus for this service, the Ward Leonard Electric Company, Bronxville, N. Y., has made a new departure in storage-battery rheostat design. A given minimum number of cells has a fixed minimum voltage, which in charging are opposed to the line-charging

FIG. 1.—TYPE MC BATTERY-CHARGING RHEOSTAT.

volts; the difference between the battery volts and the line-charging volts is the maximum volts applied to the rheostat. In the Ward Leonard MC type rheostat, illustrated herewith, there are several switches in parallel, each switch controlling its respective resistance. Each resistance is designed to carry the maximum amperes that can be made to pass by the maximum volts that can be applied as stated above. To secure any charging amperes within the rating of the rheostat it is merely necessary to close the proper switches. There are five switches giving thirty-one steps of control. Each switch is marked with the approximate amperes that will pass when it is closed

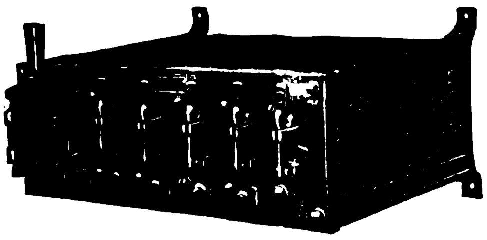

FIG. 2.—TYPE MC RHEOSTAT WITH LINE SWITCH AND FUSES.

and all the other switches are open. By reading the switch markings the approximate charging amperes are gotten at a glance. It is impossible to cause an overload through the circuit, the cells being thoroughly protected from abuse.

The resistance elements are the standard Ward Leonard enameled resistance units. They are fireproof, strong and light, and are protected against chemical, electrical and mechanical depreciation. Any rheostat of the MC type, designed for a minimum number of cells, can be used to charge a greater number of cells but at a slightly decreased charging rate.

Twelve is the minimum number of cells used in electric carriages. Therefore the minimum battery volts are approximately twenty-four. Twenty-four volts opposed to a 120-volt line circuit leaves ninety-six volts to be used up in the rheostat. For pleasure carriages forty amperes are the maximum charging amperes. An MC rheostat as described, for twelve cells and forty amperes charging rate, has each switch and its resistance designed to be connected across ninety-six volts, and when all the switches are closed forty amperes will pass through

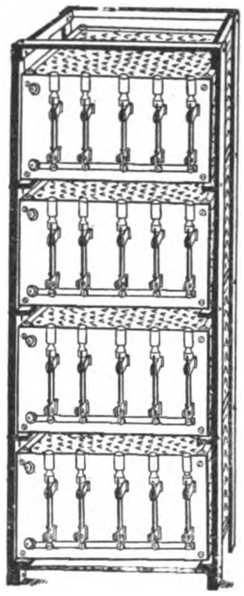

FIG. 3.—BANK OF TYPE MC SWITCHES FOR GARAGE SERVICE.

the circuit. Such a rheostat can be used to charge the following number of cells at the following charging rates:

With 12 cells in circuit a maximum charging rate of 40 amperes is obtained.
With 24 cells in circuit a maximum charging rate of 38 amperes is obtained.
With 30 cells in circuit a maximum charging rate of 28 amperes is obtained.
With 36 cells in circuit a maximum charging rate of 22 amperes is obtained.
With 40 cells in circuit a maximum charging rate of 18 amperes is obtained.
With 44 cells in circuit a maximum charging rate of 15 amperes is obtained.

Such a rheostat designed for any fixed number of cells is stated to be absolutely "fool-proof." The greater the number of cells the smaller the rheostat and the less the cost.

Fig. 1 shows the MC type rheostat as described; Fig. 2 shows this rheostat with a line switch and fuses added, making a complete installation, and Fig. 3 shows a bank of these rheostats for garage service.

Educational Plans of Boston Edison Company.

The Edison Illuminating Company of Boston have completed arrangements with Professor Sydney Whitmore Ashe to carry on next winter a comprehensive scheme of educational work for its employés. The course which will be given beginning January 1 will be along lines somewhat similar to the educational courses carried on in the past two years by the New York Edison Company and the Brooklyn Edison Company. The number of lectures to be given will be limited to twenty, sessions being held both afternoon and evening, thus affording all employés an equal opportunity to attend. The course will be given directly under the supervision of the Edison Club, a special lecture committee being appointed for the purpose. Herbert W. Moses, president of the club, will be chairman of the committee. The lectures will be one and one-half hours in length, and will be both theoretical and practical, everything being demonstrated in an experimental manner.

Changes in Electrical Engineering Course at Cornell.

At the fortieth commencement of Cornell University, occurring on Thursday, June 18, ninety-nine students completed the course in electrical engineering, a number somewhat smaller than that of last year, when 107 completed the course.

The curriculum in electrical engineering for next year has been modified somewhat. In accordance with the plan which has been followed for several years, more time and attention will be devoted to the theory of the characteristic performance of electrical circuits and machines. To provide this time in part the mechanical laboratory practice will cease at the middle of the senior year. The complete electrical course will then consist as follows:

(1) Two recitations per week and one laboratory period per week throughout the junior year.

(2) Two lectures, two recitations, two three-hour computing periods, and two laboratory periods with one recitation per week throughout the senior year.

The instruction in electrical engineering in the junior year is intended to acquaint the students with engineering practice, and to indicate the main divisions of the field. The theoretical elements are reviewed to prepare the way for more thorough work in the senior year. During the senior year the purpose is to lay a theoretical foundation for future practice, by studying the performance of circuits and machines experimentally, and by predicting their performance from their dimensions and physical constants. During the second half of the senior year the students are provided with optional courses of a more practical nature, with a view to showing them how the theory is applied in particular lines of work, such as electric railways, transmission of intelligence, design of electrical machines, and power generation and transmission.

A Fine Edison Tungsten Exhibit.

The New York Edison Company has established, at one of its branch offices in West Forty-second street, New York city, a very effective display of tungsten lamps. Across the front of the store are two windows about sixteen feet high by ten feet wide and about six feet deep. A reflector, made up of small squares of prism glass, extends for a distance of about five and one-half feet down from the top of the window. The ceiling of each window is studded with twenty-eight 100-watt tungsten lamps, each lamp being equipped with a Holophane concentrating reflector. The sides and floor of the window are painted a dead white, and the angle at which the light strikes the window glass also increases the reflected light. Luminometer measurements in these windows gave readings ranging from ninety-three to 100 foot-candles. This, of course, is an extreme in window lighting to which few merchants would care to go. As a demonstration which attracts the attention of the passersby, however, it has been a complete success. Forty-second street, around this point, is very well illuminated, and the storekeepers are disposed to keep their windows well lighted. In spite of this generally good illumination, however, the windows of the Edison company form a remarkable contrast to the illumination all about them.

The Edison Display Window on West Forty-second Street, New York City.

President Whiteside Notes Marked Improvement in Business.

While in New York city last week, Walter H. Whiteside, president of the Allis-Chalmers Company, made the following statement to a correspondent of the *Wall Street Journal:*

"There is a marked improvement in general business. Within the last ninety days the bookings of machinery orders have increased from thirty per cent to fifty per cent of normal. The business for June to date indicates that at least sixty-five per cent of normal will be reached. New inquiries received are constantly increasing in number and volume. They are of a much more substantial character than at any time since the depression began. Their general tone denoted extensive plans in contemplation and for early development; the question of prompt shipment being already regarded an important consideration.

"The immediate requirements for a larger volume of new machinery for necessary extensions and improvements to existing plants are greater than for four years. This for the reason that with many operating companies purchases which under ordinary circumstances would have been made a year or eighteen months ago were put off, due to the monetary and other conditions, until to-day the factor of safety in these plants is becoming a serious matter and new equipment must be added.

"Unlike previous depressions, following which collections for comparatively long periods continued very unsatisfactory, there was a substantial improvement within a short time after the recent flurry, and at the present time collections are exceptionally good.

"While some difficulty may still be experienced in the way of financing entirely new undertakings, yet the financial condition of the relatively small buyer is on a sound basis and credits are about normal. In fact, the improvement in new orders placed is from the smaller class of purchasers, who are, commercially, an important factor. Of course, this class of business is widely diffused, but in the aggregate it is greatly stimulating improved trade conditions.

"The business outlook is distinctly encouraging."

Current Electrical News

DOMESTIC AND EXPORT.

NEW YORK APPELLATE DIVISION DECIDES THAT TELEPHONE SHARES ARE TAXABLE—The Appellate Division at Albany, N. Y., decided on June 19, in the case of Martin H. Glynn, comptroller, against Henry W. Conklin, as referee, and the Security Trust Company, of Rochester, that shares of stock sold on a public judicial sale by a referee who appeared by the court in an action to foreclose a mortgage are taxable under the stock transfer act of 1905. Conklin, as referee, sold at auction in Rochester 322,726 shares of Rochester Telephone Company for $250,000. The court orders judgment for the comptroller for $8,454.

HUDSON RIVER ELECTRIC POWER COMPANY'S PLANS RESTRICTED—The Public Service Commission of the Second (upstate) District of New York has abrogated the order of the commission of last December giving authority to the Hudson River Electric Power Company to issue $3,232,000 bonds under a consolidated and refunding mortgage for $30,000,000 executed by the company. This closes, for the present at least, the efforts of that company to develop on its own behalf the water power of the Sacandaga River. The State Water Supply Commission is now developing plans which will be submitted to the next legislature as to the water power of the Sacandaga River.

UNFAVORABLE REPORT ON LOUISIANA TELEPHONE BILL—The senate corporations committee, by a vote of five to four, on June 16 decided to report unfavorably on Senator Stafford's bill authorizing the people of all cities over 10,000 inhabitants to nullify the action of the city councils rejecting applications for telephone franchises, by a referendum election ordered for that purpose. The bill was opposed by Mayor Behrman, Senator Voegtle, C. H. Ellis and S. Locke Breaux, who reviewed the history of telephone agitation for the past year, and explained the present *modus vivendi* under which Cumberland Telephone Company is given a year's time to improve its service and lower rates, if it be found by the board of trade committee that such reduction be justified by its revenues.

NEW ORLEANS RAILWAY AND LIGHT COMPANY'S PLANS TO RETIRE FLOATING DEBT—The New Orleans Railway and Light Company has sold to George H. Burr & Company, $1,300,000 one-year six per cent collateral notes, the proceeds of which will be used to retire the floating debt of the company. The notes are secured by the deposit of $2,400,000 of the company's general mortgage thirty-year, four and one-half per cent bonds, which have been held in the treasury. The July, 1908, and January, 1909, coupons are to remain attached to these bonds, giving them an actual face value of $2,500,000. The bonds are now selling at between seventy-two and seventy-three. The company reserves the right to retire the notes at 101 on any interest date by giving fifteen days' notice. The Whitney Central National Bank, the Hibernia Bank and Trust Company, the Canal Louisiana Bank and Trust Company and the Interstate Trust and Bank Company, all of New Orleans, have agreed to loan the company an additional $700,000 to be secured by certain real estate which the company owns not covered by the general mortgage, of a value of about $300,000, and the equity in the bonds deposited to secure the $1,300,000 loan made by Burr & Company. It is understood that about $1,000,000 of the six per cent notes have already been sold. The balance is being offered at par and interest.

THIRD RECEIVER FOR NEW YORK CITY RAILWAYS—If plans now proposed are perfected, application for a third receiver will soon be made on behalf of the protective committee of the $12,500,000 collateral trust five per cent bonds of the Metropolitan Street Railway and the $16,604,000 refunding mortgage four per cent bonds. Whether or not application will be made and receiver appointed depends upon whether the two committees can come to an understanding in the matter or not. Since the receivers took charge the Third avenue has been cut out of the system and a separate receiver for it appointed. Separate receivers have also been appointed for the Union Railway Company and for its subsidiaries and for other subsidiaries of the Third avenue. The Fulton street line has been abandoned and a receiver for the company asked. The company has outstanding $500,000 of bonds. The receivers have petitioned the court for permission to default on the rental of the Central Park, North & East River Railroad Company, and the Twenty-eighth & Twenty-ninth Streets Railroad Company, and if permission is granted separate receivers for each company are likely. The abandonment of the line of the latter company, and part, or perhaps all, of that of the former company, may also follow. Up to the present time the defaults of the receivers amount to $7,751,308. This amount does not include the seven per cent dividend on Metropolitan's $52,000,000 stock or the rentals on the Central Park, North & East River Railroad and the Twenty-eighth & Twenty-ninth Streets Crosstown Railroad. In the face of these heavy defaults it has been necessary for the receivers to sell $3,500,000 receivers' certificates in order to get funds with which to put the lines in shape for operation.

FIRST DISTRICT PUBLIC SERVICE COMMISSION, NEW YORK, DENIES APPLICATION OF LONG ACRE LIGHT AND POWER COMPANY—Denying the application of the Long Acre Light and Power Company for permission to issue $10,000,000 of preferred stock and $50,000,000 of bonds, the Public Service Commission, on June 26, took the position that practically all the advantages of competition claimed by the applicant could be secured through the powers of the commission, while actual competition would cause inconvenience and expense to the public, and would ultimately be urged as a reason why rates should not be reduced to consumers. The Long Acre company was incorporated in 1903 for the purpose of manufacturing and distributing electricity for light, heat and power. The area to be supplied was at first defined as bounded by Fifty-ninth street, Fifth avenue, Thirty-third street and the Hudson River, but in 1907 it was extended to include all of the boroughs of Manhattan and The Bronx. The intent was to enter the field as a competitor of the New York Edison Company. The Long Acre company has $50,000 in capital stock and $500,000 in bonds outstanding. The proposed new issue of preferred stock was to be non-voting. Of the $50,000,000 of bonds it was proposed to issue at the present time only $12,000,000. They were to pay interest at the rate of six per cent and run for fifty years. The company also applied for permission to execute a mortgage on all its property, present and future, to secure the bonds. The company's application, when received by the commission, was referred to Commissioner Maltbie, who held numerous hearings, at which arguments for and against the application were made. Mr. Maltbie's report, which was unfavorable to the application of the company, was made on June 26 and adopted by the commission, and on his recommendation an order denying the application was issued.

OBITUARY NOTES.

MR. M. C. MILLS, assistant superintendent of the Meadville & Cambridge Springs Street Railway Company, Meadville, Pa., died on Saturday, June 20, from injuries received in a collision on the morning before.

MR. WILLIAM HAMILTON YOUNG, manager of the Washington (D. C.) office of the Western Union Telegraph Company, and familiarly known throughout the United States as Colonel "Ham" Young, died on June 19 at the home of his son, Frank M. Young, in Chicago, Ill. Mr. Young was on duty connected with the Republican national convention, and was taken ill on the Thursday before his death at the Coliseum. He was one of the first telegraph operators of the country, and was the retiring president of the Old Time Telegraphers' Association. He entered the telegraph service in 1850, and during the Civil War served in the War Department.

ELECTRIC LIGHTING.

WATERVLIET, MICH.—The electric light plant at Manton is to be operated by power from Cedar Creek.

DETROIT, MICH.—Tekonsha has voted down a proposition to bond the town for $12,000 for the purpose of installing a municipal electric light plant.

MILFORD, N. H.—Extensive improvements are being made at the electric light plant, including the addition of new machinery and a new chimney.

MARLBORO, MASS.—The Marlboro Electric Company will furnish current to the new municipal electric light plant which is to be erected at Shrewsbury at a cost of $15,000.

FALL RIVER, MASS.—The contract for installing an electric lighting plant in the Nos. 1 and 2 Granite mills has been awarded to Potter & Earle. About 3,000 lights will be required.

HAILEY, IDA.—The Idaho Consolidated Mines Company, Limited, has completed a hydroelectric plant at a cost of over $50,000. The power used is derived from Wood River, and will develop 1,200 horse-power.

ROSALIA, WASH.—Work has been begun on the lighting system here. Practically every business house in Rosalia will be supplied and numerous residences are being wired. The work will be pushed as rapidly as possible.

BINGHAMTON, N. Y.—The board of contract and supply has awarded a three-year contract to the Binghamton Light, Heat and Power Company. This will effect a saving of $13,000 as compared with the present cost of lighting.

CARROLLTON, KY.—The city council of Carrollton has let the contract for a new electric light plant. The contract includes a new 250-horse-power engine, a 250-kilowatt dynamo, and the erection of a new building, amounting to $19,200.

HARTFORD, CT.—The following directors of the Farmington River Power Company were elected at the annual meeting: E. B. Bennett, Henry Roberts, Atwood Collins, A. C. Dunham, John S. Hunter, H. C. Judd, W. W. Smith, James Terry.

BRISTOW, OKLA.—An election has been called for July 6 at which time the electors will vote on the proposition of a $35,000 bond issue for the purpose of installing a water system. It is planned to install a municipal light plant also.

TOPPENISH, WASH.—At a meeting of the city council A. H. Campbell and M. Kramer, of Seattle, were given a franchise to furnish electric lights and power for the city of Toppenish. The work is to begin on the plant within sixty days and to be completed within six months from date.

PATCHOGUE, L. I.—The village trustees have concluded a contract with the Patchogue Electric Light Company for lighting the village streets for five years. Under the contract the light company is to furnish 125 or more twenty-five-candle-power, metallized-filament lamps for $18 per year per lamp.

ATCHISON, KAN.—A contract for rebuilding the electric lighting system of the Atchison Railway, Light and Power Company has been let to the General Electric Company, of Schenectady, N. Y., at its bid of $23,640. The changes include new generators in the power-house, new arc lights in business houses and for street lighting, etc. The work will be in charge of Leonard Schaeffer.

SPEARFISH, S. D.—The success of the electric power and lighting plant, recently installed eight miles below this city by a syndicate of Spearfish men, has led the company to seek a location for another plant. One of the largest canal systems in the Black Hills will be built. The canal will furnish power to run an electric power plant at Beulah, Wyo., developing 1,800 horse-power. The power will be used in the mines of the Black Hills.

SALT LAKE CITY, UTAH—Engineers of the Utah Light and Railway Company are busily engaged preparing plans for the power plant to be built in Weber Cañon by the Harriman system. Actual construction work will begin within a few weeks, and the plant will be completed and ready for use this fall. The plant will generate 3,000 horse-power, which will be distributed in Salt Lake and Ogden. A dam for the conservation of water will be built on the Weber River, just above Devil's Gate.

DENVER, COL.—George Pullman Sanger, J. M. Blincoe and C. W. Lathrop have secured a franchise to furnish Arvada with electric light, and filed incorporation papers with the secretary of state for the Arvada Electric Company. They will spend $32,000 on a transformer plant in the town, to be furnished with power by the Denver Gas and Electric Company. The plant will provide electricity for light and fuel purposes and for commercial service. Later the company will operate in other parts of Jefferson County.

PUEBLO, COL.—The directors of the Colorado & Kansas Power and Transmission Company at a recent meeting elected the following officers: President, S. H. Atwater, of Cañon City; vice-president, Henry Warner, of Garden City, Kan.; treasurer, W. O. Bourne, of Dodge City, Kan.; secretary, E. W. Palmer, of Pueblo, and assistant secretary, L. M. Markham, of Garden City, Kan. Andrew McClelland, of Pueblo, tendered his resignation as a director. Surveyors are in the field and it is thought that work on the Cañon City-Pueblo branch of the project will be started within the next few weeks.

LANCASTER, N. H.—The electric light company formerly owned by Jones & Linscott has passed to a stock company in which the former owners are heavy stockholders. The new company will be known as the Jones & Linscott Electric Company, and is incorporated under the general laws of the state. The new company has among its stockholders a number of business men of the town. Officers have been chosen as follows: President, Harry H. Jones; treasurer, Fred S. Linscott; clerk, Merrill Shurtleff. Directors: Mr. Jones, Mr. Linscott, Mr. Shurtleff, C. W. Sleeper and W. H. McCarten.

DOVER, N. J.—The common council has entered into a ten-year contract with the Dover Electric Light Company for lighting the streets of the town at a rate slightly in excess of the rate of the old contract which expired July 1. The new contract allows $85 a year for each arc lamp, the same as heretofore, and $17 a year for each incandescent lamp, an increase of $1 per lamp. As a partial offset to the increased rate, the lighting company is required to light the police station, fire-engine house and other municipal buildings free of cost. Heretofore the company has been charging meter rates for this service.

BOULDER, COL.—The announcement is made by Curtis & Hine, of Colorado Springs, that the Eastern Colorado Power Company will at once resume work with a full force on its power project in this county. The project contemplates the expenditure of over $2,000,000 and will ultimately furnish something like 30,000 horse-power from the waters of Middle Boulder Creek, supplemented by great reservoirs for the storage of flood waters. For about a month the force has been increased gradually, and 150 to 200 men are employed. The force will be increased as fast as room can be made for the men until the full force of 600 to 700 men is at work.

DATES AHEAD.

National Electrical Contractors' Association. Next meeting, Chicago, Ill., July 15-17.

Michigan Electric Association. Annual meeting, Grand Rapids, Mich., August 18-21.

International Association of Municipal Electricians. Annual convention, Detroit, Mich., August 19-21.

American Society of Municipal Improvements. Annual meeting, Atlantic City, N. J., October.

Illuminating Engineering Society. Annual convention, Philadelphia, Pa., October 6-7.

American Street and Interurban Railway Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Accountants' Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Claim Agents' Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Engineering Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Manufacturers' Association. Annual convention, Atlantic City, N. J., October 12-16.

American Electrochemical Society. Fall meeting, New York city, October 30-31.

PERSONAL MENTION.

MR. C. E. CORRIGAN, vice-president of the National Metal Molding Company, Pittsburg, Pa., was a New York visitor last week.

MR. T. F. SALTER, well known as an engineer in the field of hoisting and conveying apparatus, has been appointed to a new position as chief engineer of the Standard Roller Bearing Company, of Philadelphia, Pa.

MR. C. C. ADAMS, vice-president of the Postal Telegraph-Cable Company, has been receiving congratulations for the masterly and able manner in which he handled the telegraph facilities at the recent Chicago Republican convention.

MR. C. J. H. WOODBURY was the recipient of the degree of Doctor of Science, conferred by Dartmouth College, at its commencement, June 24, this being the second time he has received the same degree, the first being from Union College, New York, in 1906.

MR. AND MRS. WILLIAM J. DENVER, of Roxbury, Mass., announce the engagement of their daughter, Julia, to Mr. John W. De Crow, Yale, class of 1900. Mr. Denver is well known throughout telephone circles as the assistant general manager of the New England Telephone and Telegraph Company.

MR. W. N. RYERSON, whose election to the presidency of the Canadian Electrical Association was announced last week, was born in New York city in 1874. He was educated in the public schools and graduated in 1896 from the electrical engineering course of the School of Mines, Columbia University. After graduation he served for one year with the Sprague Electric Elevator Company in the testing and drafting departments. He then worked for six months with the Western Electric Company, in the switchboard designing department. For three years he worked with the Metropolitan Street Railway Company, New York city, in the construction and operating departments, and for three and one-half years was with the Manhattan Railway Company, New York city, and later with the Interborough Rapid Transit Company, first as chief operator of the generating station, and for the last two and one-half years as superintendent of substations for the Manhattan Elevated system and the New York city subway. Since April 1, 1905, Mr. Ryerson has been superintendent of the Ontario Power Company, of Niagara Falls, Ontario, in charge of construction, operation and local business management, including supervision of the sale of power. He is an associate member of the American Institute of Electrical Engineers, a member of the American Society of Mechanical Engineers, and a member of the Canadian Society of Civil Engineers.

MR. W. N. RYERSON.

NEW INCORPORATIONS.

LANSING, MICH.—Home Telephone Company, Mulford. $15,000.

HARRISBURG, PA.—Mount Bethel & Mount Aetna Telephone and Telegraph Company, Myerstown. $10,000.

AUSTIN, TEX.—Postal Telegraph and Cable Company, of Texas. Capital decreased from $2,000.000 to $120,000.

MADISON, WIS.—Amacoy Telephone Company, Bruce. $1,000. Incorporators: E. C. Campbell, Burt Stevens and others.

COLUMBUS, OHIO—The Falls Heat, Light and Power Company, Cuyahoga Falls. $10,000. Incorporators: W. A. Scarl, S. D. Tifft, W. B. Middleton, C. A. Davis and C. K. Fowler.

LITTLE ROCK, ARK.—People's Light, Water and Power Company, of Newport. $25,000. Incorporators: F. R. Suits, president; George O. Beebe, secretary-treasurer, and Henry Baldus.

SPRINGFIELD, ILL.—McHenry Electric Service Company. To operate an electric light and power plant. $25,000. Incorporators: G. K. Paige, L. Howell, P. J. Boonstra, Chicago.

RALEIGH, N. C.—The Green River Telephone Company, of Rutherfordton. To construct and operate a telephone line from Rutherfordton to Green River, Polk County. $10,000 capital. Incorporators: John C. Mill, Poe W. Eskridge.

ELECTRICAL SECURITIES.

In many quarters there is a well-defined impression that the stock market is due some time during the summer for another advance in prices, and this of substantial proportions. The reasons for this are not just now apparent, although reports are not disquieting, so far as business in general for this time of year is concerned. In fact the electrical field is feeling the impulse of a greater confidence in the near future, and, although business has fallen off very materially, orders in hand indicate a greater activity than was expected a month or two ago.

Dividends have been declared upon the following electrical securities: New England Investment and Security Company; regular semiannual dividend of 2 per cent on the preferred stock, payable July 1 to stock of record June 20. Washington Water Power Company, of Spokane, Wash.; regular quarterly dividend of 1¾ per cent, payable July 1 to stockholders of record June 20. Manila Electric Railroad and Lighting Company; regular quarterly dividend of 1 per cent, payable July 1 to stockholders of record June 20. Rochester (N. Y.) Street Railway Company; regular quarterly dividend of 1¼ per cent on the preferred stock, payable July 1 to stock of record June 23. Radio Telephone Company; regular quarterly dividend of 1 per cent and an extra dividend of 2 per cent, payable July 15 on stock for which full cash payment has been made prior to July 1, 1908. New York & New Jersey Telephone Company; regular quarterly dividend of 1¾ per cent, payable July 15 to stock of record July 6. Electric Storage Battery Company, Philadelphia Pa.; quarterly dividends of ¾ of 1 per cent on both common and preferred stocks. This compares with 1 per cent on each stock three months ago, and six months ago 1¼ per cent on each stock. The dividends were payable July 1. Mexican Telegraph Company; regular quarterly dividend of 2½ per cent, payable July 16. Bell Telephone Company of Pennsylvania; regular quarterly dividend of 1½ per cent, payable July 15 to stock of record July 3. Massachusetts Lighting Company; regular quarterly dividend of 1½ per cent, payable July 15 to stock of record July 1. Commonwealth Edison Company; quarterly dividend of 1¼ per cent, payable August 1. Philadelphia Company; regular quarterly dividend of 1½ per cent on the common stock, payable July 1. West India Electric Company; quarterly dividend of 1 per cent, placing the stock on a 4 per cent basis.

ELECTRICAL SECURITIES FOR THE WEEK ENDED JUNE 27.

ELECTRIC RAILWAYS.

MARION, IND.—Surveys have been begun for the new Marion-Logansport traction line, under the direction of Henry F. Coleman, of Logansport.

DOVER, N. J.—Salmon Brothers, of Ledgewood, have the contract to build the trolley line from Silver Spring Park to Bertrand Island, on the east side of Lake Hopatcong.

SHERMAN, TEX.—The longest interurban electric railway in the Southwest was finished on June 16. It is sixty-seven miles long and runs between Sherman and Dallas.

PORTLAND, ORE.—The power plant of the Portland Railway, Light and Power Company at Cazadero was partially destroyed on June 21. The plant is valued at $750,000.

PHILADELPHIA, PA.—The Northern Cambria Street Railway Company, operating out of Johnstown, Pa., and connecting important towns, has decided to issue $100,000 bonds to build to the town of Hastings.

JANESVILLE, ILL.—Judge Grimm, in the Circuit Court, having decided that the franchise granted the Rockford & Interurban Railway Company was not properly granted, a new franchise will be prepared and submitted to the town council.

NEW YORK, N. Y.—At a meeting of the board of estimate and apportionment a resolution was adopted granting the petition of the New York & Queens County Railway for a franchise to extend its road to Eleventh avenue and Thirty-sixth street, in the old village of Whitestone.

LA JUNTA, COL.—The articles of incorporation of the Kansas-Colorado Electric Railway and Power Company have been forwarded to the secretary of state at Denver for filing. This is the company which proposes building an electric line from Dodge City, Kan., to Cañon City.

BALLSTON, N. Y.—Frederick H. Beach was appointed receiver, on June 23, of the Eastern New York Railroad Company, an electric line twelve miles long. The industrial depression and financial panic, together with the failure of the Philadelphia banking house which carried the railroad's bonds, caused the receivership.

DENVER, COL.—O. F. Olson, who has been completing arrangements for the construction of the new electric line from Fort Collins, Col., to Hudson, has signed a contract with the Burlington Railroad for the delivery of the rails and ties at Hudson to build the line from Hudson to Kersey. He also signed a contract with a construction party.

GREELEY, COL.—D. A. Camfield proposes to build an electric railway from Greeley to Pleasant Valley. To do this it is said he will interest the Home Electric Light Company and secure power from its plant. If the road is built, it will be completed in six months and may be the forerunner of other lines to operate with Greeley capital.

MONTREAL, CANADA—The Montreal & Southern Counties Railway Company has opened offices at 605 and 606 Canadian Express Building, McGill street, Montreal. W. B. Powell is manager, and J. A. Burnett, superintendent and electrical engineer. Work is now proceeding on the Montreal-St. Lambert section of this road, and entry into the city of Montreal has been arranged for.

TACOMA, WASH.—The construction crew on the Tacoma-Seattle short line has been increased and the building of the line will progress rapidly all summer. Grading crews have been at work south of Young's cove on the north end of the line since the middle of May. Merle J. Wightman, one of the promoters of the road, is authority for the statement that the right of way has been secured and the location between Seattle and Des Moines decided on.

BELLEFONTAINE, OHIO—Citizens of Degraff and Bellefontaine are planning to build an electric line between the two towns. The management of Silver Lake Park, which lies between the two places, is also interested in the enterprise, and the Schoepf syndicate, controlling the Ohio Electric Railway system, which has a trunk line through Bellefontaine, has agreed to sell the power to this proposed new line, believing it would prove a valuable feeder.

FLINT, MICH.—In accordance with an order by Circuit Judge Wisner, the Detroit, Flint & Saginaw Electric Railroad, which has fourteen miles of road in operation, has been sold at public auction. Isaac Applebaum, of Detroit, who holds the bonds of the road to the amount of $250,000, was awarded the property on his bid of $50,000. The Detroit Trust Company, of Detroit, has been acting as receiver for the property. It is said that Mr. Applebaum will complete the construction of the line to Flint.

PITTSBURG, PA.—After two years' labor and the expenditure of more than one million dollars, the Ardmore Street Railway Company has completed its road between Wilkinsburg and East Pittsburg. The initial trip was made on June 19. The officers of the Ardmore Street Railway Company are: William Flinn, president, and George H. Flinn, treasurer. The directors are: William and George Flinn, John S. Weller, H. P. Haas and M. K. McMullin. The cars will be run on a ten-minute schedule until midnight.

STUART, IOWA—The first annual meeting of the stockholders of the Red Oak & Northwestern Interurban Railway Company was held recently at Red Oak. Twenty directors were elected. They are: B. B. Clark, A. R. Tracy, H. E. Dermer, Thomas Griffith, Gordon Hayes, O. J. Gibson, George C. Boileau, of Red Oak; L. D. Foote, S. E. Smith, of Grant; F. D. Martin, W. L. Battin, of Greenfield; F. O. Hinkson, J. R. Smull, A. C. Curtis, of Stuart; D. A. Field, G. W. Curtis, of Redfield; George W. Clarke, J. W. Russell, of Adel; N. C. Wragg, Nathan Nish, of Waukee. An executive committee was elected consisting of F. O. Hinkson, Stuart; W. L. Battin, Greenfield; George C. Boileau, O. J. Gibson and Gordon Hayes, of Red Oak. B. B. Clark was elected president, George W. Curtis, vice-president; M. N. Spencer, secretary, and Thomas Griffith, treasurer. The company is formed for the purpose of building an interurban railway from Red Oak through Grant, Greenfield, Stuart, Redfield, Adel, Waukee and to Des Moines. Much interest is manifested along the proposed route.

NEW MANUFACTURING COMPANIES.

BROOKLYN, N. Y.—The Gore Arc Lamp Company has been incorporated with a capital of $50,000 to manufacture arc lamps. The incorporators are: G. I. Woolley, H. T. Berry and H. T. Asbury, Brooklyn.

JERSEY CITY, N. J.—The National Ignition Company has been incorporated to manufacture electrical devices and appliances, with a capital of $150,000. The incorporators are: F. C. Eberlin, A. Williams and G. W. Flaacke, of Jersey City.

INDUSTRIAL ITEMS.

THE H. KRANTZ MANUFACTURING COMPANY, 160 Seventh street, Brooklyn, N. Y., is distributing a series of advertising folders devoted to its water-tight floor boxes and switchboards.

THE CUTLER-HAMMER MANUFACTURING COMPANY, Milwaukee, Wis., is preparing to manufacture snap switches and lamp sockets in addition to the circuit-breakers and controlling devices of which it now makes a specialty.

THE F. BISSELL COMPANY, 226 Huron street, Toledo, Ohio, is celebrating the month of July with a calendar card to which is attached an imitation fire-cracker. The inference is that "it can't possibly hurt you" to give the company an order.

THE BROWN HOISTING MACHINERY COMPANY, Cleveland, Ohio, will be pleased to send to any one interested upon request its "O" catalogue, describing and illustrating "Brownhoist" machinery as adapted to the use of artificial gas, coke and electric light companies for the rapid and economical handling of coal, coke and other materials.

THE H. W. JOHNS-MANVILLE COMPANY, 100 William street, New York city, has ready for distribution a circular describing its "Ferro" compound. This compound is a chemical iron cement for smoothing over and filling up blow holes, sand holes, etc., in iron and steel castings. Literature is also ready for distribution describing the company's "Anti-Sweat" pipe covering.

THE EDISON MANUFACTURING COMPANY, Orange, N. J., announces that, in the oil fields, gas engines are running twenty-four hours a day, seven days in the week, using Edison primary batteries, which do not have to be looked after, as far as their ignition is concerned, more than once or twice a year. At such times a few minutes are required to renew the cells.

THE ACHESON OILDAG COMPANY, Niagara Falls, N. Y., manufacturer of "Oildag" and "Aquadag," has elected the following officers: President, Edward G. Acheson, Jr.; secretary, W. H. Arison; treasurer, A. M. Williamson. The president is a son of the well-known inventor and electric furnace expert, Edward Goodrich Acheson, who discovered the "Oildag" and "Aquadag" processes. The company's offices and works are at Niagara Falls.

THE TRIUMPH ELECTRIC COMPANY, Cincinnati, Ohio, has ready for distribution a new bulletin entitled "Some Illustrations of the Triumph Motor Drives." This bulletin does not go into the details of construction, but shows particularly by means of illustrations the application of motors to the various types of machines, such as lathes, planers, printing presses, boring mills, hoists, etc. Copies of this bulletin will be furnished upon request.

W. N. MATTHEWS & BROTHER, 227 North Sixth street, St. Louis, Mo., are the selling agents for the Stombaugh guy anchors, which are in very wide use throughout the country. This anchor is operated on the corkscrew principle, going into the ground without digging a hole. Enormous strains can be put upon the anchor because it is set in the solid, undisturbed earth. Full information will be sent to those interested upon request.

THE SIMPLEX ELECTRIC HEATING COMPANY, Cambridge, Mass., has published catalogue No. 15, giving a very excellent presentation of its extensive line of heating and cooking apparatus. In addition to the descriptive matter and the large number of illustrations there is some valuable information given concerning the consumption of current and the cost of use. Copies of this catalogue will be furnished to those interested upon request.

THE GENERAL FIREPROOFING COMPANY, Youngstown, Ohio, announces the erection of an additional factory building 60 by 200 feet, which will be devoted to the manufacture of steel office furniture and office devices, including steel sections or "units," desks and tables. This furniture is finished to closely resemble oak or mahogany, and the difference can not be detected by sight alone. The steel furniture possesses advantages over wood in that it is fire-resisting, space-saving, durable and not affected by moisture.

THE CENTRAL ELECTRIC COMPANY, Chicago, Ill., is distributing a circular containing some valuable engineering data on the economy of the new "silico-vanadium" steel used in Pittsburg transformers. This comprehensive article is in the form of a six-page bulletin showing the difference between "high-efficiency" and "standard-efficiency" transformers, and is reduced to a dollars-and-cents basis. In computing core-loss costs the author has adopted one cent per kilowatt-hour as a basis, and a comparison is made between the actual cost of the two types of transformers.

THE SUNBEAM INCANDESCENT LAMP COMPANY, West and Bethune streets, New York city, has been meeting with great success in its exportation of American-made tungsten lamps. One of its correspondents in South Africa has recently sent the following communication to the company: "I have just heard from one of my customers, for whom you furnished the only lot of tungsten lamps for me, that those lamps which you sent are the best lamps in the market, and that in spite of the higher price he is ordering some more. This I am extremely glad to hear, and I hope that as a result of the trial he has given them a good market for the lamps out here may result. The lot which you furnished me came out with very slight breakage; in fact, there were only six lamps out of 150 which were broken in transit or in any way defective."

Record of Electrical Patents.

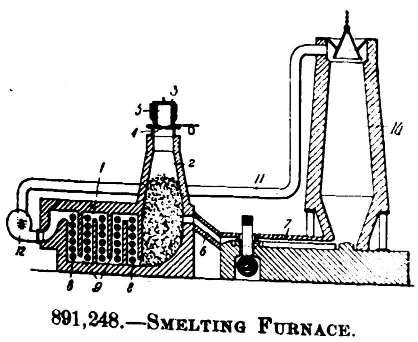
Week of June 23.

891,232. LIQUID RHEOSTAT. Herbert W. Cheney, Norwood, Ohio, assignor to Allis-Chalmers Company. The resistance is varied by raising one of the plates out of the electrolyte.

891,236. ELECTRIC-MOTOR CONTROLLER. John Dillon, Milwaukee, Wis., assignor to the Barth Elevator Company, Milwaukee, Wis. A relay switch is provided in the main circuit on each side of the motor, these being controlled by a derived circuit which includes the switches cutting out the starting resistance.

891,241. METHOD OF AND MEANS FOR STARTING DYNAMO-ELECTRIC MACHINES. Budd Frankenfield, Norwood, Ohio, assignor to Allis-Chalmers Company. The motor being driven above synchronism by an auxiliary motor.

891,248. SMELTING FURNACE. Eugen A. A. Grönwall, Ludvika, Sweden. The combination of a smelting furnace and an electrically heated refining furnace.



891,248.—Smelting Furnace.

891,254. ELECTRICAL WATER HEATER. Harry M. Hill, St. Louis, Mo., assignor to Hill Electrical Manufacturing Company, St. Louis, Mo. The water is passed between two conical electrodes.

891,263. ELECTRICAL APPARATUS. Charles J. Klein, New York, N. Y., assignor to Ralph A. Schoenberg, New York, N. Y. An outwardly opening plug receptacle.

891,264. DEVICE FOR THE PURIFICATION OF METALS. Charles T. Knipp, Urbana, Ill. A device for volatilizing a metal *in vacuo*.

891,265. PROCESS FOR PURIFICATION OF METALS. Charles T. Knipp, Urbana, Ill. The metal is volatilized in a vacuum by an electric arc and then condensed.

891,273. CLAMPING MEANS FOR CORE-PLATES OF DYNAMO-ELECTRIC MACHINES. Charles E. Lord and William H. Powell, Norwood, Ohio, assignors to the Bullock Electric Manufacturing Company. The core support is provided with an abutment and a circumferential groove in which a locking ring is seated.

891,303. SIGNALING SYSTEM FOR RAILWAYS. Louis H. Thullen, Edgewood Park, Pa., assignor to the Union Switch and Signal Company, Swissvale, Pa. A block-signaling system for alternating-current railways, one rail of which serves as the return for the power current.

891,306. ROTARY OIL-SWITCH. Hermon L. Van Valkenburg, Norwood, Ohio, assignor to the Bullock Electric Manufacturing Company. The contact fingers and drum are placed within a tank of oil.

891,316. DYNAMOELECTRIC MACHINE. Robert B. Williamson, Norwood, Ohio, assignor to Allis-Chalmers Company. The commutator segments are supported throughout almost their entire length and held in position by four locking rings.

891,320. INDUCTION COIL. Donald H. Yost, York, Pa., assignor of one-half to Frederick R. Yost, York, Pa. An electromagnet for bridging openings in an electric circuit.

891,323. FUSE. Bert A. Brown, Churchville, N. Y. A signal is set by the burning of the fuse.

891,339. RAILWAY SIGNAL. Franz Hirt, Berlin, Germany, assignor to General Electric Company. A railway signal responsive to polarized light only.

891,343. FLEXIBLE ELECTRICAL CONNECTION DEVICE AND THE LIKE. Charles A. Keller, Paris, France. A connection comprising a pair of laminated strips.

891,350. GENERATION AND TRANSMISSION OF MOTIVE POWER. George W. Mascord, London, England. A supplementary engine is automatically thrown in service when the load on the main engine exceeds a predetermined value.

891,352. TOWING SYSTEM. Wilbur L. Merrill, Schenectady, N. Y., assignor to General Electric Company. The barges are towed by a cable wound on a drum, the unwinding of which, due to increased pull on the cable increases the torque of the winding motor attached to the drum.

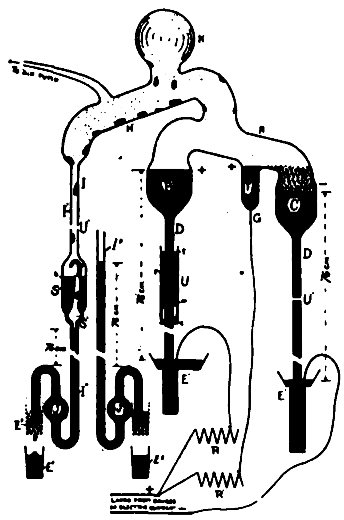
891,361. MEANS FOR ELECTROPLATING RODS, PIPES, ETC. Daniel H. Murphy, New Castle, Pa. Means are provided for rotating the pipe while plating.

891,395. TREATING SLIMES FROM ELECTROLYTIC REFINING OF LEAD. Anson G. Betts, Troy, N. Y. The slime is oxidized and then melted with a reducing agent to remove antimony.

891,400. ELECTRIC HEATER AND MEANS FOR CONTROLLING THE SAME. Peabody A. Brown, Denver, Col. The resistance elements are wound on a series of cores.

891,410. TROLLEY FOR ELECTRIC CARS AND THE LIKE. Edward J. Dacey, Prescottville, Pa. The wheel is mounted on a spring-supported swiveling cylinder.

891,414. THERMAL CUTOUT. Charles A. Ernst, Schenectady, N. Y., assignor to General Electric Company. An indicating fuse is carried on the outside of the case enclosing the main fuse.

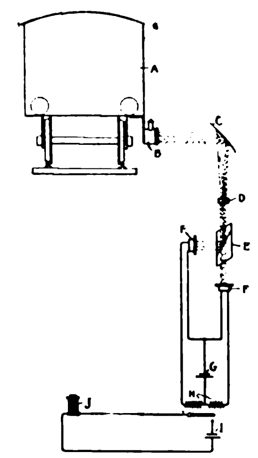


891,264.—Device for the Purification of Metals.

891,425. LIMIT-SWITCH DEVICE. Sam H. Kanmacher, Schenectady, N. Y., assignor to General Electric Company. A reversing controller with overload relays.

891,455. HOT-WATER HEATER. George L. Bennett, Trenton, N. J. A combined water heater, faucet and valve.

891,463. ELECTROTHERMAL PROTECTOR. Frank B. Cook, Chicago, Ill. A combined thermostat and lightning arrester.



891,339.—Railway Signal.

891,496. ELECTRICAL TRANSFORMER. August R. Luschka, River Forest, Ill., assignor to Western Electric Company, Chicago, Ill. An induction coil with the primary and secondary windings arranged in the form of two hollow truncated cones.

891,556. AUTOMATIC TRAIN-STOP. Joseph H. Lynch, Red Bank, N. J. A magnetically controlled pneumatically operated device for cutting off power and applying the brakes.

891,561. COMBINED ELECTRIC SERVICE CUTOUT AND METER BOARD. Henry E. McGowan and Edwin R. Ellsworth, New York, N. Y. Space is provided on the service board for the meter.

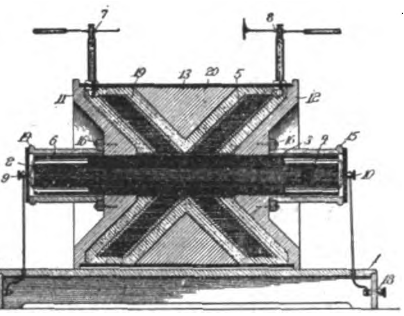
891,589. AUTOMATIC ELECTRIC REGULATOR. William L. Bliss, New York, N. Y. A regulator for controlling the voltage of a distributing system utilizing a storage battery.

891,617. ELECTRIC SWITCH-OPERATING MACHINE. Leslie A. Hedger, Mill Valley, Cal. The switch is operated by a coil and plunger magnet.

891,632. ELECTRIC BRAKE MECHANISM FOR CARS, ELEVATORS, CRANES AND OTHER PURPOSES. Michael E. Neenan, New York, N. Y., assignor to Otis Elevator Company, Jersey City, N. J. The spring-applied brake is retracted by an electromagnet, a supplemental magnet applying additional pressure on the brake-shoes when seated.

891,657. APPARATUS FOR THE ELECTRICAL PRODUCTION OF HEAT FOR COOKING AND OTHER PURPOSES. Arthur F. Berry, Ealing, England. The heating currents are induced in the heating element.

891,712. TROLLEY. Abel Molinar, Pittsburg, Pa. Spring-controlled wire guards are attached to the wheel.



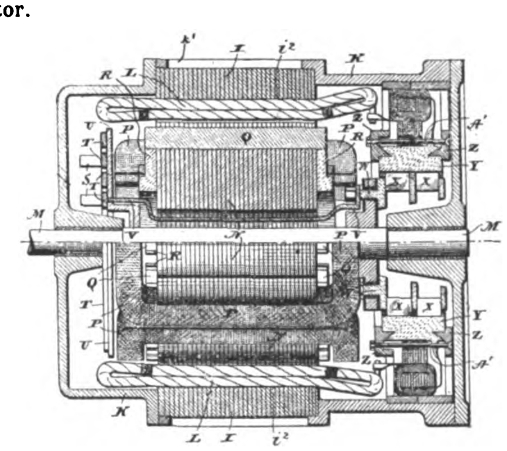
891,496.—Electrical Transformer.

891,720. MOTOR-CONTROLLING DEVICE. William C. O'Brien, Baltimore, Md., assignor to Monitor Manufacturing Company of Baltimore City, Baltimore, Md. A switch shunting the starting resistance is controlled by two solenoids, so that the resistance is cut out when the armature current has fallen to a certain value.

891,721. STARTER FOR ELECTRIC MOTORS. William C. O'Brien, Baltimore, Md., assignor to Monitor Manufacturing Company of Baltimore City, Baltimore, Md. A rocking switch controlled by two solenoids in the motor circuit which cuts out the starting resistance.

891,722. STARTER FOR ELECTRIC MOTORS. William C. O'Brien, Baltimore, Md., assignor to Monitor Manufacturing Company of Baltimore City, Baltimore, Md. A series of switches for cutting the starting resistance out of the motor circuit in steps, the action being controlled by two solenoids.

891,779. ELECTRICALLY GOVERNED AUTOMATICALLY OPERABLE TRAIN CONTROLLING SYSTEM. Harvey B. Miller, Staunton, Va., assignor of one-half to James A. Bell, Staunton, Va. An electromagnetic means for disconnecting the current collector.



891,784.—Single-Phase Commutator Motor.

891,780. AIR-BRAKE APPARATUS. Harvey B. Miller, Staunton, Va., assignor of one-half to James A. Bell, Staunton, Va. An electromagnetically controlled air-brake valve.

891,784. SINGLE-PHASE COMMUTATOR MOTOR. Stanley S. Seyfert, South Bethlehem, Pa., assignor of one-half to William S. Franklin, South Bethlehem, Pa. The commutator is attached to the outer stationary element of the motor.

891,786. TELEPHONE SYSTEM. Nathan H. Suren, Highlandville, Mass., assignor to the Gamewell Fire Alarm Telegraph Company, New York, N. Y. A combined signaling system and telephone.

891,797. METHOD OF AUTOMATIC REGULATION OF RECTIFIERS AND ROTARY CONVERTERS. Francis B. Crocker, New York, N. Y. The rectifier is regulated by introducing in the circuit inductance due to the combined effect of the alternating and direct currents.

CONTENTS

IMPROVED CONDITIONS IN THE ELECTRICAL INDUSTRY.

Careful inquiry among the leading manufacturers of electrical apparatus indicates that there is an increasing feeling of confidence due to the encouraging prospect of a revival in the demand for this material. The leading houses are receiving a number of inquiries through their branch offices in all sections of the country, and the business thus indicated should aggregate a considerable volume, the stimulus thus effected having a very beneficial influence upon the trade in general. Manufacturers at the present time are keenly alive to every possibility of new business, and we find in every direction a disposition to develop new lines and to meet the demands of the user of electrical apparatus more than half way in the extension of credit and in co-operation with him in the handling of orders of every magnitude.

Just as soon as the danger signals were hoisted last October retrenchment set in. To-day it is a matter of fact that there are not in hand any large accumulations of retail supplies. During the spring there has been very little stocking-up. The disciplinary regulations which have been put in force have improved labor conditions, and in its eagerness to be kept on the pay-rolls labor has become more efficient than for many a day.

Central stations, street railways, telephone and telegraph companies have cut down their operating expenses, but have continued to take on new business. In these fields there has not been the decrease in revenue which has been experienced in other phases of industry. While there may be some complaints that these utilities are not operating up to their capacities, it must be remembered that within the last two years their capacities have been very greatly increased, so that if at the present time a company is operating at only fifty per cent of its capacity, it may be operating at more than double its capacity of a few years ago.

Owing to the fact that, notwithstanding the depression, earnings have held fairly well, with the indication that if the present rate of gain is maintained, the year will close with earnings at least comparable with those of 1907—and that was a record year—there is less timidity on the part of the managements of street railway, central station and telephone and telegraph corporations to place orders for new apparatus and to undertake still greater developments. Within the last few weeks this feeling of confidence has been placed upon a dollars-and-cents basis, the reports from the leading manufacturers of the articles entering into the conduct of this industry showing that the business has been imbued with new life.

AN EXAMPLE OF UNECONOMICAL POWER-PLANT CONSTRUCTION.

Some engineers believe that power-plant design is a matter of opinion. It is, in fact, a matter of experience. Owing to a lack of experience in this particular line such engineers adhere to the unproved opinions of themselves and others, particularly those of the engineer-salesman. To what such "opinions" may lead may be seen from the following:

The design and construction of a somewhat prominent central plant for supplying heat, light and power for manufacturing purposes has recently been closely followed. Before the plans of the substructure and superstructure were completed two tall chimneys had been erected resembling obelisks in a desert. As the buildings were of later design much of the arrangement had to be accommodated to the chimneys already in place. It was the opinion of the engineers in charge that the chimneys rested on hard-pan. However, in this case the settlement of the chimneys was enough to crack the basement walls (one crack being seventeen feet long) and it was later discovered that one of the chimneys was fully a foot out of plumb.

The whole layout of the plant was practically made without any consideration of the scheme of piping. The location of the foundations, one of the most important features in the layout of power plants, was determined from unchecked pencil drawings on cheap sketch paper. The floors were made of concrete, reinforced by rods, which in itself is not good design for power-plant work, and especially as the location of the auxiliary machinery to be carried on the engine-room floor was not determined at this time. Much of the machinery, particularly that for manufacturing purposes, is located on this floor and consequently many holes had to be cut for the necessary pipes. In fact there were so many of these holes, several of which were eighteen inches in diameter, that a pneumatic drill was brought into service to cut them. A seven-and-one-half-foot octagon hole had been provided. However, when the size of the accumulator was later determined this hole had to be enlarged to nine and one-half feet square. Cutting such holes, it will be readily understood, necessitated the cutting of the reinforcement rods.

Probably one of the worst blunders made was in the erecting of the concrete basement walls. Openings were left in the concrete division wall for the piping leading from the boiler room into the generating room before the piping layout was made. Bolts were fixed in the concrete floors for pipe-hangers, and consequently when the piping layout was made the main steam pipe, which is fifteen inches in outside diameter, and the exhaust pipe had to be arranged to suit these hangers.

The boiler units installed, which are of 500 horse-power, are provided with eight-inch steam connections giving a velocity of steam of about 1,800 feet per minute, while the common practice calls for 6,000 feet, so that six-inch pipes would have been ample. The ring system is employed, the pipe being fifteen inches outside diameter, although a twelve-inch pipe, according to common practice, would serve the purpose with much better results, reducing the amount of condensation, occupying less space and being more flexible. Furthermore, the first cost would have been reduced, and at least $2,000 could have been saved on the main steam piping alone if experience had prevailed in the matter of determining the sizes instead of "opinion." The same is true as to all the other piping in the system. The engineers in charge, probably not feeling sufficiently competent, gave out to a contractor the work of designing the layout of the piping with the above result. And there is no uniformity of design in the laying out of the piping system, as there are fourteen-inch high-pressure valves provided with by-passes which in other cases are omitted, whereas the six-inch valves are all so provided. It is common practice to provide all high-pressure valves above ten-inch with by-passes.

While an unusually large amount of time was spent on drawings and specifications for the piping system, many important features were lost sight of and much time was wasted on small details. It is safe to say that there could have been saved in first cost of the complete piping system between three and four thousand dollars out of a total cost of the piping of almost $20,000, and at the same time a better and more economical system would have been secured.

The boiler room is provided with plenty of louvres which, however, are not properly placed. The ventilation in the firing aisle is poor, as the coal bunkers, designed for eighteen-ton capacity per running foot, are carried on girders seven feet nine inches deep. These girders have a span of thirty-two feet and extend down a little below the top of the boilers, cutting off the passage for light and ventilation which is considered so necessary in power-plant practice.

The engine room has two large monitors situated directly above the turbo-generators; in case of sudden rain this might readily be the cause of short-circuits. Since in this case plenty of light is secured from the windows in three sides of the engine room, these monitor windows could have been dispensed with and less expensive and more efficient means for ventilation been provided.

By adopting practically the same type of cooling tower, but set several feet lower, the water of condensation from the condensers could have circulated by gravity and the expensive hot-well tank and additional centrifugal pump for lifting the water to the cooling tower could have been dispensed with.

A very expensive reinforced concrete track scale pit, for weighing and receiving the coal, was built, the design having been complicated to an extreme in order to save a few yards of concrete. If calculation had been made it would have been found that by the use of a few yards more of concrete the design might have been simplified and seven to eight hundred dollars easily saved.

The above are a few of the gross errors made by opinionated designers who, in this case, consumed more than a whole year's time, with a staff of draftsmen, to accomplish what expert power-plant designers would have done more effectually in three to four months, and who would have saved the company some twenty-five to thirty thousand dollars in first cost as well as a very respectable sum in the annual operating expense.

THE INSTITUTE CONVENTION.

The annual convention of the American Institute of Electrical Engineers, which was held at Atlantic City, N. J., last week, was fully as enjoyable and profitable to those attending as had been expected. The weather conditions could hardly have been improved upon, as the sun shone brightly during the entire four days of the convention, yet the temperature was not uncomfortably high. In many ways Atlantic City is an ideal place for such conventions, as the accommodations for visitors are unsurpassed and there are innumerable opportunities for enjoyment besides the main attraction—sea bathing. Under these conditions it was only natural that those who were fortunate enough to be able to go to Atlantic City should have thoroughly enjoyed the four days spent there.

The only criticism which can be made of the convention, and it can hardly be called a criticism, is the amount of work expected of the attending members. It seems to be forgotten that the main object of the convention is the discussion of papers rather than their mere presentation, but this end is always defeated when the programme is crowded; and the better and more interesting the papers, the more disappointing is the result. Another unfortunate result of the plan which crowds the convention days with business sessions is the little time left to the members to become personally acquainted. To many Institute members the annual convention is the only time during the year when they can mingle with many old friends and make more new ones, but when the mornings and afternoons are both taken up with long sessions, leaving hardly time enough in between for lunch, one is more inclined in the evening to drift off into some simple amusement rather than talk shop with his brother engineers.

Various remedies can be suggested for this evil, though not any one of them is itself free from objections. The simplest plan would be to cut down the number of papers, but when there is such a large number of good papers sent in, the selection becomes a difficult and delicate task. No one side must be given preference over any other, and all the different branches of the profession expect recognition. Naturally, with these requirements before it, the Papers Committee is only too likely to err in preparing too full a programme, and the result is the worse, the better the papers. One good paper at the beginning of a three hours' session can easily provoke discussion enough to fill profitably the entire time; consequently the following papers provoke little or no discussion, as those to whom the topic is interesting are either tired and indifferent or hesitate to prolong the session, not only by the time which they themselves would use, but frequently because the man who has something worth saying hesitates to say it lest he start the discussion in a new direction. It is true the time allowed for discussion is largely in the hands of the presiding officer, but when the latter asserts his authority in order to give each of the papers, or topics, its proper portion of the time, the discussions naturally become perfunctory and lacking in value and interest.

Another plan would be to hold parallel sessions which would be devoted to subjects but little related. To those who are specialists or who are interested in but one or two branches of the electrical industry this scheme would be quite satisfactory. On the other hand, there are a great many members, besides those who are teaching, who are interested in various and unrelated topics and who would necessarily feel that they had lost something if two important papers should be taken up by two sessions at the same time.

Still a third plan would be to hold at least two general meetings of the Institute during the year. Each of these might be limited to the consideration of certain topics, so that the member who could attend but one meeting during the year would be able to select that most profitable to him. This plan also has its objections, as it is probable that there would be fewer attending each meeting than now attend the annual convention, although one of the main objects of a convention is to bring all the members of the Institute together irrespective of their special lines of work, and any plan that would interfere with this object should have very marked advantages in other ways to lead to its consideration.

The sessions of the second day of the convention, which are reported in this issue, illustrated very well the objections to the present system. The morning session had three papers dealing with transmission line troubles, while it is well known that a single paper touching upon the topic generally classified as "lightning" in Doctor Steinmetz's use of the term, is sufficient to provoke three or four hours of discussion. There was in addition a most interesting engineering paper dealing with an important transmission system which would have called for a much more general expression of views had there been sufficient time; and there was still a fifth paper which, for the same reason, received but slight attention. Naturally, with this programme before it, the morning session considerably overran the allotted time. The programme for the evening session contained but three papers, all of them, however, of unusual interest and importance. The first to be presented dealt with some interesting high-voltage experiments and would alone have proved sufficient for the session, since its discussion took up the greater part of the evening, but the other two papers were not less important, as one dealt with the design of transmission lines and the other was a tentative specification for testing high-voltage line insulators. Under the conditions, however, they could not be given the time which they deserved. It is greatly to be hoped that some plan for alleviating the conditions will be arranged. Matters were much improved at the present convention by having all of the papers printed and distributed in advance, and in many cases the author had carefully prepared abstracts, thus insuring a brief but satisfactory presentation of his paper in the time allotted to him. It would be well for those who intend to take part in the discussions to prepare their remarks in the same way. They would then be sure of saying what they intend to say, which is not always the case when they speak without notes; and much time would be saved.

Annual Convention of the American Institute of Electrical Engineers.

Report of the Discussion on Papers Dealing with Transmission Problems.

THE twenty-fifth annual convention of the American Institute of Electrical Engineers was opened at Atlantic City, N. J., on Monday morning, June 29, at 9.30 o'clock by President H. G. Stott. The report of the first day's sessions was given in the issue of the ELECTRICAL REVIEW for July 4.

The third session was opened at 9.30 A. M., Tuesday, June 30, at the Hotel Traymore, by President Stott, and three papers dealing with transmission line troubles were taken up.

E. E. F. Creighton, in a paper on "Measurements of Lightning, Aluminum Lightning Arresters, Earth Resistances, Cement Resistances and Kindred Tests," gives the results of the past year's investigations of lightning and the operation of lightning arresters. For this purpose two lines were chosen, well up in the Rocky Mountains of Colorado, and new types of apparatus for measuring the various quantities involved in lightning discharge were developed and installed. These are described in the paper, and the methods in which they were used are discussed and a good deal of data collected during the two years of study given. The paper is divided into six parts. The first discusses the duration of lightning and describes the apparatus devised for measuring this. The records were made on a rotating sensitive film. In this section, also, the methods employed for determining the flow of current are described. By placing a group of graded fuses in the discharging circuit limiting values may be determined, and when the frequency and duration and other constants of the circuit are known the quantity of discharge may be estimated. The second division of the paper discusses the frequency of the discharge. For measuring this resonators were employed consisting of coils of German silver wire such as are used for the same purpose in wireless telegraphy. The third section of the paper discusses the experience on the two transmission lines under observation. Records were kept by means of a moving tape placed in the discharge gaps. It is suggested that since the aluminum arrester is designed to operate continuously for half an hour or more, it is feasible to attach an alarm to these arresters which will signal to the operator at the station when a discharge is taking place so that he may take precautions to clear the line should the trouble continue. On two occasions it was found that choke-coils were beneficial. On several occasions one phase of a system became grounded and in each case gave rise to vicious surges on the lines. To prevent such surges from causing damage is the most difficult problem in lightning protection. The various factors influencing the general design of the aluminum-cell arrester are discussed in the next section of the paper. One feature is the disappearance of resistance in the arrester when a discharge takes place. Another is the continual dissolution of the metal in the electrolyte. This is controlled by the choice of the electrolyte. A third feature is the ability to endure continual discharges. A properly designed arrester should have a life of several years. The design is, of course, largely influenced by the cost of the arrester. The results of an investigation of the resistance of earth connections is given in the fifth section of the paper. It was found that these could be considerably improved by saturating the ground with brine. The concluding part of this paper is a report on cement as a resister, prepared by R. H. Marvin. The specific resistance of different mixtures is from one to 3,000 ohms when wet; when dry, it is over a megohm; when again wet, the resistance falls to approximately its original value.

Ernest J. Berg presented a paper entitled "Tests with Arcing Grounds and Connections." This described a number of tests made on a twenty-five-cycle, 33,000-volt system supplied from a three-phase turbo-generator. The effects of grounding the system in various ways were examined, but no mathematical expressions for these were deduced. In one of these tests the high-potential side of a step-down transformer was grounded at both terminals and coupled with the high-potential side of a step-up transformer through a ground connection on one side and a spark-gap on the other. It was found that with this arrangement, when a discharge was taking place, the strains on the end coils of the step-down transformer were ten times normal at one end while apparently normal at the other. When the ground connection on the step-up transformer was removed, the strains were very much reduced. In another test an arcing ground was made at the terminal of the step-down transformer. It was found that the strains on the end turns at the grounded terminal were fifteen times normal. No abnormal strains were noticed at the other terminal of this transformer. Three transformers were then connected up in delta and an arcing ground established at one apex. It was found that the striking distance across the two transformers nearest to the ground was nearly double the normal, while that across the transformer opposed to the ground was twenty per cent above normal. Renewing one of the transformers so as to give an open delta grounded at one end produced very high stresses in the two transformers. In one it was fifty-five per cent above the normal; in the other, 2.2 times the normal. Grounding the middle line of the two transformers developed a stress in them of over two times the normal, and in each case the striking distance across the end coils was from fifteen to twenty times the normal. Placing an inductance in the grounding connection did not seem to affect the results, even though the reactance was twenty-five per cent of that of the transformer. Various methods of relieving these strains were investigated. One consisted in connecting condensers across the end turns, resistances being introduced in these shunts. This simply transferred the stress from the end coil to the next one. Loading the transformers did not materially affect the results. The author concludes that with increasing line voltages it will probably become desirable to resort to some new methods of protecting the windings of transformers and other apparatus connecting the high-potential lines. It is suggested that this might be accomplished by connecting a series of electrolytic cells in shunt with the end turns. He points out that in his experiments there were no transmission lines between the transformers, so that the results do not represent what would actually occur in a transmission system.

Percy H. Thomas, in a paper entitled "Critical Study of Lightning Rods on Taylor's Falls Transmission Line," discussed the two papers read by J. F. Vaughan and N. J. Neall at the May meeting of the American Institute of Electrical Engineers. These records are gone into in some detail and the lessons taught by them are summarized. They show that the extent of a lightning disturbance is readily extended over more than a mile or two and that it may charge up the line and send waves of static in both directions which are able to pass many miles and still cause arresters to discharge. It is thought that little protection is obtained from lightning rods located beside the line, and whether the protection is obtained from overhead or grounded wires or not depends entirely upon the arrangement of the wires and the frequency of grounding. Station arresters of the best types should, in the absence of severe discharges close to the station, protect adequately the station apparatus if they be properly insulated. Horn arresters, as installed, are not nonarcing without adequate series resistance, and can be relied upon occasionally to shut down the plant. Both the electrolytic and the low-equivalent arresters showed themselves properly non-arcing and caused no trouble on this score.

The discussion was opened by the reading, by P. H. Thomas, of a communication from J. F. Vaughan discussing Mr. Thomas's paper. Mr. Vaughan said there was little evidence of there being much energy in a lightning discharge, provided the successive discharges succeeded one another frequently. If one accepted the release of the bound-charge explanation offered by Mr. Thomas it would be necessary to modify our ideas concerning the effects of lightning. As indicating the value of the grounded wire, the experience with a three-phase system arranged in the usual triangular manner offered some evidence. It was found that with such an arrangement the wire facing the direction in which a storm was coming was the one to suffer first; while, as the storm passed over the transmission line, the wire at the top showed the greatest activity. In his investigations he had not noticed any direct strokes.

Dr. C. P. Steinmetz expressed his appreciation of the value of these painstaking investigations of lightning troubles. The study of transient phenomena such as lightning is exceedingly valuable, and it seems likely that before long we will be as familiar with such phenomena and be as able to predetermine their effects as we can now for ordinary alternating currents. Coming to the ground wire as a means of protection, with the exception of a few "doubting Thomases" this is now generally admitted to be the most efficacious protection. Dr. Steinmetz does not agree with Mr. Thomas's explanation of the Taylor's Falls trouble. The latter says the cause of the trouble is not a direct stroke, but the releasing of a bound charge, and Dr. Steinmetz can not see the difference between the two. Regarding the use of tell-tale papers, it would be well to fireproof these by the use of some such material as tungstate of sodium, which would prevent combustion after a discharge. This treatment in no way affects the paper nor changes its behavior with regard to the discharge through it. It simply prevents its continuing to burn.

P. M. Lincoln agreed with Dr. Steinmetz concerning the value of the grounded wire, and took issue with Mr. Thomas in his interpretation of the records given in Mr. Vaughan's previous Institute paper on the Taylor's Falls experiments.

Dr. A. E. Kennelly said the construction of an overhead line was important on account of the change in construction involved when such is used. As to its benefits, the experience of half a century in telegraph operation seemed to be of value. Although the conditions of operation and the troubles resulting from lightning on telegraph systems were different from those on transmission lines, it still was significant that the lower telegraph wires always escaped during thunder-storms. This had led to the use of a short grounded wire run up each pole as a means of protection. Nevertheless, it is not safe to hope for perfect freedom from trouble, nor is it time yet to form a definite opinion of the cause of the disturbances. There are several possible causes, and our minds should be held open until more definite and complete knowledge is obtained. There is one cause not usually recognized. This is the electromagnetic waves set up by a distant lightning discharge.

J. B. Taylor objected to the use of the term "lightning" in a broad sense, a use attributed to Dr. Steinmetz. There seemed to him no reason why the old meaning of the term should be changed. Regarding the frequency of the discharges as found in Mr. Creighton's investigation, he wished to know whether the lower frequency was not merely the natural discharge frequency of the line. Mr. Berg's experiments were valuable, but, unfortunately, no explanations of the effects there described were attempted.

Mr. Taylor also asked what authority Mr. Thomas had for his use of the term "static" in a new sense, particularly since the electrical charge referred to was one in motion.

R. H. Marriott described some experiences which he had had with electrical disturbances on a wireless telegraph antenna. Three kinds of disturbances were noticed —electromagnetic waves, such as referred to by Dr. Kennelly, produced by a distant lightning discharge; a direct discharge to the antenna, and disturbances produced by wind friction on the wires.

D. B. Rushmore cautioned the Institute against drawing conclusions from insufficient knowledge. More complete investigations must be made. In his opinion the application of the oscillograph to the study of lightning phenomena was the first real step which had been made in this direction. He did not think that a burned hole in a piece of paper could be taken as real evidence. It is only a "may be." The ground wire is generally accepted as good protection, but it is hard to prove directly its value. He thought the proper method of protecting a system is to install lightning arresters to protect the station apparatus, but not the line. To protect the latter an overhead ground wire or lightning rods should be used, and better line insulators. We are now at the point where we are able to protect the station apparatus against lightning troubles, so that the problem is being transferred from the station to the line, and here the study of line insulation is the most important question.

J. W. Fraser explained briefly the experiences of the Southern Power Company in the use of lightning arresters for protecting its transmission lines. Both multigap arresters and low-equivalent arresters are employed. Last fall a number of aluminum arresters were put in. Since then several severe storms have occurred, and the latter arresters seem certainly to be doing good work. They handled three severe grounds without damage. During last season the Southern Power Company lost but one transformer, and that one had been damaged somewhat during erection. There were a few broken bushings, indicating that a better passage to ground was necessary at certain points.

L. W. Waters took up Mr. Berg's paper, saying that if the potential at the end turns of a transformer increased toward the end, the excess potential of the last turn might easily be 100 times the normal at times of lightning troubles. If taps are introduced these simply add danger points. The only solution of the problem thus confronted is extra insulation of the end turns or the use of choke-coils. On account of the expense of the former method the latter is the only one commercial. He thought that probably the conditions are not quite so serious as Mr. Berg's paper makes out, as records of performance do not indicate that the end turns are more liable to trouble than intermediate turns.

William McClellan said that the telltale paper records should be taken merely as corroborative evidence. The method employed by Mr. Creighton is good as giving direct evidence. There are two parts to this problem—the protection of the station and the protection of the line. We are able now to protect the former, and the question is merely the amount and kind of protection to be adopted. The great problem, therefore, is to protect the line. It is impossible to do this with the station arresters, and the best solution seems to be the grounded wire.

F. Osgood asked what the limits of the disturbing influences during lightning troubles are. He also wished to know what is the value of serving the wire at the insulators so as to prevent breakage due to arcing.

D. C. Jackson thought that not enough work had yet been done in investigating lightning troubles to lead to entirely satisfactory conclusions. To-day it is merely a question of how much money a system can afford to spend to protect its lines. He is looking forward to better results in the future.

Dr. Steinmetz, replying to the question asked by Mr. Osgood, prompted by a conclusion drawn in Mr. Thomas's paper, said that that conclusion must not be accepted too literally. The statement that the effect of discharge is limited to only half a mile is not quite true, since even though the direct discharge does escape to ground within this distance, the secondary effects, such as surges, may extend over the entire line. He did not agree with Mr. Waters's statement that there was no evidence of abnormal stress on the end turns of transformers, because the continued breakdown of the end turns had forced the manufacturers to increase the insulation of these turns. Now the fact that there is no more trouble there than at other turns is merely an indication of the proper distribution of insulation and of correct design. Very high-potential transformers, however, still give trouble there.

In closing the discussion on his paper Mr. Creighton said that there were no dynamic currents on the line when his records were taken. He did not think that overhead grounded wires afforded complete protection, but they bring the potential of the system during the disturbance to a value which the line can stand. Storms vary considerably, but are largely influenced by the country. Regarding the broad use of the term "lightning" he placed the responsibility on Dr. Steinmetz, but thought this use good. As to the frequency of lightning discharges, it is hard to say. These may have almost any frequency, as high even as a million cycles per second, or no frequency at all, being simply a single discharge. He agreed with Mr. Berg that the greatest problem is to protect the system against internal surges. One important question is how many stations must be fitted with arresters to protect them all against these troubles.

Mr. Berg, replying to Mr. Taylor's criticism, said that no theory of the arcing ground can yet be given because the knowledge is incomplete. He found that during these troubles the end turns of the transformers are heated, indicating the flow of a heavy current there. Choking-coils are not completely effective for protecting transformers, and the General Electric Company insulates the end turns of its transformers for from 100 to 200 times the normal voltage.

P. H. Thomas said that caution should be used in studying Mr. Berg's results. His records are given in the distances jumped by the sparks, and not in the actual potential of the discharge. He himself objects to the wide use of the term "lightning," but thinks the term "static," as used by himself, fits the case exactly. His views on the value of the grounded wire seem to be misunderstood. He thinks that this does give the best protection, but his criticism of Mr. Vaughan's conclusions was that the evidence which the latter gave does not show that the grounded wires installed on the Taylor's Falls transmission lines gave the protection attributed to them. In his opinion there is a difference between a direct stroke and the release of a bound charge, and the means for handling the two disturbances should be different. The thing is to determine which of all the troubles is the damaging one. That can then be taken care of and the others let go. Replying to Mr. Osgood's question, he said that the effect of the direct discharge is limited to a comparatively short part of the line, but there may be a series of discharges taking place within one neighborhood. He differed with those who objected to the drawing of inferences from experiments, even when incomplete. In his opinion this is the only way in which to advance rapidly.

J. W. Fraser read a paper on "Some Engineering Features of the Southern Power Company's System." This calls attention to the large number of cotton mills situated in North and South Carolina within transmitting distance of certain large water powers. The opportunity thus offered has been seized by the Southern Power Company, which has secured ten water powers aggregating not less than 150,000 horse-power. It is estimated than the mills lying within the district of this company use approximately 200,000 horse-power, which costs them to produce on an average about $34 a year. In one or two cases the cost had been reduced to $30. Mr. Fraser then discusses the system selected by the Southern Power Company. The original plant on the Catawba River, with an output of 10,000 horse-power, was operating at sixty cycles, and a large number of the motors in use in the mills were, of course, for the same frequency. While a certain economy might have resulted from the selection of a different frequency, it was thought that, on the whole, the most economical solution would be to retain the old frequency. The voltage selected was 44,000, which was sufficiently high for the district covered, and was less expensive to install than a higher potential. The line construction, station and substation equipments are described and the reasons for installing a reserve steam station are explained. It was found at one of the plants that the minimum power was 16,000 kilowatts and that there was an increase of 2,000 kilowatts. If secondary power were to be developed for eight months, the total output could be 24,000 kilowatts. It is a question how much of this secondary power can be developed economically in a steam plant. By charging this power with the entire cost of the steam equipment, it was found that the maximum profit would be made when 2,200 kilowatts in secondary power were developed, but since the steam plant really serves as a reserve for the hydraulic system, it seems only fair to charge the latter with the cost of this reserve and to charge against the secondary power only the actual cost of producing it. On this basis it would be profitable to install a secondary station with an output of 5,500 kilowatts. For these reasons it has been decided to install an auxiliary plant to develop fifty per cent of the primary power.

The discussion was opened by J. H. Finney, who directed attention to the excellent constructive work being done by the Southern Power Company. The character of the load there makes reliability very important, and for this reason only conservative construction is adopted. A high character of work has been followed throughout the entire installation, and he believes that the system as a whole is as creditable as any in the country.

D. B. Rushmore also praised the character of the work being done by the Southern Power Company, which, he said, was unusually creditable. The 44,000 volts adopted as a maximum there was conservative when first selected, and the importance of the system did not permit any risk to be taken. He thinks that at present there is no justification for a good many of the high potentials which are being adopted. He suggested that multiples of 1,100 volts should be taken as standards, and gave the following list of suitable values: 6,600, 11,000, 22,000, 33,000, 44,000, 66,000, 88,000, 110,000 and possibly 165,000. He believed, however, that to-day there is no reason for anything less than 110,000, except for very conservative systems. The 88,000 might be left out. The Southern Power Company's system has been designed for at least 66,000 volts, so that for a 44,000-volt system the factor of safety is unusually high. There is today no reason for using a high-tension delta-connected system, because such a system can not operate with one wire down nor with one transformer cut out.

P. M. Lincoln said that while standardization before adoption is advisable, it would hardly be wise at this time to drop 88,000 volts as a proper transmission potential, because there are now a number of systems going into operation which have adopted this voltage. The selection of a delta or Y-connected system depends upon whether it is intended to operate with a grounded neutral or not.

W. S. Lee, Jr., said that another condition had arisen which might alter the Southern Power Company's decision regarding the development of secondary power. There are a number of cotton mills having highly efficient steam plants, but which would use electric power for six months if they could thereby effect a saving. Hence the company is planning to install sufficient equipment to supply this demand during the months of high water. He said also that in the selection of the voltage of the Southern Power Company the company had in anticipation the use of 88,000 volts later on, and for this reason the insulation of the lines had been particularly cared for. Replying to a question regarding the simplicity of the wiring of one of the generating stations, Mr. Lee said that there were to be three plants in that immediate neighborhood for which there would be but one large complete switching station.

Dr. Steinmetz commended the conservative selection of potential and of line construction adopted by the Southern Power Company. He said that the great results in electrical development which had been accomplished in the South were remarkable. It is noteworthy that the conditions existing there are very different from those in the West. On the Pacific Coast cheap power is very important. In the South there are many efficient steam plants with which the transmission plants must compete, and the character of the load, which is mainly cotton factories, is such that reliability is absolutely essential.

Austin Burt read a paper on "Three-Phase Power Factor." According to the commonly accepted definition of power-factor as the ratio of true power to volt-amperes, there is no single factor which will exactly express such a physical relation in a delta-connected unsymmetrical three-phase system. It is possible, however, to determine by practical methods the weighted mean of the three power-factors of the single-phase pairs of such a three-phase system and to express that value by a single factor. The power-factor of a system may be taken as the cosine of the angle whose tangent is the ratio between the wattless ampere-volts and the energy ampere-volts. The ratio of the total energy-ampere volts and the total wattless ampere-volts in a three-phase system gives a value which is the weighted mean of the similar ratios of the several single-phase pairs. The cosine of the angle whose tangent is this mean ratio may be taken as the mean power-factor of the system. The author then derives the expressions referred to and shows how a polyphase wattmeter may be utilized for measuring the quantities necessary to give the desired ratio by disconnecting first one of the pressure wires and then the other.

C. A. Adams gave a simple non-analytical method of proving that two wattmeters may be employed for measuring the true power of a three-phase system. This conclusion is reached by treating one of the wires as a common return for the other two, considering the whole system as a two-phase system without respect to the difference in phase displacement. He asked whether his solution were not rigorously true.

Dr. F. Bedell said that the proof was rigorous, and had been given by A. Blondel in his paper read before the International Electrical Congress at Chicago, in 1893.

This completed the morning session, which was then adjourned.

TUESDAY EVENING SESSION.

The Tuesday evening session was called to order by President Stott at 8 o'clock, and three papers dealing with high-potential problems were taken up.

Ralph D. Mershon, in a paper entitled "High-Voltage Measurements at Niagara," described the results of tests on an experimental line which had been carried out more or less continually from 1903 to 1907. An experimental line having a total length of 2,000 feet was erected, supported on wooden poles 140 feet apart. The wires were supported first on insulators and later on paraffin cords attached to the insulators in order to eliminate effects of insulator leakage. In addition to the longer line, a short line, a few feet in length only, built up of cross-arms, pins and insulators, was constructed so as to enable the insulator losses to be studied without bringing in losses through the air. Aluminum conductors of various sizes and one copper conductor were tested. The apparatus and methods of measuring the losses are described, the usual method being to balance the two transformer losses against each other, thus enabling the loss taking place, due to the line only, to be measured directly. The general conclusions deduced from this investigation are: With a given conductor at a given spacing, under given atmospheric conditions, there is a certain voltage or critical point at which a very appreciable loss begins to occur through the atmosphere. There may or may not be a loss below this critical point, depending upon the atmospheric conditions. Floating particles in the atmosphere, whether of moisture or solid, promote such loss, and also increase the loss above the critical point. This critical point corresponds to a partial breakdown of the dielectric and coincides with the voltage at which luminosity or hissing of the conductors begins. It depends upon the maximum value of the electromotive-force wave and the distance between conductors. It is really fixed by the potential gradient at some point in the atmosphere. There is a loss over insulators which is affected by the moisture conditions of the atmosphere. The variations in the atmospheric and the insulator loss, due to atmospheric conditions, bear a definite relation to the product obtained by multiplying the vapor pressure by the relative humidity. So far as is at present known, this relation is empiric. The loss over insulators during a fog is higher than in dry air or during a heavy rain. The smoother the surface of the conductor the less the loss, while stranding conductors decreases the loss, due to the increased equivalent diameter of the conductor. Weathering of conductors does not apparently affect the critical point. This point is the same for copper and for aluminum. Anything which increases the charging current of an insulator increases the loss of an insulator, and this loss is greater when wooden pins are used than when the pins are of metal because of the greater resistance of the wooden pin. These losses decrease with the frequency, but the law of decrease is not yet known. Neither the critical point nor the loss between cables is affected by variation in the distance of the cables from the ground.

Following the presentation of this paper, Dr. Samuel Sheldon, in an appreciative address, presented, on behalf of the board of directors of the Institute, engrossed resolutions to Charles F. Scott in acknowledgment of the work which Mr. Scott had done in securing Mr. Carnegie's gift of the Engineering Societies Building and also for Mr. Scott's valuable work as one of the Institute's trustees of the United Engineering Society.

Mr. Scott was deeply touched by this tribute and appreciation, and expressed his feelings warmly.

The discussion on Mr. Mershon's paper was opened by the reading by P. H. Thomas of a communication from H. L. Doherty which discussed the great value of such high-voltage studies.

Dr. Elihu Thomson then took up Mr. Mershon's conclusions *seriatim*. The first conclusion that there is a certain critical voltage is well known. The second is somewhat remarkable, as this states that there may be a loss below the critical voltage depending upon the weather, though there is no visible indication of such loss. The third conclusion, which states that particles in the atmosphere may produce such a loss, is perfectly logical. The effect of water vapor in producing a loss below the critical point may be explained by the fact that water vapor just above the condensation point is not a true gas. There are then some particles of water in the liquid condition. This view brings conclusions 3 and 4 together, and from this conclusion 5, which states that the presence of moisture affects the amount of loss above the critical voltage, follows logically. That the presence of moisture and other particles in the atmosphere affects the position of the critical point is explained by the fact that such particles extend the influence of the conductor.

The next five conclusions, which state that the critical point corresponds to a partial breakdown of the dielectric and coincides with the voltage at which luminosity begins; that this point depends upon the maximum value of the electromotive force; that it depends upon the distance between the conductors and their diameter, and that there is a loss at the insulators which is affected by the atmosphere, are all admitted. Mr. Mershon had apparently found a law connecting atmospheric loss with the product of the vapor pressure by the relative humidity. This is natural, since the quantity of moisture and its condition are both concerned. The greater loss due to fog, as compared with rain, may be because in the former case the entire insulator is covered with water. The conclusion that the smoother the surface of the conductor the less the loss seems logical, but it does not agree with the next two conclusions, which state that the use of a standard conductor of equivalent diameter reduces the loss. The weathering of aluminum conductors would not be expected to increase the loss, and it is also to be expected that this loss would be independent of the material of which the conductor is made. That the increase in the charging current of the insulator increases the loss is natural. The same is true of the conclusion that this loss decreases with the frequency. The fact that the distance from the ground does not seem to affect the loss may be because this distance is relatively very much greater than the distance between the wires.

Dr. Samuel Sheldon called attention to the study of the atmosphere which has been made by Professor Carl Barus, of Brown University. Investigations have been made at Providence, R. I., and at Block Island. He has always found that ions are present in the atmosphere at both places. Dr. Sheldon explained Professor C. T. R. Wilson's idea of how ionization takes place. It is due to the collision of a rapidly moving ion with a molecule. This collision splits another ion off the molecule, which, in its turn, may cause ionization of a second molecule. The effect, when once started, spreads rapidly like a conflagration. Hence the comparatively sharply defined critical voltage.

Henry Floy discussed the early experiments of Professor H. J. Ryan, on atmospheric losses, and said it is probable that the different values of the critical voltages as found by Ralph D. Mershon and Professor Ryan were due to the different methods of determination. Professor Ryan had depended upon visual observations, while Mr. Mershon had used instruments.

Dr. Steinmetz does not admit that the critical potential indicates a sudden change. The change must be gradual. The discharge would probably be started at the kinks in the wire, where brush discharges will arise. They do not represent the true critical potential of the wire. It is hard to get accurate results. He suggested that if Mr. Mershon would plot his results on logarithmic co-ordinates, thus getting straight lines, instead of the logarithmic curves he apparently obtains, that it would be much easier to extend these lines, and thus obtain the critical value accurately. The results given in the paper show that there is a loss, but more work must be done before its value can be known accurately.

P. H. Thomas said that at the present time these atmospheric losses are negligible from a commercial point of view. He suggested also that a quadrant electrometer might be used advantageously for measuring the energy of these losses, since but little energy is consumed in this device. He asked for data indicating the actual atmospheric loss during rain.

P. M. Lincoln pointed out the fact that the experiments had been conducted on a single-phase line, and since the relative potential of the line to ground of a three-phase system would be different, the results might not be directly applicable to the latter.

C. F. Scott said that laboratory experiments frequently failed to give results applicable to outside conditions. This atmospheric loss determines the limit of potential which may be employed for power transmission, and he asked how the limits as found by Mr. Mershon in his recent investigation agreed with those which the latter had assumed in an earlier Institute paper, in which the statement was made that the economical size of conductor for any length of transmission and any possible potential would bring the system below the critical potential.

P. N. Nunn thought that the subject

was more of scientific interest in its present form than of practical value. What is needed on a transmission system before all else is reliability. The insulation of a system must be considered as a whole, and the loss as due to its weakest links. He gave briefly an account of a number of systems with which he had been connected, which had given various degrees of satisfaction, and not always in proportion to the amount of protection or the expensiveness of the installation employed. The best lines have frequently given trouble, and the cheapest ones have been immune from it. Why, he could not say.

Dr. Elihu Thomson questioned the accuracy of the statement that the increase of loss due to vapor in the atmosphere is the same for the same vapor product, no matter what the size of conductor or what the spacing between conductors.

In closing the discussion Mr. Mershon said that undoubtedly Professor Ryan's high values for the critical potential were due to his method of determination. The latter depended upon the appearance of luminosity. Referring to Dr. Steinmetz's criticism, he said that even though the wire might have been kinked, the conditions obtaining were those of actual construction. He questioned whether Mr. Thomas's suggestion that a quadrant electrometer be used could be adopted, because of the loss taking place in the wire employed for splitting the potential. Readings of atmospheric loss during rain had been taken, but no consistent values had been obtained. The behavior then resembled that during a snow-storm. Mr. Lincoln's point regarding the difference between a single-phase and a three-phase system with respect to the ground was good, but this point had not been taken up, and nothing had been done as yet to determine the losses of a three-phase system.

D. R. Scholes presented a paper entitled "Fundamental Considerations Governing the Design of Transmission Line Structures." Before a tower or pole for a given transmission line can be designed, some conclusion regarding the loads to be borne must be reached. Since the towers now in use for transmission lines resemble closely windmill towers, it seems that the best guide in selecting figures to represent the problem of extreme load conditions may be gathered from a study of such structures, as they are the result of many years' experience. The various factors then affecting the strains on the towers, such as wind, sleet, low temperature and accidents due to breaking cables, etc., are considered. The author suggests that towers be designed to resist a wind pressure of forty pounds per square foot, with a factor of safety from one and one-half to two. The actual value of this factor is to be determined by experiment, and the method suggested is the erection of an experimental span as near as possible to a weather bureau station, provision being made to measure the stress. The figure of thirty pounds per square foot is commonly used in bridge calculations, but it is unsafe to assume this in localities where high winds prevail, and when it is used a factor of safety of two should be adopted. It is suggested that the structure should provide for a coating of sleet at least half an inch thick, a factor of safety of two being employed in calculating the ultimate strength of the conductor to carry this load. To insure the cross-arms against breaking, should a cable give way, it is suggested that the arms should be tested to loads equal to one and one-quarter times the elastic limit of the conductor if on pin insulators, and one and one-half times the elastic limit of the conductor if on suspension insulators. In developing the design of the foundation for a given line, tests should always be made to determine the holding power, density, etc., of the soil so that the strength of the foundation will be known as accurately as the strengths of the other parts of the line.

A communication from N. J. Neall was read by Mr. Thomas, which criticized some of the suggestions made by Mr. Scholes, and suggested that more conservative figures would be better, and that a factor of safety of two should be the least employed at any point.

C. E. Skinner presented a paper on "The Testing of High-Voltage Line Insulators," in which a specification is proposed as standard for the testing of high-voltage line insulators. This specification was prepared by request of the High-Tension Transmission Committee of the Institute and it represents, as far as possible, the harmonized information obtained from different sources, and not Mr. Skinner's personal opinion. The specification is divided into three parts: Routine tests, such as inspection, dielectric tests; design tests, for determining the mechanical strength, whether the insulator will be able to withstand its full potential, rain tests and dew tests, etc., and, finally, instructions for carrying out the various required tests. Some of the requirements of these tests, such as the rain test, are more severe than would ever be experienced in practice except under the most unusual conditions.

A communication by N. J. Neall, discussing this paper, was read, in which more severe tests are urged. At least three times the normal potential should be applied to every insulator. Objection is also raised to the suggested method of making the rain test. Mr. Skinner proposes placing the insulator at an angle of forty-five degrees and allowing the water spray to fall vertically. Mr. Neall contends this will not represent the actual conditions on account of electrostatic and gravitational forces.

P. H. Thomas said that insulators should be tested by means of a spark-gap so as to produce a high frequency, and asked what provision has been made for testing at different frequencies.

Mr. Mershon approved the use of the vertical spray with inclined insulator because of the difficulty of accurately obtaining a specified spray at an angle. There is also a good deal of trouble in finding exactly what the spray shall be. He thought that the amount of precipitation recommended was too small. That usually required is one inch per minute, and the records of the Weather Bureau show that occasionally 0.8 inch falls during an actual rainstorm.

Dr. C. H. Sharp described a spray which is used abroad, and which he purposes using in this country for testing insulators. This consists of a cylindrical tank, in the bottom of which are a number of small tubes, each plugged with asbestos wool or some similar material. By applying air pressure to this tank any rate of precipitation desired may be obtained, while this may easily be measured by means of the gauge glass on the tank.

E. M. Hewlett suggested that a steam test might be better than a rain test.

Dr. Steinmetz suggested that all insulators should be submerged for one week before applying the test. This would allow any absorption of moisture due to the appearance of hair cracks in the glaze to take place. Such absorption will, of course, take place after the insulator has been installed. He did not think it was advisable to test any insulator at less than twice the normal potential.

In closing the discussion Mr. Skinner said that in his opinion a dew test will be more severe than a rain test, and much easier to reproduce. He did not think that accurate results could be obtained by blowing the spray against the insulator. The specifications which he had proposed were intended to indicate what a performance test should be and to draw out further information.

The session was then adjourned.

(To be concluded.)

Street Railway Association of the State of New York.

Twenty-sixth Annual Meeting, Held at Niagara Falls, Ontario, June 30 and July 1.

THE twenty-sixth annual meeting of the Street Railway Association of the State of New York was held at the Clifton Hotel, Niagara Falls, Ontario, June 30 and July 1. President T. W. Wilson, general manager of the International Railway Company, Buffalo, N. Y., called the meeting to order at 10.30 A. M., June 30, in the assembly room of the hotel, and introduced the Hon. R. F. Carter, mayor of the city of Niagara Falls, Ontario, who welcomed the railroad men to the city and voiced the appreciation of the city officials upon the selection of Niagara Falls as their convention place.

The secretary made several announcements, and, on motion, the reading of the minutes of the last meeting was dispensed with.

President Wilson then delivered his annual address, saying that while the beginning of the year pointed to a most prosperous era, since last October there has been a struggle to reduce operating expenses commensurately with the falling off in gross earnings. Ninety-eight per cent of the total earnings of electric railways is derived from receipts from passengers and consequently the electric railways had not suffered as heavily as the steam roads. He reviewed the work of the association during the year and commented particularly upon the work of the Committee on Standard Classification of Accounts.

The secretary, J. H. Pardee, reported that the number of active members had remained the same during the year. Three allied members had resigned and twenty-two new allied members had joined, making a total of 100 allied members. William Sharpe and J. C. Calisch, who were elected at the last convention as members of the executive committee, were compelled to resign on account of business engagements. E. J. Cook, of Rochester, and R. J. Dyer, Jr., of Auburn, were elected to fill the vacancies.

The next item of business was the report of the treasurer. H. M. Beardsley, secretary and treasurer of the Elmira Water, Light and Railroad Company, presented his report, showing total receipts for the year amounting to $10,875.23; expenses, $6,897.05; balance, $3,978.18.

C. Loomis Allen, of the Syracuse Rapid Transit Company, presented the report of the Committee on Classification of Accounts. This report indicated that it was unsatisfactory for the street railway companies and the steam railroads to make up their accounts on the same classification. Another objection was the incorporation of a theoretical depreciation account in the classification. Still another was the keeping of such a large number of primary accounts as were called for for the electric railways. After the committee had worked with the Interstate Commerce Commission and the Public Service Commission, a final classification of accounts was submitted which had been approved by the Interstate Commerce Commission, and will be promulgated on October 1. The resulting classifications were three in number, known as A, B and C. Classification A is kept by all roads having gross receipts of more than $250,000; classification B is kept by all roads having gross receipts between $50,000 and $250,000; classification C is kept by roads having receipts of $50,000 and less. The electric railways succeeded in convincing the regulating commissions that it would not be to the best advantage for electric railways or commissions to insist that steam and electric railways should account upon an identical classification.

Concerning the question of depreciation it is stated that the Interstate Commerce Commission in its classification will not promulgate depreciation, but will depend upon the second year upon what a majority of the state commissions will do with the classification as to whether they shall incorporate it in the order for the second year's operation.

In presenting the report of the Committee on Electric Express and Freight Service Mr. Allen stated that W. C. Collins had carried on most of the work in connection with this report. The committee had held four meetings. At the first meeting Mr. Collins was elected secretary, and since that time the bulk of the work had devolved upon him. There had developed, however, several matters which he would call upon the members of the committee to talk about. These were the question of rates and the question of blanks. He asked A. Eastman to deliver the report upon the question of rates.

Mr. Eastman stated that possibly no uniform or standard form should be adopted in compiling express and freight rates. He believed, however, that it would be to the interest of all electric railway companies to adopt a uniform tariff sheet, if for no other purpose than to make the filing with the Public Service Commission more uniform and standard. Any comparison of figures concerning the freight rates established by different companies would be very misleading, and would indicate that the company having a few miles of track was getting a much higher rate per ton-mile than a company with considerable mileage. This results from the fact that a five-mile haul at a rate of ten cents per hundred gives a rate of forty cents per ton-mile, when possibly the same commodity would be hauled fifty miles at a rate of twenty cents per hundred, giving a rate per ton-mile of eight cents; while if the five-mile rate were taken as a basis, the fifty-mile haul would amount to ten times as much as a five-mile haul, or $4 per ton-mile. It can therefore be clearly seen that the length of haul controls the rate per ton-mile. A number of the electric railway companies have adopted a minimum charge of ten cents per shipment, but unless competition is such that it is absolutely necessary to do so, the author did not think that the minimum charge should be less than fifteen cents per shipment, and it should be twenty-five cents when possible.

There was no discussion upon this section of the report and W. C. Collins was called upon for his comments.

Mr. Collins suggested that the best results could be accomplished if a considerable amount of standardization should be done in order to evolve a system that should be sufficiently elastic to cover all roads and all conditions. An important point to be taken into consideration is the difference in operation. A city company operating with an express messenger on a car would not need such an elaborate system as a large interurban road operating through towns with agents. It is just such cases as these that it is necessary to harmonize. The primary blanks would be the same, however, for all companies. He then described the blanks which would be needed to carry out the different functions necessary under different regulations of service.

Edgar S. Fassett, general manager of the United Traction Company, of Albany, N. Y., stated that there were several points which should be taken into consideration concerning the Interstate Commerce Commission. He said that, judging from the most recent decision of the courts, any freight or express which is consigned to points outside of the state or which comes from points outside of the state and is consigned to a freight or express company, brings the electric railway company under the Interstate Commerce act, with all its conditions. He has recently issued an order making it impossible for his company to accept freight and express consigned to points outside of the state or to receive from any steam railroad any freight or express coming from outside of the state.

The next report was by A. R. Walsh, of the Schenectady Railway Company, on the question of freight and express departments. Mr. Walsh considered that the total operating expenses per car-mile for carrying freight varied from twenty cents per car-mile to $1.02½ per car-mile. In averaging these costs it was discovered that the company that operated for twenty cents per car-mile earned a gross of forty-four and one-half cents per car-mile, while the company that operated for $1.02½ per car-mile earned in gross a fraction over $1.28 per car-mile. The company with the operating expenses of $1.02½ per car-mile earned one and one-half cents net more per car-mile than the company which operated for twenty cents per car-mile.

There was a large variation in the mileage—196,602 miles for one company, against 30,515 for the other. The one company in ten months earned almost $50,000 gross more than the other, while the expenses were only about $8,000 more. What makes the cost of operation vary so in this particular case is the vast difference in mileage.

One company operated for thirty-three cents per car-mile, and earned net about seventeen and one-quarter cents per car-mile. Another company operated for seventy-three and three-quarters cents per car-mile and while it earned gross eighty-one cents per car-mile, it only earned net about six and one-half cents per car-mile. Neither of these companies did any delivering by wagon, both of them handling nothing but freight; consequently, they had no stable expenses to figure in.

There is no doubt that the express and freight service on electric lines is a great convenience to the merchants, as it is possible for them to get quick service at times when they find themselves short of some particular article. It enables them to carry a smaller stock, and the result is that the electric roads get a large number of shipments.

High charges against the freight department are not right. Taking a freight car and a passenger car of equal weights and equipment, on a twenty-mile run the consumption of power by the freight car will be considerably less than that of a passenger car.

It has been said that an arbitrary charge per mile should be assessed against the freight and express cars. This might be all right if the freight and express privileges were leased to another company, but where the railway company is doing the work itself or where it has a separate department, it would seem that a proportion of the operating expenses should be charged.

Where the companies carry freight in combination cars the costs, of course, decrease.

The author considers that where freight and express is given a proper chance it will be found to be a profitable business.

Mr. Allen moved that the incoming president should appoint a new committee upon freight and express to continue the work for another year. This motion was carried.

The report of the Committee on Height of Car Steps was presented by E. F. Peck, chairman.

The report stated that the committee had held several meetings and that, in so far as the question immediately related to cars now in use, it had been unable, on account of the greatly varying conditions found on many roads, to come to any decision which would be of practical value, as it was very evident that at least the roads which have been represented at the meetings had individually given the matter careful consideration, and had not been able to arrive at any definite conclusion.

The report rehearsed the evolution of the electric street railway from the days of the horse-car, and indicated how the problem was involved by the matter of the spacing of the centres of the tracks.

In the case of closed cars it had been possible to keep within limits which seemed to be reasonably convenient for passengers generally. The committee felt warranted in making the recommendation that in the design of cars to be built in the future for use in cities, the height and rise of steps be, measuring from the top of rail, not more than seventeen inches; from step to platform, fourteen inches, and from platform to floor of car not more than ten inches. In no case did it consider the use of two steps from the street to the platform advisable.

In the case of double-truck, the width of track centres is the controlling condition. This limits the width of the car body, making it necessary to so design the steps that the truck frame, as well as the wheels, in swinging at curves, will have clearance under the step.

In the case of open cars so much depends upon the size of the motors, condition of roadway over which the cars run, as affecting the clearance above rails, and maximum allowable width of car, that the committee feels that perhaps the only reasonable recommendation which can be made is that in all cases the distance from the rail to the step be made as small as possible and the height from the step to the car floor be not more than seventeen inches.

In reply to an inquiry H. A. Benedict suggested that eight inches would be a proper width for a car step.

The report of the Committee on Model Car Repair Shop was presented by H. A. Benedict, chairman. This report gave elaborate details for a model car repair shop accommodating 100 cars. It is assumed that the site is a fairly level stretch of ground having a frontage of 570 feet and a depth of not less than 450 feet. Unprotected structural steel is at the mercy of a conflagration where wooden car bodies below or adjacent to it furnish fuel to distort and weaken the vital parts of the building. If reinforced concrete is used these risks are minimized, if not entirely eliminated. Brick is used for curtain walls which support only their own weight. A unit bay thirty-two feet wide from centre to centre of columns transversely and fourteen feet centre to centre of colums longitudinally is adopted. With the width of thirty-two feet the tracks may be placed on fourteen-foot centres, allowing nine feet from the centre of the outside track to the centre of the adjacent wall. This arrangement gives ample room between and alongside tracks. To secure proper lighting in the bays, which are entirely dependent upon overhead light, and to supplement such side light as may be secured from windows in the exterior walls, a uniform continuous skylight ten feet wide is placed in the roof of each bay on its axis. A car sent to the shop for repairs is switched to certain of the tracks and brought in over the repair pit. This pit is served by pit jacks and by two ten-ton electric traveling cranes in each bay. Each crane is equipped with two five-ton electric traveling hoists. If the car body needs either carpenter repairs or painting it is moved to an adjacent track in the bay and is lowered to a pair of shop trucks. It is then hauled to the carpenter or paint shop. For ordinary repairs the trucks are left over the pit where the car body was removed, and are placed in condition to receive the body after it has been returned from the paint or carpenter shop or another car body of the same type. Oil storage is provided in a separate building adjacent to the stock room. A brass foundry and foundry shop are provided adjacent to the forge shop. To afford efficient fire protection for the contents of the shops, a thorough system of hydrants, both inside and outside of the building, is provided. All hydrants are connected to a 25,000-gallon pressure tank at the rear of the property, as well as to the city water supply. As the buildings themselves are non-inflammable, no sprinkler system is recommended.

W. W. Cole thought that the location of the repair shop should be given very careful consideration. He has found that where repair shops are located at some point considerably out of town, it creates a very large non-revenue mileage in shifting cars to the shop. There is also a tendency to hold the cars too long before sending them to the repair shop, or a tendency to increase the amount of repairs done at the car-barns.

R. E. Danforth, general manager of the Public Service Corporation of New Jersey, said that in providing shops for scattered systems it is an open question whether a central repair shop is of material value. In New Jersey his company has to shift cars forty miles to a central repair shop. Where a well-designed division repair shop is provided it is often the case that the operating expense is less than on a division where a central repair shop is located. Each division master mechanic is particularly interested in the cost of operation of his particular cars, and never spends an unnecessary dollar upon a car when he gets it in his division shop. When he sends the car to the general shop for the annual overhauling he leaves as little as possible to be done at the general shop.

TUESDAY AFTERNOON SESSION.

The Tuesday afternoon session was called to order at 2.45 o'clock by Edgar S. Fassett, first vice-president.

The first paper was entitled "Commutating-Pole Railway Motors," and was read by E. A. Anderson, of the General Electric Company. This paper described the characteristics of the commutating-pole motor and indicated the advisability of adapting this type of motor to railway work. Replying to a question concerning the comparative cost of the commutating-pole motor, Mr. Anderson said that the extra cost of manufacture would probably be about twenty-five per cent. It was a question of increasing the reliability and buying that reliability as cheaply as possible.

There was no further discussion on this paper, and the session adjourned to make a trip over the gorge route and visit points of interest on the Canadian side of Niagara Falls.

WEDNESDAY MORNING SESSION.

The Wednesday morning session was called to order at 10.40 o'clock. The first paper was entitled "Observations on the Pay-as-You-Enter Car by the Mechanical Man," by W. H. Evans, master mechanic, International Railway Company, Buffalo, N. Y. This paper described the several forms of pay-as-you-enter cars which had been installed. In making an effort to reduce the weight of the cars and to simplify the operation of the equipment, particularly in connection with the pay-as-you-enter system, it is perhaps a very opportune time for railway companies to inaugurate equipment arranged for single-end service. With comparatively slight expenditure for necessary track arrangement which will facilitate the operation of cars on the single-end plan, a very decided improvement can be made in the reduction of the weight of the cars and in designing a stronger, more comfortable and a generally more satisfactory car than can be arranged for in double-end operation. The saving in the construction per car will easily offset the expense for the rearrangement of the tracks to permit single-end operation.

Attention was called to the Buffalo plan of fare collection. This arrangement consists of a fare box, or car safe, as it is called, with a suitable receptacle for receiving fares at the top, with a tripping device from which they are dropped into an inner cash box, where the fare is securely deposited until it is conveyed directly to the counting table in the treasurer's office. The small cash boxes are received from the treasurer's office unlocked, and in that position are placed on the inside of the car safe and receive all of the fares collected on the car from the time it goes into service until it is returned to the car barn.

Following the reading of this paper the meeting was addressed by Acton Burrows, secretary-treasurer of the Canadian Street Railway Association.

The next paper was entitled "The Pay-as-You-Enter Car from an Operative Standpoint," and was presented by C. A. Coons, superintendent of transportation, International Railway Company, Buffalo, N. Y. This paper described the method of instructing the trainman for handling passengers on the pay-as-you-enter car. The company has found that the car has become highly popular with both patrons and employés. Among the various advantages and merits of this type of car from an operating standpoint the following may be mentioned: Increase in revenues due to fares previously missed and otherwise appropriated, which are now dropped into the receiver and fare box; increase in speed due to cars being able to take on and discharge passengers simultaneously; decrease in regular cars operated, which necessarily decreases mileage as well as the number of car-hours; decrease in the number of accidents due to the presence of the conductor on the rear platform at all times; alleviation of conditions leading to jostling, crowding and other discomfort to passengers formerly caused by conductor pushing through to collect fares.

Duncan McDonald, general manager of the Montreal Street Railway Company, was introduced as the father of the pay-as-you-enter car. Mr. McDonald addressed the meeting very briefly upon the advantages of this type of car and said that his company was very well satisfied with its operation.

Mr. Danforth described the operation of the pay-as-you-enter car on the system of the Public Service Corporation of New Jersey. This type of car appears to suit the patrons very well, and in spite of the fact that it is of the single-end, cross-seat type, with a large rear platform, it has won the approbation of the people on the company's lines and eliminated all trouble and annoyance formerly caused by the conductor after the passenger had once entered and taken his seat. The company finds that it can carry almost as many passengers per car with some degree of comfort, and can satisfy a greater number of passengers on each car. There has also been an improvement in the collection of fares. After the company had installed the first fifty pay-as-you-enter cars it investigated the possibility of rebuilding some of its old equipment, and it has been found that some 250 or 300 cars were so nearly of the pay-as-you-enter type that an expenditure of about $200 per car will put them in shape for that method of operation. Other cars were found well adapted for double-end construction, and the company is now putting through its shops about 300 cars, some for single-end operation and some for double-end operation.

C. R. Barnes, of the Public Service Commission for the Second District of the State of New York, was introduced and asked for a discussion on the subject, "The Use of Curtains on Front End of Suburban Cars During the Daytime."

W. R. W. Griffin, of the Rochester & Eastern Railway, stated that his company always operated with the front end closed, one of the reasons for this being that it is often possible to carry express that the traveling public would not like to ride with. In this way the company increased its revenue. Another reason was that passengers on a high-speed car, especially in a hilly country, saw too many "near accidents."

Mr. Pardee stated that where cars were operated at a very high speed it was well to keep the curtains down, as the possibility and imminence of danger always impress the passenger when looking straight ahead of the car.

E. F. Peck, general manager of the Schenectady Railway Company, stated that on the Schenectady system the curtains were always up in the daytime. No trouble had ever been experienced. He thought that it made a much pleasanter trip for the passenger, and that in case the motorman was subjected to an accident or overcome in any way it gave the passenger and conductor a chance to see what was happening on the front platform, and in that way resulted in preventing a serious accident. Of course, at night the feature of the interference of the light is a serious thing, and it is then necessary to darken the front end of the car.

The next subject for discussion was "Some Practical Means to Enable Passengers Desiring to Board Trains to Stop Them at Flag Stations."

H. S. Williams, of the Utica & Mohawk Valley Railway, stated that his company provided a system of flag-stop signals consisting simply of a cast-iron switch operating five lights. This is manipulated by the passenger by means of a rope which is pulled at the time the car approaches. There is very little trouble in the maintenance of this signal. The lamps are lighted for only a small portion of the time, and burnouts amount to practically nothing. The box is made of wood, because the experience of the company has been that this stands up better than iron. The signal costs approximately $2.95 to build. This includes the entire cost of lamps, switches, sockets and everything else connected with the signal. The maintenance does not amount to over twenty-five cents a year for each signal.

Upon the suggestion of Mr. Barnes, a motion was carried requiring the incoming president to appoint a committee of five to investigate this subject and report.

The next topic was entitled "The Equipping of City Cars with Red Flags and Lanterns on Lines which Cross Steam Tracks at Grade."

Mr. Coons did not thing that it was a good plan to carry either red flags or lanterns on electric cars. If there was time enough to get out a red flag or a lantern to flag a train, there was time to get the passengers off.

Mr. Barnes did not think that the flagman employed at a steam-road crossing by the steam road affected the operation of the electric car in any way. He did not think that he was of any benefit in safeguarding the operation of the electric system.

Mr. Fassett was of the opinion that it would pay any electric railway company to have its own flagman at all places where a steam road crosses the electric road at grade.

Upon motion it was decided to refer this topic to the Rules Committee to report at the next quarterly meeting, if possible.

The next topic, "The Practice of Carrying Musical Instruments on City Cars," referred to the annoyance which is sometimes caused by the carrying of large instruments such as horns or drums upon crowded cars. The consensus of opinion appeared to be that it was the proper plan to issue either single permits or yearly permits, subject to cancellation if the carrying of the instrument proved an annoyance.

The paper entitled "Signals for Interurban and Local Traffic" was read by title.

Mr. Cole suggested that in view of the important work of the Committee on the Classification of Accounts, it would be well for the incoming president to appoint a committee of three to carry on this work during the next year. A motion to this effect was carried.

Mr. Cole extended a vote of thanks on behalf of the association to the retiring president for the very able manner in which he had conducted the work during the past year. President Wilson responded very briefly. He then called the attention of the meeting to the fact that Mr. Cole, who had been an active member of the association for many years, serving on its committees and as an officer, was retiring from the active management of an electric railway property which was a member of the association. It seemed fitting that a resolution should be spread upon the minutes electing Mr. Cole an honorary member of the association. This resolution was adopted unanimously.

The report of the nominating committee was presented as follows:

For president, E. S. Fassett, Albany.

For first vice-president, E. F. Peck, Schenectady.

For second vice-president, C. Gordon Reel, Kingston.

For secretary, J. H. Pardee, New York.

For treasurer, H. M. Beardsley, Elmira.

Executive committee: E. J. Cook, Rochester; R. A. Dyer, Jr., Auburn; J. W. Hinkley, Jr., Poughkeepsie; T. W. Wilson, Buffalo.

This report was adopted and the secretary instructed to cast a ballot for the ticket.

President-elect Fassett was escorted to the chair by Messrs. Cole and Cook. He addressed the meeting very briefly, stating his appreciation of the honor conferred upon him in his elevation to this position.

The convention was then adjourned.

Meeting of Lamp Testers.

A meeting of all the lamp inspectors in the employ of the Electrical Testing Laboratories was held in New York on July 6, 7 and 8. The following papers were presented and discussed:

"Visual Inspections of Electric Lamps," by C. E. Currier.

"The Best Procedure in Lamp Inspection," by C. H. Stephens.

"The Selection of Life Test Samples," by H. E. Allen.

"The Effect of Varying Test Quantity Upon Rejections," by W. F. TenEyck.

"'Bugs' in Photometry," by E. L. Peck.

"Lamp Inspections at Purchasing Companies' Storehouses," by W. J. Bray.

"The Criterion of Lamp Value," by A. W. Minty.

"The Value of Laboratory Tests," by W. H. Rolinson.

"The Functions of a Lamp Inspector," by George H. St. John.

"The Responsibilities of a Lamp Inspector," by L. J. Lewinson.

THE CONTRACTOR AND ILLUMINATION.

BY VAN RENSSELAER LANSINGH.

Ten years ago when a merchant contracted with a central station for electric light, he figured the installation purely from the standpoint of cost; so many lamps would be required of so much candle-power, and his monthly bill was forecast at approximately so much.

He bargained with the contractor in the same way and the question was: How much will it cost to wire my store for ten lights? The contractor gave his price on a molding job and on open cleat work and the customer took his choice. No mention was made of illumination and if plain drop lights were not used, fixtures and glassware were selected for price and not for efficiency. The central station representative suggested that the lights be placed so many in each window, so many along the counters, etc., and the contractor, when his figures were quoted, met the cry of "too much" with such advice as to rearrangement of outlets as he calculated would secure him the job. And so throughout the transaction the installation was considered merely so many electric lamps—not light, not illumination.

With the increasing popularity of electric light for residence, store and factory lighting, came a gradual and growing enlightenment on the subject; and the matter of efficiencies and economies in the various systems of artificial illumination became of general interest to the public.

As an outgrowth of and correlative with this development and the introduction of the various lamps of higher efficiency and scientifically designed globes and reflectors, has arisen a popular demand for accurate knowledge on the subject of illumination, resulting in the evolution of the profession of illuminating engineering. Also, the central station itself is giving more and more consideration to the subject, realizing that after all what the customer is buying is illumination, not simply current, and that it is incumbent on the lighting company to see that he receives full value for his money. So to-day we find a number of the larger companies with illuminating engineers regularly attached to their commercial staffs; working out efficient lighting schemes for new customers, and rearranging old installations to reduce cost.

The contractor, however, has not yet taken up this phase of his work to the extent which might be expected. The prosperity of the contractor and the volume of his business depend largely on the demand for electric current for lighting and the satisfaction of his customer in the results obtained from each installation. It is just as important to the contractor that every lighting system he installs should give the greatest amount of useful light, and be as economical as possible in consumption of current, as it is to the central station who reads the meter.

Many contractors have the idea that illuminating engineering is too complex and too large a problem for them to handle, taking the stand that the study of scientific lighting is outside their province and that they can not give the time necessary to mastering the subject. They sell motors, however, advising their customers without hesitation on matters of speed and drive, and the details of friction load and power-factor. Also when they give an estimate on a large generator set they do not hesitate to call on the manufacturer for assistance and the job is figured for them when necessary.

Just so, the more advanced problems in illuminating engineering may be handled on the advice of an experienced illuminating engineer; but the simple daily problems which the contractor encounters in the wiring of small stores, residences and factories require only a small amount of study, if it is backed up with a large amount of observation and plenty of good common sense. No highly developed technical education is necessary, but simply a thorough understanding of the fundamental principles of good illumination.

No contractor, nowadays, can succeed who considers his work to be limited to the mere screwing up of cleats and the stringing of wires. He must be part of the wave of development which is as broad as the country, embracing all who work in the field. He must be a co-operator. He must consider his work not "wiring for lights," but "wiring for illumination" and efficient economical results must be the end in view.

There are, of course, numerous instances where contractors large and small have already taken the broader view of the matter and are striving for efficiency. We cite only random cases, but they serve to illustrate the fact that those contractors who are to-day studying illumination and applying its laws in their work, are the farsighted forerunners of this inevitable development.

Frederick C. Ross, of 255 Greenwich street, New York city, for example, is constantly working among his old customers figuring with them the economies which can be realized by the installation of tungsten and other high-efficiency lamps with proper reflectors. Mr. Ross says he realized some time ago that the most prolific field for the contractor lay in the line of redesigning present installations and reducing current consumption, and he has made a special study of the results which may be obtained in this work.

J. Francis Southgate, of Worcester, Mass., is another contractor who has made a number of installations of Holophane arcs and gem lamps, and materially reduced his customers' current costs.

Walter Kidde, of the West Street Building, New York city, though primarily a mechanical engineer engaged principally in the construction of large manufacturing plants, has considered the matter of illumination of the greatest importance, and in the plant of the Brunswick-Balke-Collender Company, in Long Island City, and their New York city show rooms has produced some exceptionally fine results. The efficiency and tone of the show-room lighting has called forth much favorable comment and attained considerable publicity.

Contractors must look the situation fair in the face and realize that the rapid strides of the last few years in this field have affected them quite as much as the lighting company itself.

Electric lights in future will be installed, not as lights, but "for illumination," and it rests with the contractor in large measure to facilitate this progression.

The Chicago Sanitary District Hydroelectric Development.

The investigating committee of the Citizens' Association, of Chicago, Ill., appointed to study conditions surrounding the Chicago Sanitary District hydroelectric development, has reported that if the district is not hampered in the future in its efforts to sell electricity its net income should amount to at least $500,000 a year. This capacity should be reached in six months. Ultimately the capacity may be increased to 80,000 horse-power, with a net annual revenue of $1,500,000. Since January the Sanitary District has installed three generators capable of producing continuously 16,500 horse-power, and for peak service 20,600 horse-power. In six months the plant should be capable of producing continuously 27,500 horse-power. This will be increased to 30,000 horse-power within two years, when the flow is increased by widening the river.

National Electrical Contractors' Association.

Eighth Annual Convention, Chicago, Ill., July 15, 16 and 17.

THE eighth annual convention of the National Electrical Contractors' Association will be held at Chicago, Ill., July 15, 16 and 17. Headquarters will be at the Auditorium Hotel, the registration department and directors' room being located on the parlor floor, the banquet room on the sixth floor being used for the business sessions. The registration department will be opened at 6 P. M., July 14. All badges and tickets for entertainment will be issued from the registration department and no badges will be issued until payment by party registering of the fee for tickets. The programme insures a pleasant and profitable meeting, and indications point to a large attendance. The general programme of the convention is announced as follows:

JAMES R. STRONG,
President National Electrical Contractors' Association.

W. H. MORTON,
Secretary National Electrical Contractors' Association.

JOHN R. GALLOWAY,
Treasurer National Electrical Contractors' Association.

JULY 15.

Open session, 10 A. M.

Business session, 2 P. M.

Men's banquet, 7 P. M., in large banquet hall of the Auditorium Annex.

Ladies' banquet, 7 P. M., in small banquet hall of the Auditorium Annex.

JULY 16.

Open session, 10 A. M.

Business session, 2 P. M.

Business session, 7 P. M.

Ladies' theatre party, 7 P. M.

Rejuvenation of the Sons of Jove, time and place to be announced later.

JULY 17.

All-day outing at Michigan City, boat leaving Chicago at 9 A. M. and returning at 6 P. M.

Both the open and business sessions will be held in the Assembly Room, on the sixth floor of the Auditorium Hotel.

There are a great many matters of importance to come before the business sessions and all of the members are requested to convene promptly and remain through the entire meeting.

The open sessions will be interesting and instructive, addresses being made by the following well-known men:

G. M. SANBORN,
First Vice-President, National Electrical Contractors' Association.

WEDNESDAY, JULY 15.

Address of welcome, president of the Electrical Contractors' Association of Illinois.

Opening address, James R. Strong, president of the National Electrical Contractors' Association.

"The Electrical Contractor's Opportunities in the Illuminating Field," George Loring.

"The Relations Between the Underwriters and the Contractor," W. H. Merrill, Jr.

THURSDAY, JULY 16.

"Illuminating Engineering," J. R. Cravath.

"The Relations Between the Lighting Company and the Contractor," Alex Dow.

"The National Electrical Contractors' Association," Seth B. Witherbee.

The local committee has practically completed all arrangements, and the following have been placed in charge of the different features of the entertainments: Registration, badges and tickets, C. R. Kreider; banquets, Ernest Freeman; entertainment and vaudeville, Arthur Frantzen; outing boat, Henry Newgard; outing grounds, Warren Orne.

The officers of the National Electrical Contractors' Association are as follows:

President—James R. Strong, New York, N. Y.

First vice-president—G. M. Sanborn, Indianapolis, Ind.

Second vice-presidents — Charles R. Kreider, Chicago, Ill.; F. C. Werk, Cleveland, Ohio.

Treasurer—John R. Galloway, Washington, D. C.

Secretary—W. H. Morton, Utica, N. Y.

Sergeant-at-arms—J. C. Sterns, Buffalo, N. Y.

IMPROVED CONDITIONS IN THE ELECTRICAL INDUSTRY.

SATISFACTORY RETURNS FROM ALL PARTS OF THE COUNTRY—INDICATIONS OF A RETURN TO NORMAL CONDITIONS.

That there is a well-defined improvement coming about in the electrical manufacturing industry is attested by the increasing volume of orders and inquiries for new material. Last week we published an interview with Walter H. Whiteside, president of the Allis-Chalmers Company, in which he spoke very encouragingly concerning the revival of business and the renewed activity in all branches of the industry. Supplementing his statement of last week, Mr. Whiteside says: "There is a continuation of the progressive conditions stated in my interview of last week. At the present rate of improvement normal conditions will again be realized within a very short time."

For the year ended June 30, 1907, the Allis-Chalmers Company showed an operating deficit of $387,298. The earnings for the year ended June 30, 1908, will show a substantial profit available for dividends on the preferred stock. The strength of the stock and bonds of the company is attributed to the better showing, not only in earnings, but in new business as well.

The business of the General Electric Company continues to show steady improvement. Gross sales of new apparatus are running now at the rate of fully $40,000,000 per annum, as against a rate of $35,000,000 per annum in February and April. The total of new orders for the three months was $10,033,172. During March several large orders were received. During the last two months there has been a steady accumulation of orders, and in the last month the company has been able to show gross sales of $3,500,000.

It is stated that there is no truth in the report that directors of the National Carbon Company are contemplating an issue of five per cent bonds to be used in retiring the $4,500,000 preferred stock and placing the common on a seven per cent basis. As a matter of fact, an increase in the National Carbon common dividend rate is an assured development for the future. Directors will not make any move, however, until the situation is more settled. Since the beginning of the current fiscal year, on February 1, National Carbon earnings have been running at the rate of about $900,000 net per annum, which compares with $924,801 for the fiscal year ended January 31.

The business of the Westinghouse Electric and Manufacturing Company is showing a gradual improvement. Recently the company received $400,000 in new orders within the course of two or three days. The orders this month are expected to show a substantial increase over the preceding month.

The hearty co-operation of the readjustment committee with the various other committees and the work performed by the former committee in making the plan successful are subjects of favorable comment on the part of the creditors and Westinghouse interests.

That the requests of the readjustment committee will be met before September 1 there is little room for doubt. The recent advance in the notes and bonds of the company indicates as much.

The Crocker-Wheeler Company reports a large increase in inquiries for motors, generators and other electrical apparatus which it is receiving through its branch offices all over the country. The company feels confident that when the great volume of business indicated by all these inquiries is under way normal conditions will again prevail.

Westinghouse Electric and Manufacturing Company Readjustment.

The readjustment committee of the Westinghouse Electric and Manufacturing Company in its report gives subscriptions to the merchandise creditors' plan as follows: By merchandise creditors, $4,135,912; by company's employés, $596,650; by stockholders, $2,214,300; by security investment company, $1,325,000; by George Westinghouse, $1,500,000. Total, $9,770,862.

Of this amount the subscriptions payable in cash as distinguished from those payable from the surrender of claims aggregate $5,634,950.

Upon the strength of these figures the reorganization committee announces its willingness to co-operate and to accept until September 1 the merchandise creditors' plan upon condition that the full conditions of the merchandise creditors be met.

The committee further recommends and requests the bank creditors to agree to accept in exchange for their claims one-half of the par value thereof in convertible sinking fund bonds of the company at par and for the other one-half either five per cent notes of the company in three equal amounts maturing respectively in four, five and six years from that date to the extent of thirty per cent of the face value of their claims and for the balance of their claims assenting stock of the company at par or at the option of the creditor in respect of the one-half of the claim not covered by the convertible bonds, five per cent notes of the company maturing fifteen years from that date.

Ohio Electric Light Association.

The fourteenth annual convention of the Ohio Electric Light Association will be held at the Hotel Victory, Put-in-Bay Island, Lake Erie, Tuesday, Wednesday and Thursday, August 25, 26 and 27. The following topics will be presented in the form of papers at the meeting:

"Should Central Stations Do Wiring?"

"Why Municipal Ownership of Lighting Stations Has Not Been a Success."

"How Can We Best Increase Our Business?"

"Experience with Luminous Arc Lamps."

"Electric Signs and Other Special Uses of Electricity as an Adjunct to Profitable Station Work."

"Gas and Gasolene Competition, and Best Ways to Meet It."

"Illuminating Engineering."

"Best Ways and Means of Keeping Out and Getting Out Private Plants in Central Station Territory."

"The Gas Engine in Central Station Work."

"Gas-Producer Plants and Oil Engines and Their Results."

Report upon the experience of a large number of central station men on the tungsten lamp.

DeForest Wireless Telephone Tests.

Lee de Forest, the well-known wireless telegraph and wireless telephone inventor, returned to New York recently after a long trip abroad. Mr. de Forest installed wireless telephone apparatus on several naval vessels for the Italian Government. During his stay in Paris he was afforded an opportunity by the French authorities of using the long antenna on the Eiffel Tower. It is stated that messages and songs by wireless telephone were picked up by warships near Marseilles, 300 miles distant. Mr. de Forest says that he heard very plainly the messages sent out from Glace Bay, on this side of the Atlantic, by the Marconi company. He believes that the Eiffel Tower tests prove that it is feasible to send messages from New York to Paris if the new tower of the Metropolitan Life Building, which is now nearing completion in New York city, can be used.

New Hydraulic Plant of Brillanne, France.

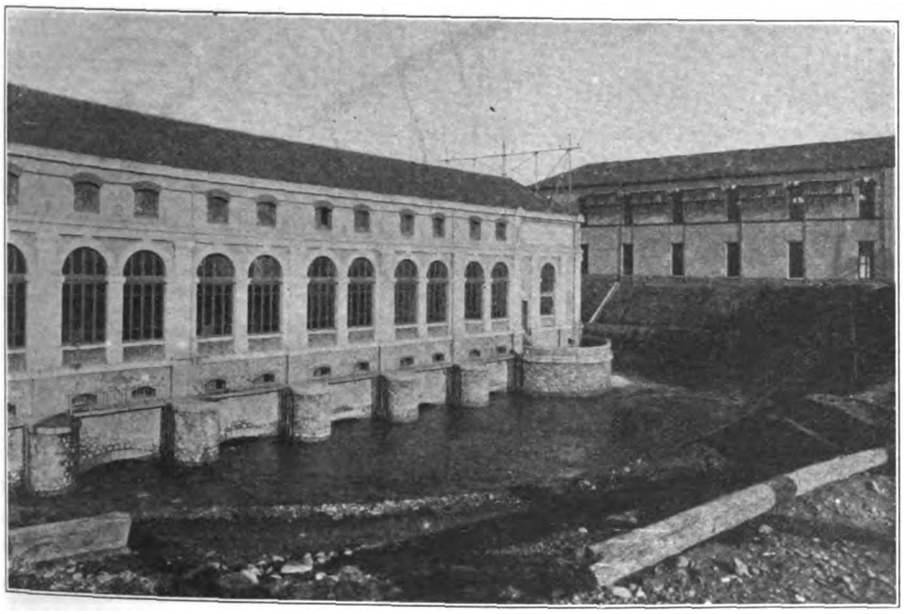
By C. L. Durand.

THERE has been recently opened in the Mediterranean region of France a hydroelectric plant which has a considerable interest from the fact that it is one of the largest to be erected in the south of France, and again, it uses the highest voltage, 52,000 volts, which has as yet been employed on the Continent.

The new plant is located on the Durance River, at Brillanne, and it forms part of the extensive system of hydraulic plants and pole-lines which are under the control of the Energie Electrique Company. Several of the already-existing power plants of this region have been described in previous issues of the ELECTRICAL REVIEW. Of late the enterprise has taken a considerable development, as it was desired to extend the system of pole-lines as far as the important centres of Marseilles and Arles. In Marseilles especially, a large amount of current is to be used, both for the lighting and motor circuits and also for the city tramways. In view of this fact the company has been engaged in constructing a number of new plants, of which the present station is the first to be finished.

Having a capacity of some 12,000 horse-power, the Brillanne plant is designed to work in connection with a second plant which is now being erected on the same river at Ventavon, about forty miles to the north, to furnish 15,000 horse-power. Following this there will be a number of other hydraulic plants finished in the near future in the same region. One of the largest of these is the Verdon plant, on the river of the same name, which is designed to give 15,000 horse-power. Other plants are the Timeé, Fontan and Sorge, etc.

Referring to the stations of Brillanne and Ventavon, located on the Durance River, these two hydraulic plants, the first of which has been in regular service for some months past, and the second in course of construction, are designed to be operated in parallel. At present they are connected together by two high-tension pole-lines. The total amount of power will be transported from the station of Brillanne by means of three high-voltage pole-lines on the one hand, which are constructed as far as Marseilles and are to end in a transformer station of large size. This latter station, which is one of the largest substations which has as yet been erected on the Continent, is located at the village of Allauch, a few miles' distance from Marseilles. An illustrated account of the Allauch plant has already appeared. Another part of the current from the hydraulic plant will be carried upon two high-tension lines which proceed in the direction of Arles and end at another substation which is to be erected in the neighborhood of that locality.



EXTERIOR VIEW OF THE BRILLANNE HYDROELECTRIC PLANT AND TRANSFORMER HOUSE.

The long distances which separate these hydraulic stations from the points of utilizing the current have resulted in the use of an unusually high voltage upon the pole-lines of the present system, the highest which has been reached as yet on the Continent. It is from 55,000 to 57,000 at the start of the pole-lines from the Ventavon plant, and 52,000 on the lines from the Brillanne station. The use of such a high voltage made it necessary to design a series of new machines and the accompanying apparatus for this tension. On account of the large amount of power which comes into play in the present case, there must be a distinct separation between the medium-tension machines and the high-tension transformers of the plant.

INTERIOR VIEW OF BRILLANNE HYDROELECTRIC PLANT.

A BANK OF THREE HIGH-TENSION TRANSFORMERS OF BRILLANNE HYDROELECTRIC PLANT.

The present account of the Brillanne hydraulic plant has been obtained from information on the subject which A. Garfield, one of the chief engineers of the

French Thomson-Houston Company, has kindly furnished the writer, and the illustrations will bring out the leading details of its construction. In general the plant is made up of two separate buildings, the first of which is designed to contain the main part of the running machinery, such as turbines and alternators, together with all their accessories for operation and regulation. The second building, which lies near the former, contains the main transformer room and here are installed the static transformers and the high-tension apparatus for regulating the lines at the point where they leave the station. The buildings are of a considerable size, and the turbine house covers an area of 1,000 square metres, while the transformer room covers 11,000 square metres.

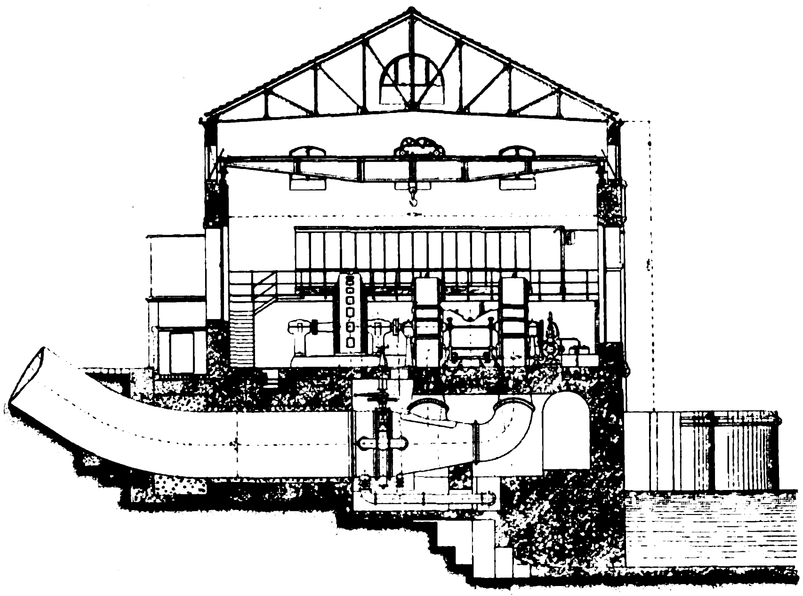
As to the hydraulic work which was carried out for the Brillanne station, it differs somewhat from the usual practice in the fact that there is no dam erected across the river at this point. The river bed is much too wide to allow of carrying this out in the present case. The water is accordingly taken off by a simple side canal, and as the current is rapid at this point, a sufficient amount of water is given by the canal for operating the station, the average flow being fifty cubic metres per second, and the minimum flow forty-five metres. The total length of the canal from the off-take point to the station is about eight kilometres, and the difference of level is thirty-eight metres. At a point midway in the canal it is enlarged considerably so as to form a vast settling basin, and here the width is forty-three metres. A dredge crane is arranged so as to take out the gravel which deposits here. Near the station the canal ends in a main basin built of masonry which has 8,000 square metres surface and is divided into two parts by a masonry wall. From here there are five penstocks of 2.7 metres inside diameter which lead to the turbine house, and a smaller one of 1.2 metres for the exciter turbines. After passing through the wheels, the water flows in an off-take canal of 1,030 metres length to the Durance River. This canal is taken across the railroad and the roads in two parallel flumes of fifty metres length.

The mechanical and electrical outfit of the plant, which was installed entirely by the present company, comprises five groups of turbine-alternators. The turbines are of the Francis pattern and are furnished by the Escher-Wyss firm, of Zurich, having two main wheels, each of which is mounted in a separate water-chamber. The two wheels have a common outlet for the water into the off-take canal. About 3,500 horse-power is the capacity of each of the present wheels, and they are designed for use upon a twenty-two-metre, net, head of water, including the height of aspiration, which varies between six and seven metres. A centrifugal governor of an improved type is provided for these machines, and it acts upon the crown containing the directing vanes by means of a relay motor. The latter is of the hydraulic type and works under oil pressure. The normal speed of the turbines is 250 revolutions per minute, but this speed can easily be raised or lowered so as to vary from 235 to 265 revolutions, either by simply working a hand-wheel or by the use of a small electric motor which can be operated from the main switchboard. This arrangement is indispensable for connecting the different machines in parallel in a rapid and efficient manner.

Each of the turbines is coupled directly and rigidly to the corresponding alternator. The latter machines have been designed specially for the present plant, and will produce three-phase current at twenty-five cycles, working at 7,500 volts normally. In this case the system of revolving field and fixed armature is used, and the field coils are formed of copper strip laid in slots in the laminated-iron field, while the armature winding is made up of lath-wound coils which are placed in the slots in the usual way. Each of the alternators has a capacity of 3,000 kilowatts.

For the exciting current of the five alternators of the plant there is provided a direct-current generator of 200 kilowatts, which delivers 110 to 125 volts to the exciter bars. There are two of these machines installed in the station, one of them acting as a standby. Both the generators are driven direct by Escher-Wyss turbines of the Francis type, of the 250-horse-power size. They are placed at one end of the dynamo room, along with a number of other groups which are used for various purposes throughout the station, including a set of motor-driven pumps for supplying the oil under pressure which is needed for operating the hydraulic motors of the governors.

Coming to the second part of the plant, the transformer post, this building is located at a hundred feet from the former. Here are installed the single-



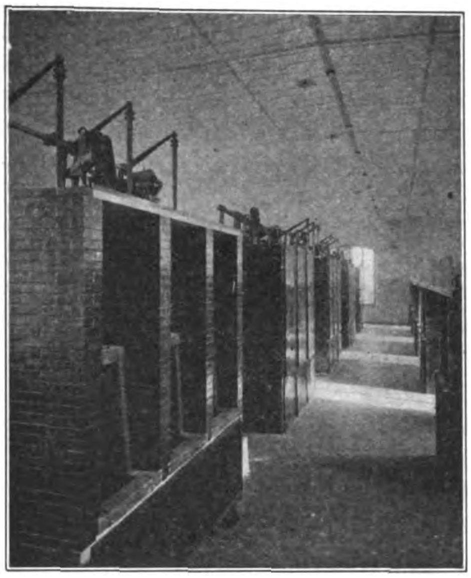
TRANSVERSE SECTION, BRILLANNE HYDROELECTRIC PLANT, SHOWING PENSTOCK AND DRAFT TUBES.

phase transformers of the plant, which are lodged in a series of cells or niches so as to be entirely enclosed when in normal service. These transformers are connected so as to deliver three-phase current, and as usual they receive the current from the alternators and are connected at the other side upon the pole-line. Each of the alternators of the plant has a three-phase, paper-insulated and lead-covered cable, which runs underground to the transformer room and is connected to a group of three of the transformers. The transformers are very well designed with respect to the high voltage employed. Each has a capacity of 900 kilowatts and a ratio of windings of 1 to 4, so that when they are connected in a set of three on the delta system on the low-tension side and on the star method on the high-tension side, they will raise the machine voltage of 7,200 to 52,000 volts between phases.

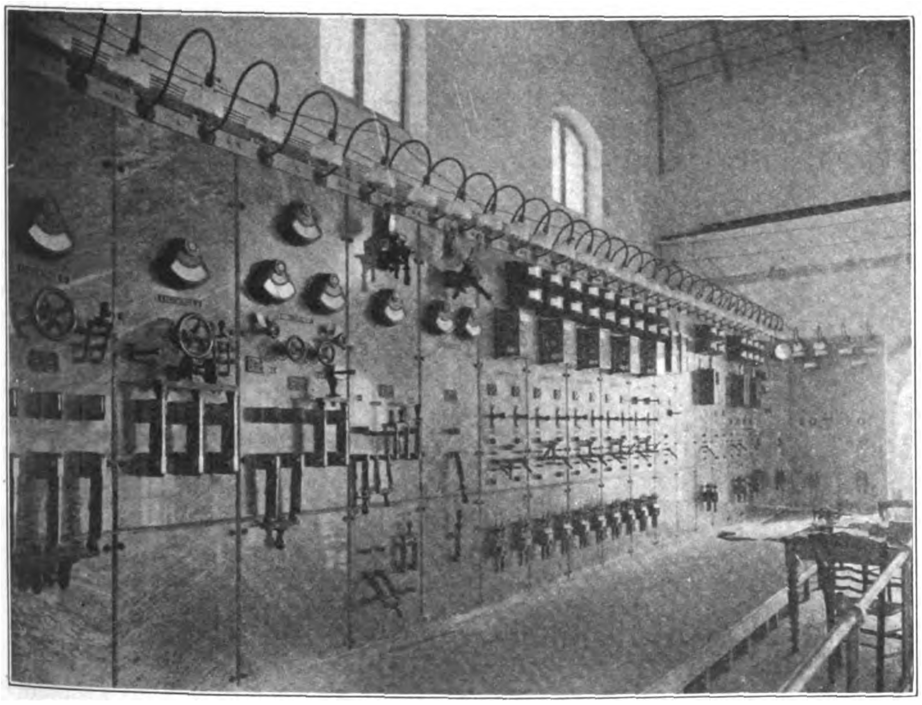
The present type of transformer required a very careful construction, and special attention was given to the insulation and to the cooling of the mass. The windings are entirely immersed in oil, and the latter is cooled in a constant manner by means of a cold-water circulation which takes place in a worm piping surrounding the body of the apparatus. A set of automatic signals has been provided for use with the transformers, and in case of an undue rise of temperature in any of the apparatus a corresponding signal is given to the attendants.

From each of the five groups of transformers corresponding to the alternators, current can be sent into the bus-bars of the switchboard. The bars are laid out in two series working at 50,000 volts, and the transformers can be switched on either set of bars. The latter are of bare copper wire of ten millimetres diameter. Each of the bars is mounted horizontally on triple-bell porcelain insulators of a special type, and is separated from the neighboring bar by a long slab of cement upon which are placed the insulators. Upon the bars are connected the starting wires for the three-phase pole-lines at 50,000 volts. The different circuits for the lines are also in bare copper. The method of mounting the transformers in the cells is seen in one of the illustrations. The overhead lines leave the station through a series of openings, and below these points is installed a series of lightning arresters of the Wunt pattern.

The different high-tension circuits (alternators, transformers and lines) are operated by special forms of high-tension switches of the company's design. These three-pole switches, whose phases are separated by brick partitions, have a double break in oil, and are operated each by a separate direct-current motor by means of suitable gearing and a set of jointed levers, which transform the rotary movement of the motor into a straight movement. This causes the operation of the switches by means of a set of rods, so as to open the three-phase high-voltage circuits. Strong springs give a quick break for the switches, preventing any arcing at the contacts. In this way it is easy to break a fully loaded line of 10,000 kilowatts working at 50,000 volts. The electric motor is started up by closing a small two-way switch which is mounted on the main switchboard and can be placed at any distance from the corresponding switch. Colored lamps on the switchboard are used to show at each instant the opening or closing position of the main switches in the other building. A set of automatic relays, which can be adjusted as desired, is used to open the main switches when the current rises too high. One of the illustrations shows the method of mounting the three-phase switches. Above will be seen part of the mechanism and the small electric motor. A set of iron covers closes the cells completely. Each set of three cells for a single switch is mounted separately, thus placing the switches a suitable distance apart. The constant value of the voltage is assured automatically at the ends of the pole-line at the substations of Arles and Allauch, that is, at a distance of about sixty miles from the hydraulic plant. This is carried out by an apparatus which is installed at Brillanne on the platform of the main switchboard. Switchboard transformers and a compensating apparatus are used in order to operate a low-tension circuit which serves as usual instead of a pilot wire. In the present case the apparatus is designed so that all the points concerning the line voltage and phases are reproduced in the indicator. The voltage of the low-tension circuit is used to operate the relay of the current-regulator, and its value corresponds at all times with that of the voltage at the distant ends of the line. The current regulator which is used in the present case is of the Thury pattern and is of double form; that is, it allows of a simultaneous and independent regulation of the voltage on each of the 50,000-volt bus-bars used for the start of the pole-lines. This takes place by the automatic working of a rheostat which is mounted in series on the exciting circuit of the alternator.



Automatic High-Tension Oil Switches in the Brillanne Hydroelectric Plant.



View of Main Switchboard and Distribution Panels, Brillanne Hydroelectric Plant.

The security of the personnel is carried out in a simple and effective manner. All the apparatus for the operation, regulation or measurement for the two buildings are, without exception, supplied at 110 to 125 volts. For the direct-current circuits this is done by the use of electric relay motors, and for the alternating-current by means of transformers of voltage and current which are connected upon the high-tension circuits for the measuring instruments. All the operations for the different machines and circuits, both direct and alternating, are carried out from the main switchboard, which carries all the needed indicators for working the station.

The Brillanne plant is now able to furnish regularly a total of 10,000 kilowatts, using a voltage of 50,000 volts between phases. At present there are four of the above-mentioned alternator groups in operation, and they have been delivering current in a regular way upon the line which passes to Marseilles at sixty miles distance. Current is used in the latter city for a number of mains, and this latter system, which is only in its first stages, will, no doubt, be increased rapidly in the near future. The first two groups and the pole-line have been working at 50,000 volts for some months past without any mishaps of any kind occurring upon the system during that time. At present the amount of power which is sent upon the line is estimated at 120,000 kilowatt-hours per day. A large part of the current is used in Marseilles by the gas and electric company of that city and also by the tramway company, which operates one of the largest systems on the Continent.

The overhead line is mounted in general upon iron trellis-work poles, which are made to take a comparatively straight course across the country and do not follow the roads. The poles are ten to twelve metres in height and are spaced seventy-five metres apart. On the poles are mounted three cables for the high-tension lines. One cable is placed at the top of the pole and the two others at the ends of a short cross-arm. Triple-bell porcelain insulators, tested at 120,000 volts, are employed.

BOOK REVIEW.

"Agenda de l'Electro." L'Electro. Brussels. Cloth. 280 pages. Illustrated. 4 by 6 inches. Price, 5 francs.

This is a useful little French handbook for engineers. It contains the usual information generally found in such works, such as the fundamental laws of electrical science, the principles of electrical applications, and practical information on electrical, steam and hydraulic machinery. Some interesting statistics of the electrical industries in Belgium are given and lists of technical societies and schools

Wireless Telegraph Companies Unite.

It is announced that the United Wireless Telegraph Company has obtained control of the International Telegraph Construction Company, one of its recent competitors. The International Telegraph Construction Company has built a number of stations in the United States and in several foreign countries. It is also stated that the United company has secured the services of Harry Shoemaker, the well-known wireless telegraph apparatus inventor.

FINANCIAL REPORTS OF ELECTRICAL COMPANIES.

KANSAS CITY RAILWAY AND LIGHT COMPANY.

The Kansas City (Mo.) Railway and Light Company's earnings for the year ended May 31, 1908, are officially reported as follows: Gross, $6,144,549; expenses and taxes, $3,684,457; net, $2,460,092; deductions, $1,380,254; surplus, $1,079,838.

ASSOCIATED BELL TELEPHONE OPERATING COMPANIES.

The report of all the associated Bell Telephone operating companies, not including the long-distance lines of the American Telephone and Telegraph Company, for the month of April and four months ended April 30, shows an April gross telephone revenue of $9,882,200; general operating and maintenance expense, $7,143,500; net, $2,738,000; sundry earnings, net, $399,800; total net, $3,138,500, an increase of $216,400 over the same period in 1907; interest, $641,800; balance for dividends, $2,496,700. From January 1 to April 30 telephone revenue amounted to $38,924,400; general operating and maintenance expense, $28,771,500; net, $10,152,900; sundry earnings, net, $1,636,000; total net earnings, $11,788,900, an increase of $1,142,600 over the same period in 1907; interest, $2,615,400; balance available for dividends, $9,173,500.

UNITED RAILWAYS OF ST. LOUIS.

The report of the United Railways Company, of St. Louis, Mo., for the month of May and five months ended May 31 shows May gross of $920,765; expenses, $591,543; May net, $329,222; charges, $232,278; May surplus, $96,944. Five months' gross, $4,248,216; expenses, $2,795,250; five months' net, $1,452,966; charges, $1,154,714; five months' surplus, $298,252.

MEXICAN AND CENTRAL & SOUTH AMERICAN TELEGRAPH COMPANIES.

A résumé of the operations since organization of the Mexican Telegraph Company and of the Central & South American Telegraph Company has been issued as a joint statement by James Scrymser, president of both companies. Many inquiries have been made concerning the value of these properties, as the shares of the company have been traded in very little on the Stock Exchange. During 1907 235 shares of the Mexican Telegraph Company changed hands at prices ranging between $235 and $250 per share. In 1907 5,945 shares of the Central & South American Telegraph Company were sold at prices ranging from $105 to $110 per share.

The first cable of the Mexican Telegraph Company was laid in 1881, the second in 1889, the third in 1905, all in the Gulf of Mexico. The 1881 cable has been occasionally interrupted by abrasion on reefs, but in every instance the cable, beyond the point of interruption, has been found to be in excellent condition. The 1889 and 1905 cables have not been interrupted and are in good electrical condition. The company owns 738 miles of the New York-Colon cable laid in 1907.

From March, 1881, to December 31, 1907, the receipts of the Mexican Telegraph Company were as follows: Gross, $10,782,182; expenses, $2,717,972; net profit, $8,064,210; dividends, $4,629,264; surplus, $3,434,946; invested in plant, $1,053,051; surplus, December 31, 1907, $2,381,895. There have been issued to shareholders as dividends full-paid shares amounting to $1,734,500. The operating expenses, repairs and renewals of the company for twenty-seven years have averaged about twenty-five per cent of the gross receipts. Dividends at the rate of ten per cent have been paid for the past twenty-one years.

The cables of the Central & South American Telegraph Company are 10,617 miles in extent. Three thousand three hundred and eighty-two miles were laid in 1882; 1,544 in 1891; 2,524 in 1893; 1,659 in 1906 and 1,508 miles in 1907. The receipts of the company from 1882 to December 31, 1907, were as follows: Gross, $21,247,405; expenses, $8,108,047; net, $13,139,358; dividends, $9,536,180; surplus, $3,603,178; invested in plant, $2,583,359; surplus December 31, 1907, $1,019,819. There have been issued to shareholders as dividends full-paid shares amounting to $2,732,800. Since 1897 dividends have been paid to shareholders at the rate of six per cent per annum.

The estimated report of the Central & South American Telegraph Company for the quarter ended June 30, 1908, gives gross of $408,000; expenses, $162,000; net $246,000; other income, $5,500; total income, $251,500; dividends, $143,565; surplus for quarter, $107,935; previous surplus, $1,172,712; total surplus, $1,280,647. The directors of the company have declared the regular quarterly dividend of one and one-half per cent, payable July 9 to stock of record June 30.

London Physical Society.

At the meeting of the London Physical Society, held at the Royal College of Science on May 8, Dr. C. Chree, president, in the chair, a paper on "A Modified Theory of Gravitation" was read by Dr. C. V. Burton. If we are to regard gravitational attraction as exerted through the medium of the ether, it appears to the author difficult to avoid the conclusion that the very great (or possibly infinite) velocity with which such attractions are propagated is due to the very great (or complete) incompressibility of the ether. This conception is embodied in the pulsatory theories of Hicks and of subsequent writers; the chief outstanding difficulty has lain in providing for that agreement of phase which must be assumed to subsist among the centres of pulsatory disturbance associated with the mutually attracting masses. This difficulty is avoided if we suppose that primary waves of compressional-rarefactional type are being propagated through the ether with a velocity enormously transcending that of light. These primary waves may be traveling in directions indifferently distributed, or predominantly or exclusively in one direction; but an essential point is that all effective wave-lengths should be very great, measured even by astronomical standards. Thus the pressure changes will be sensibly in the same phase over considerable regions, and if the ethereal compressibility is locally increased (or diminished) by the presence of electrically neutral matter, every particle of such matter will act as a centre of pulsatory motion.

For the electron, so far as concerns this modification of ethereal compressibility, a specification is assumed which involves no restraint on the free mobility of the electron through the ether. Incidentally the dynamics of the problem assumes a relatively simple form, and a value which could be quite insignificant attaches to a "gravitational (or non-electromagnetic) term" appearing in the expression for the total inertia of an electron. It has to be shown that, in its primary aspect, the assumed wave motion would give rise to no observable effects. This, in fact, follows from the assumptions made, and it is only through the feeble secondary effect of gravitation that any evidence of the wave motion could be obtained. In attempting to work out the theory on a numerical basis, values have to be found for a considerable number of physical quantities, several of these requiring to be independently conjectured, before the remaining quantities can be determined. But the range of the values which could be reasonably assumed is a good deal more restricted than might be supposed. The author gives a plausible set of values for these physical constants.

C. S. Whitehead asked if the amount of energy stored in the ether was greater or less than it was in the past.

Professor C. H. Lees asked if the ether considered was the old one or a new one. He referred to an interesting point in the author's representation of gravitation—namely, that matter was produced by the absence of something from the ether. In the theory advocated by Osborne Reynolds matter was produced by a deficiency in the normal piling, and recent theories seek to explain matter and gravitation by the absence of something which is present in free ether.

Dr. C. V. Burton, in reply to Mr. Whitehead, said he was not aware whether the amount of energy in the ether varied with time or not.

A paper on "An Examination of the Formulæ for the Grading of Cables" was read by Mr. C. S. Whitehead. In the *Journal* of the Institution of Electrical Engineers, of Great Britain, both M. O'Gorman and Dr. A. Russell have shown that it would be advantageous if cables for electric lighting were constructed so that the component of the electric intensity along a radius (in cylindrical co-ordinates) was kept constant for all points in the dielectric in the same plane perpendicular to the axis. They both find that to attain this object λr ought to be kept constant if the current is alternating, and σ/r constant if the current is steady, where λ is the specific inductive capacity, σ the specific resistance and r the distance from the axis. In this paper the question is regarded from a much more general point of view. Maxwell's two curl relations are taken in cylindrical co-ordinates, and it is supposed, as is quite legitimate, that the electrical and magnetic quantities are symmetrical round the axis, and that they vary as $e^{i(mz+pt)}$. We can then solve the equation, and from the continuity of the tangential components of the electric and magnetic forces obtain an equation to find m. If P is the component of the electric intensity along a radius, β the component of the magnetic force perpendicular to a radius in a plane perpendicular to the axis, we find

$$P = -\frac{im\,\beta}{\frac{4\pi}{\sigma} + \frac{\lambda\, ip}{c^2}},$$

where c is the ratio of the electrostatic to the electromagnetic unit of electrical quantity. Also if I be the total current in the wire parallel to the axis, and we neglect the displacement-current in the wire in comparison with I, we have $\beta = 2\,I/r$. Putting $m = -a + ib$, it is found that $\sqrt{a^2 + b^2} = \sqrt{\lambda}\,.\,h$, where h involves no quantities which have reference to the dielectric. Taking the real parts and putting P_0 and I_0 for the factors of P and I which are independent of the trigonometrical factor, we obtain

$$P_0 = 2\,I_0\,e^{-bz}\frac{c^2}{\lambda r}\sqrt{\frac{a^2+b^2}{p^2+\left(\frac{4\pi c^2}{\lambda\sigma}\right)^2}}.$$

If we suppose I_0, a, b to be constants of the cable which do not vary as we vary λ or σ, we get the rules given by O'Gorman and Dr. Russell. Thus let σ be very great, then to keep P_0 constant we must make λr constant, but if $p = 0$, that is for steady currents, we must make σ/r constant. We have seen, however, that $\sqrt{a^2 + b^2}$ varies as $\sqrt{\lambda}$, so that in case σ be very great this process suggests the rule make $r\sqrt{\lambda}$ constant. When $p = 0$ it is shown that $a = 0$ and that b varies inversely as $\sqrt{\sigma}$, so that this case suggests the rule make $\sqrt{\sigma/r}$ constant. The equation for P_0 is, however, strictly true.

Dr. A. Russell complimented the author on his interesting paper and on the skill with which he had handled the mathematical equations. The question of the grading of cables was one of great importance to the electrical engineer, and it was necessary to attack it both from the mathematical and the experimental side. The author took the case of an infinitely long concentric main and assumed that the amplitude of the current remained constant. In the practical problem the main is of finite length and the amplitude of the applied voltage is constant. The mathematical difficulties in the way of getting a complete solution were great, and so he hoped the author would continue his investigations further. Dr. Russell exhibited a portion of a Jona graded cable which had successfully withstood a testing pressure of 150-kilovolts applied between the core and the lead sheath. If the dielectric had been air a disruptive discharge would have ensued at twenty-three kilovolts.

The Colorado Electric Light, Power and Railway Association.

The next annual convention of the Colorado Electric Light, Power and Railway Association will be held at Glenwood Springs, Col., September 16, 17 and 18. J. F. Dostal, 405 Seventeenth street, Denver, Col., is secretary and treasurer of the association.

Electrical Notes from Great Britain.

(From Our British Correspondent.)

IN the ELECTRICAL REVIEW for January 4, 1908, the writer gave an account of the progress that had been made with the Transcontinental Telegraph system of Africa. The length of telegraph line remains unchanged, being still 1,584 miles, and the deficiency between the cost of working and revenue continues to be advanced to the telegraph company by the British South Africa Company. There is, however, now a prospect that wireless telegraphy is going to render an important extension of the system possible. The German authorities are considering a scheme for installing wireless telegraphy in German East Africa. The telegraph company's northern terminus is at Udjidji, on the east coast of Lake Tanganyika, and if the German scheme makes co-operation possible, the company proposes to erect two wireless stations connecting Udjidji with Gondokouro, the southernmost point of the Soudanese telegraph, some 700 miles away. This would complete the Cape to Cairo system.

The Irish power scheme, the outstanding feature of which was the proposal to utilize peat as fuel, and to which reference was made in these notes a couple of months ago, when a parliamentary committee threw out the bill, has been again receiving attention. After its rejection it was ordered, in the House of Commons, that the bill be recommitted to the committee, and in a very much altered form it has now been reconsidered. As it now stands it is a far less ambitious proposal. The city of Dublin and important urban districts are excluded from its provisions, the capital powers are reduced by two-thirds to only $750,000, and the new designation is the Central Ireland Electric Power Bill. The peat-fuel proposition stands unaltered. The committee has passed the preamble and the revised scheme looks like going through.

The annual statement of our Controller of Patents shows that 29,040 applications for patents were received during 1907, and 16,272 were granted, and paid fees amounting to, roughly, $1,326,000, as compared with 30,030 applications in 1907, with only 14,700 granted, producing in fees $1,279,000. As to the trend of invention, there were signs that the great activity of the last few years in motor-car lines is falling off. If titles are a true guide there is a falling off of thirty-five per cent in motor road-vehicle patents. It appears that the occurrence of several serious railway accidents, owing to the failure of signals, turned attention largely to automatic electrical systems of signaling in which the services of signalmen are entirely dispensed with and the signals are given on the engine itself. Several applications were made for stopping trains automatically when the signals are against them. Further, owing to a number of lift accidents, inventors have been busy improving devices for preventing mine or other lift cages from falling should the hoisting cable break. In wireless telegraphy and the telegraphic transmission of portraits and designs there was also noteworthy inventive activity.

For Manchester Corporation electricity works extensions there have just been ordered a 6,000-kilowatt Zoelly turbine with Siemens three-phase alternator and a Contraflo condensing plant. The turbine will be built at the works of James Howden & Company, of Glasgow. The largest turbine of this type at present at work in this country is one of 2,000 kilowatts at Powell-Duffryn Collieries, at Aberaman, in South Wales. The last-completed turbo-alternator at Manchester was described in the ELECTRICAL REVIEW several weeks ago.

The electric-sign business in England is a small affair at present, but it is a direction in which there has been decided advance during the last winter or two. The best thing yet announced is the decision of all the principal tube and underground railways of London to place outside their stations large electric signs with the word "Underground." Altogether there will be some 700 signs of Hawkes' manufacture, the cost being more than $60,000. Each station is to have the "Underground" sign down the outside of the building, and outside either stations or booking offices there will be maps engraved on glass showing the routes followed by the different electric lines.

Lord Vaux of Harrowden, addressing shareholders the other day, told them that the Brush Electrical Engineering Company had had a record output during the year, but, owing to low prices, the profits were not commensurate with the business done. He added, however, that manufacturers were now beginning to hold out for better prices, which would at least give a reasonable prospect of a living profit being earned. Lack of working capital, the stoppage of the demand for tramcars, the unremunerativeness of motor-bus building, and other like misfortunes, formed chapters in his lordship's tale of woe. Tramcar inquiries for two years past had been so small that the company had been compelled to cultivate foreign markets, though they preferred home orders if they could be obtained at fair prices. At the same meeting Lord Vaux resigned his chairmanship, and E. Garcke takes his place. It is stated that a scheme for the reconstruction of Bruce, Peebles & Company, now in liquidation as already reported, has been prepared and has received the approval of committees of creditors and shareholders.

Arthur Wright, of demand-indicator fame, has, in his capacity as consulting electrical engineer to the Marylebone Borough Council, reported on the question of revising the present charges for electrical energy and the practicability of framing a tariff which could be applied universally throughout the borough. His observations are of special interest as bearing upon the present position of affairs. He concludes that it is "commercially inexpedient" to raise the average price per unit or to interfere during the present year with the option which the old "Metropolitan" consumers have of remaining on their original scale of charges. The whole question of electric lighting revenue is in a very critical state owing to the rapid introduction of metallic-filament lamps, and he says that the only chance of obtaining a revenue sufficiently large to meet the expenses of the undertaking is to encourage in every possible way the increase of the lighting business. The revenue this year will not warrant the council in running too great risks of the loss of business which might follow the compulsory change of tariff to 4,000 consumers, that being the number of those at present on the old "Metropolitan" scale.

The president of the Municipal Electrical Association, H. Talbot, the city electrical engineer of Nottingham (in which place the four days' convention, concluded on July 3, was held), referred in his opening address to the continued apathy of assistant engineers, who do not take sufficient interest in the association to become associates or to compete for traveling studentships. There are more than 800 assistant engineers in the United Kingdom and only sixty-one have joined. This year no associate has contributed a paper and there is a decrease in their numbers. The reason is that they are unable to attend the conventions and they can read the papers in the press. Mr. Talbot thinks that it ought to be made possible for many of them to attend if they desired, seeing that the conventions are held in the summer when stations are working at their minimum output. Concerning metal-filament-lamp progress he says that any improvement in the "present extravagant methods of producing light must eventually prove beneficial to everyone." "For the time being it may go hard with contractors for electrical plants, as extensions will not be required so soon." Speaking of the city of Birmingham's announced intention to register wiring contractors who are authorized to carry out installations there, he said that registration would be a means of minimizing, though not preventing, bad and scamped work; it would tend to guard against "the deplorable ignorance of some of the electrical workmen of to-day." He advocated an entirely national scheme of registration carried out by the Electrical Contractors' or similar association. He suggested that it should be conditional on the gaining of a certificate for the passing of a fairly elementary examination on somewhat similar lines to that instituted by the Worshipful Company of Plumbers. Referring next to the subject of town's refuse as fuel for generating stations, Mr. Talbot said that incineration was an effectual and cheap way of getting rid of refuse, but "It is a certain fact, notwithstanding, that the handling and burning of the refuse alone costs more than the same output could be obtained for at the coal-fired generating station." The necessity for placing electrical undertakings in a sound financial position by establishing reserve and depreciation funds, the question of purchasing meters out of revenue, and the desirability of having uniformity of plant in a station, if it can be secured without sacrificing efficiency, were other matters briefly touched in the address.

The members then proceeded to consider a paper written from the councillor's point of view. The following day was given up to an excursion to Dovedale. Next day, July 2, and also July 3, the following papers received attention: "Considerations on the Design of a Generating Station," by H. Richardson, city electrical engineer, Dundee; "Reconstruction of an Electric Lighting Scheme with Observations on the Working of a Combined Steam and Water-Power Plant," by C. M. Shaw, chief electrical engineer at Worcester, where both types are at work; "'A.C.' Accumulator Substations, and the Use of Accumulators for Peak Loads," by A. M. Taylor, assistant electrical engineer at Birmingham; "The Work and Equipment of a Testing and Standardizing Department," by H. A. Ratcliff, of Manchester Electricity Works.

Toward the end of May an electric locomotive which was standing at Clapham Common Station of the City & South London Railway was found to be on fire, but it seemed at the time most unlikely that the cause was electrical. The matter was promptly investigated by A. P. Trotter, the electrical adviser to the Board of Trade, and his report is now issued. He says that there seems to be no evidence to show that the occurrence was due either directly or indirectly to the electric current, and that it is impossible to connect it with any electrical cause. He gives three possible causes, which are: (1) a lighted match thrown down by a man just before leaving; (2) the emergency oil lamp which may not have been extinguished; (3) spontaneous firing of oily waste in the cupboard. The fire seems to have burned most fiercely at the corner where the cupboard stands, and at the opposite corner where there was a considerable collection of insulated cables. The locomotive contents, including the controllers and other machinery above the floor level, were destroyed. The inside of the carriage next to the locomotive was uninjured, which circumstance leads Mr. Trotter to refer to it as a point in favor of separate locomotives.

The proceedings of the committee which is dealing with the London Electric Power bills continue to drag along. The case for the London District scheme has been most patiently heard. Perhaps the most important, or at any rate the most interesting, witness against the scheme was J. D. Falconer, a financial authority, who was, with Mr. Merz, practically the leader of the administrative schemes of 1905 and later, which failed. The chief point in his evidence was that showing why there had not been another Merz administrative scheme brought forward this year. He said that he and some others had come to the conclusion that while his 1905 scheme gave good promise of being profitable at that date, because of the backwardness of the existing authorities in catering for the power-user's requirements, the case was different to-day, for the companies had had several years in which to make up for their previous shortcomings. The case for the District bill was finished before the Whitsun vacation. On June 16, when the proceedings were resumed, the particulars of, and arguments for, the joint linking-up scheme of the eight existing companies were receiving consideration.

The report of the British Electric Traction Company, which has been awaited with some interest owing to the directors' announcement some months ago deferring the payment of preference dividend until the year's accounts were completed, has been published. The company has holdings to the tune of close upon $25,000,000 in electric tramway, lighting and power companies, of most of which it is the parent. On $10,000,000 of this (four and one-half per cent and five per cent debenture stock) interest is paid as usual. There next rank for dividend $8,100,000 six per cent cumulative preference shares —on these only three per cent can be paid this year; and all the ordinary shares, $6,600,000, again receive nothing, as was the case for 1906. The importance of making further provision for depreciation and of keeping ample funds in hand with which to "start upon new enterprises when opportunity offers" are the reasons for the position. Last year's bad weather was a hindrance to all tramway companies, and efforts to raise fares to more reasonable figures did not show effect early enough. Sixty of the British Electric Traction associated undertakings have federated for co-operative purposes under the British Electrical Federation. A building is now erecting in London where they will all have their head offices; they are purchasing stores collectively, have a mutual tramway insurance system, and in other ways secure co-operative economy. The report refers to the manifold difficulties placed in the way of conductors of electrical enterprises in Great Britain, and says that the directors are giving consideration to proposals for electrical enterprise submitted to them "from countries where the conditions for the investment of capital are more favorable than in this country."

London, June 27.

REVIEWS OF CURRENT ENGINEERING AND SCIENTIFIC LITERATURE

On First-Aid Work in Central Stations.

The author of this article, S. Lees, criticizes the arrangements ordinarily provided in manufacturing and engineering concerns for rendering first aid in cases of injury to limb or where an employé is suddenly taken ill. During many years' experience in central stations the writer has observed that almost utter indifference is paid to the most important question of ambulance equipment. In any works where there is running machinery accidents to employés are of frequent occurrence. Although these are mostly of a trifling nature if attended to at once, yet needless suffering is frequently caused by ignorance of unskilled persons and lack of proper appliances. It is not only in the matter of lack of provision of ordinary requirements for properly taking care of injured employés that central stations are at fault, but very often the safeguards are really added menaces to life and limb. It is the duty of managing authorities to see that a complete ambulance outfit is provided, and it is equally important that they insist on their workers being efficiently trained in first-aid work. Ambulance material should be carefully handled, and the materials employed should be kept isolated from any possible contamination. A first-aid box is described, together with the materials which should be secured for properly carrying out first aid.—*Abstracted from the Electrical Engineer (London), June* 19.

Distant Electric Vision.

In a communication A. A. Campbell-Swinton makes objection to Shelford Bidwell's communication on the subject of distant electric vision which was published in the issue of June 4. He points out that though, as stated by Mr. Bidwell, it is wildly impracticable to effect even 160,000 synchronous operations per second by ordinary mechanical means, this part of the problem of obtaining distant electric vision can probably be solved by the employment of two beams of cathode rays (one at the transmitting and one at the receiving station), synchronously deflected by the varying fields of two electromagnets placed at right angles to one another and energized by two alternating electric currents of widely different frequencies, so that the moving extremities of the two beams are caused to sweep synchronously over the whole of the required surfaces within the one-tenth of the second necessary to take advantage of visual persistence. So far as the receiving apparatus is concerned, the moving cathode beam has only to be arranged to impinge on a sufficiently sensitive fluorescent screen and give suitable variations in its intensity to obtain the desired result. The real difficulties lie in devising an efficient transmitter, which, under the influence of light and shade, shall sufficiently vary the transmitted electric current so as to produce the necessary alterations in the intensity of the cathode beam of the receiver. Possibly no photoelectric phenomenon at present known will provide what is required in this respect.—*Abstracted from Nature (London), June* 18.

The Kearney High-Speed Railway.

On June 13 a public demonstration was made of the model high-speed railway designed by E. W. C. Kearney, at Aldwych, England. This is a system in which the cars are run on a monorail laid on the ground, and are steadied by wheels running under an overhead rail. The centre of gravity of the car is kept low by the motors, and the pressure on the top guide rail is therefore not very considerable. On curves the position of this rail is altered to suit the speed at which the train is intended to travel, and is more strongly supported. The inventor claims that derailment is impossible. It is in tube railways that he hopes first to apply the principle. In such cases a rigid support for the top guide rails is provided by the roof. It is also proposed to do away with the necessity of elevators by bringing the trains to a platform just below the street level, from whence the train will run down a gradient of one in seven, so that within twenty seconds of leaving the platform a speed of fifty miles an hour will have been reached. During this time it is stated that passengers will be unconscious of sitting on an inclined plane, owing to the forces due to acceleration exactly counterbalancing the effect of the gradient. For bringing the train to rest it is to ascend a similar gradient of one in seven to each station, so that braking is apparently done away with. Mr. Kearney claims that the cost of tubes built on his system will not exceed £250,000 per mile, as compared with £500,000 per mile for ordinary tubes. A scheme has also been sketched for applying the system to elevated street railways. The scheme meets with little encouragement, and it is not expected that much will develop as the result of these experiments and tests.—*Abstracted from the Electrician (London), June* 19.

The Electric Lighting of the Rotherhithe Tunnel.

On Friday, June 12, the Rotherhithe tunnel was formally opened by the Prince and Princess of Wales. The new tunnel, undertaken in 1904 by the London County Council, links up the districts on the north and south of the Thames between the Tower bridge and the Blackwall tunnel. The work was carried out to the designs and under the supervision of Maurice Fitzmaurice, chief engineer to the London County Council. The tunnel under the river is 1,571 feet long, and the approach tunnels, cut-and-cover work, and open approaches, make a total length from entrance to entrance of 1.3 miles. The tunnel is thirty feet in diameter outside the lining, the gradients at the end portions being one in 36.5. The central under-river length has a grade of one in 800. Four shafts, sixty feet in diameter, are provided, two on each side of the river, and in two of them are spiral staircases leading to the surface. The electric lighting is on a generous scale. Three rows of metallic-filament lamps run all through the covered portion of the works, the lamps being of thirty candle-power placed thirty feet apart. The candle-power provided works out at one-eighth candle per square foot. There are altogether 631 thirty-candle-power lamps and 108 fifty-candle-power lamps, the latter being used mostly in the approaches, domed shafts, etc. The London Electricity Supply Company and the Bermondsey Corporation furnish the supply. The former is alternating current at 110 volts, and is used for lighting, and the latter is direct current at 480 volts, and is used for the pumping machinery. Both supplies are made available for both purposes by the use of motor-generators. In the event of failure of the lighting supply two thirty-kilowatt motor-generators are automatically started up on the direct-current supply, and within twenty seconds of failure the lamps will be lighted by the current generated by using the Bermondsey supply. In a similar manner, the failure of the supply for the pumps is guarded against, a twelve-kilowatt set being provided in this case, working with current from the London Electricity Supply Company and generating current for the pump motors. For handling storm water flowing down the approaches and the drainage from the washing down of the roadway, three electrically driven pumps are installed, each of 200 gallons per minute capacity against a head of seventy feet. One of these pumps is held in reserve.—*Abstracted from Engineering (London), June 19.*

The Centre of Gravity of Steam and Electric Locomotives.

W. H. Booth, the author of this article, holds that in their studies of electric locomotives electrical engineers have paid too little attention to what has already been accomplished or thought out in the past or forced upon the notice of engineers by the immutable laws of mechanics. In actual practice, the centre of gravity being about sixty inches above the rail, the angle of pressure of the resultant of any swaying movement of the centre of gravity is almost exactly sixty degrees. The tendency to force outward the rails is much reduced as compared with the tendency of the low-centre-of-gravity engine to do so. It has been argued that with a high centre of gravity an engine tends more easily to overturn, but while this may be the case it should not be forgotten that in rounding a curve the lateral tendency of the centre of gravity is to press the outer wheel more firmly down upon the rail, whereby its flange is restrained from mounting the rail. Were it not for this increased pressure the wheel would more easily mount the rail and run off. When an excessive speed is run around a curve either the engine will run off the rail or it will turn over. To check one tendency is to increase the other. Designers would do well to abandon the low centre of gravity. Much help would be given by raising the whole of the motor. Direct-connection, it is true, is much valued, but it may well be wondered if too big a price has not been paid for the abolition of the gears. This price has been the use of very small wheels, the necessity for very large motors, and the fixing of the centre of gravity very low, a lowness that has been accentuated by the absence of the boiler. In the steam locomotive all the moving parts and the cylinders and valves are practically at the level of the axle centre, and only the boiler remains to produce even a height of five feet. A first-class geared electric locomotive constructed in a steam-locomotive shop would prove that the geared electric locomotive is not, after all, of necessity a poor contrivance. It would enable radical differences of design to be introduced and put a stop to the necessity which at present seems to be paramount of the small wheel. Even with the best of design, assuming that the geared system proves all that can be desired or anticipated, it is not likely that the centre of gravity of the whole machine can be raised as high as it is in the steam engine, unless special highly placed weights are added for the purpose, and this is undesirable, as, indeed is all redundant weight. The weight of the motor parts should not come upon the wheels except through the intermediary of springs. This complicates the problem of gearing, but a solution seems possible in the direction in which it has been solved by the makers of traction engines, wherein a form of Oldham's coupling seems to give satisfaction in solving the difficulty of the gear centres.—*Abstracted from the Tramway and Railway World (London), June 4.*

The Electrical Installation at the New Public Offices, Whitehall, England.

The new block of public offices at the southern end of Whitehall, England, which will be the home of the local government board and the board of education, and later of the board of trade, has been practically completed. The lighting installation includes over 6,000 lamps. The building is supplied jointly by the Westminster and the London Electricity Supply corporations. The former supplies current for power and lighting and the latter for lighting only. The installation scheme provides for two pairs of service cables from each company's mains at different parts of the building, and there will be four separate main switchboards at these intake points. The Westminster supply is three-wire, direct current, 400 volts across the outers, and each main switchboard is divided into two halves, the 200-volt lighting circuits being balanced on each side of the three-wire system. The London company's supply is alternating. Two feeders supply two sets, each of three forty-kilowatt, single-phase transformers in parallel, these sets being in different parts of the building. These transformers step down the voltage from 2,500 to the lighting pressure of 200. Transformers are in a fireproof chamber adjoining the room containing the main switchboard. The handle of the high-tension, oil-break switch projects through a slit in the wall, so that the transformers can be isolated from the high-tension mains or changed over from one pair of cables to the other without entering the transformer chamber. The transformer chamber and main switchboards are situated in the basement proper, and from the four main boards 1,000-ampere flexible rubber cables lead down through openings in the floor of the subbasement. The cables are lead-covered, paper-insulated, and the joints between these and the short lengths of rubber cable are enclosed in specially designed ceiling boxes, one for each cable. From the 1,000-ampere cables 250-ampere cables run up to the submain boards in the basement. The iron troughing widens out where the cables enter the junction boxes, to the sides of which the troughing is bolted. There are about a dozen of these submain boards, each containing a double-pole switch and eight double-pole porcelain enclosed fuses. The boards are set into the eighteen-inch wall, and the backs of the boards are accessible from the other side of the wall. From this point the wiring is entirely in three-quarter-inch galvanized-steel seamless conduit. The fittings in the corridors and rooms are all hung on gimbals from the ceiling. Ceiling rose blocks are arranged in the centre of the rooms, so that a single electrolier or five separate flexible leads can be brought through ceiling eyes to separate counterweight lamps. All rooms are well provided with wall plug sockets, which are flush with the wainscoting and are not screwed onto the wood blocks sunk in the wall, but are sprung into brass rings attached to the blocks. Four handsome standards supported on marble pillars illuminate the grand staircase. The lamps are all 200-volt carbon-filament lamps, mostly of sixteen candle-power, a few eight-candle-power lamps being used in the corridors. Four thousand of the lamps are counterweight lamps, and there are over 1,000 wall plugs for table lights, etc. For the telephone service there will be two exchange rooms, and night telephones in several rooms on each floor will admit of direct communication to the hall porter. The elevators for the lifting of paper are electrically driven with push-button control. These can hoist one hundredweight at the rate of 120 feet per minute.—*Abstracted from Electrical Engineering (London), June 18.*

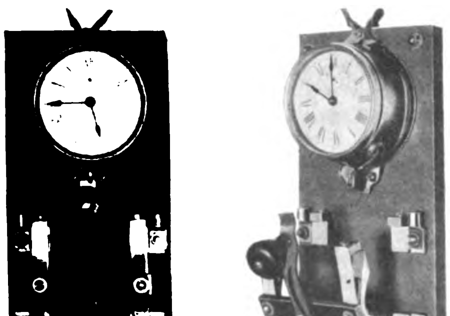
INDUSTRIAL SECTION

ILLUSTRATED DESCRIPTIONS OF NEW AND STANDARD ELECTRICAL AND MECHANICAL APPARATUS

IN THE following pages there will be found descriptions and illustrations of a large variety of apparatus which enters very extensively into the work of the electrical contractor. There has been a good deal of inquiry concerning the attitude of manufacturers with regard to the introduction of new appliances and the improvement of appliances for years well known in the electrical field. A great many of these devices are shown for the first time. It may be well, in passing, to state that no such eagerness to come strongly before the contracting fraternity as is evident at this time has been indicated for several years. Subsequent issues will contain further descriptions of apparatus used in this field.

The "Security" Automatic Time Switch.

In connection with the prevailing idea of increasing the hours of store lighting, contractors have frequently, within the last few years, been called upon to supply some means of arranging for the switching



"Security" Automatic Time Switch with Cover Removed.

off of the lights in a store window or, in fact, in the store equipment proper, at a predetermined time. In many of the larger cities this is accomplished by patrolmen, and it is part of the central station's work to see to it that the lights are not burned longer than the hour for which the contract is executed. In isolated cases, where the services of a watchman are not available, or where this periodic attention would cost too much, the automatic time switch fills the bill very nicely. In many cases, however, where the time switch is of elaborate construction, employing a multiplicity of contacts and an expensive clock movement, even the cost of this equipment makes it prohibitive. Where a cheap, simple, reliable and durable time switch can be secured, there is a considerable margin of profit for the contractor in handling and installing such a device.

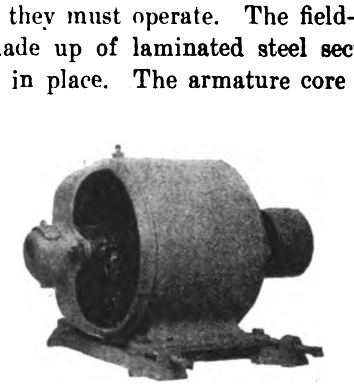
The F. Bissell Company, 226 Huron

"Security" Automatic Time Switch with Cover.

street, Toledo, Ohio, has placed on the market the "Security" automatic time switch, illustrations of which are shown herewith. This is an automatic circuit-breaker switch with an auxiliary carbon break. It operates by gravity and has no spring construction. It is impossible for the blades to stick. The back is flush, and all mechanism is on the face in plain sight. The switch is furnished for either on or off use, or for a combination of both.

Western Electric Company Direct-Current and Alternating-Current Motors.

Of particular interest to contractors are the direct-current motors of the "E" and "I" design, and the alternating-current motors of the "CP" design, manufactured by the Western Electric Company, Chicago, Ill. The "E" design comprises a line of motors ranging in size from one and one-quarter to seventy-five horsepower. These motors are furnished either open, closed with grids, or completely encased, depending on the conditions under which they must operate. The field-poles are made up of laminated steel securely bolted in place. The armature core is of



Two Horse-Power Motor, "I" Design.

a special grade of steel laminations which are carefully annealed after punching and treated with a coat of japan, insuring the lowest possible core loss.

The machines are furnished for either horizontal or vertical operation, and the bearing brackets of the horizontal machines may be shifted so that the motors can be suspended from the ceiling or walls wherever this is desirable. Especial care has been taken in the design of the brush rigging so as to insure the best brush contact and adjustment. The bearings are made especially large and strong, insuring cool operation and economical wear.

The line of small direct-current motors

Open Type Motor, "E" Design.

of the "I" design range in size from one-half to two horse-power. In the design of these motors special attention has been given to produce a motor that will be absolutely reliable in operating under the adverse conditions to which small motors are commonly subjected.

The frame and field-poles are made of a single casting of high permeability. By this construction all air-gaps, except those between the armature core and pole-faces, have been eliminated. The commutating field is made especially stiff, insuring sparkless operation for wide variations of load and speed. The bipolar type is used to prevent flashing under sudden and wide variations of load to which these motors

INDUCTION MOTOR, "CP" DESIGN.

are commonly subjected. The field coils are placed in an inclined position, so that the air currents set up by the rotation of the armature are met at all points by surfaces inclined to the direction of their motion. This feature accelerates the circulation and aids in the rapid distribution of heat generated under overloads.

The alternating-current motors are furnished either with squirrel-cage or phase-wound rotors, depending on the nature of the work they are to perform. The stator frames are of cast iron in one piece, and the section is such as to obtain the most rigid support for the laminations. The feet are broad, and the entire frame is so constructed that there can be no springing or vibration. Exceptionally high efficiencies and power-factors have been obtained for these motors by a special form of winding, liberal design, and by using the best grade of material throughout. All bearings are self-aligning and of the oil-ring type, and are housed in brackets of ample size to withstand the maximum capacities of the machines.

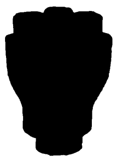
Some G & W Electrical Specialties.

The G & W Electric Specialty Company, 128 West Jackson Boulevard, Chicago, Ill., is calling attention to a number of time-saving, money-saving and trouble-saving specialties for central stations. Several of these specialties are illustrated herewith.

The type "MO" porcelain pothead is made up with single conductor tubes mounted in an iron case and with caps having one-inch holes. The lower casting is slipped over the cable and the lid and caps over the conductors. The conductors of the cable are separated, the joint is made, and the lower casting brought up in place, filled with compound to one and one-half inches from the top, and the lid set in place with the separated conductors passing through the tubes. The bottoms of the tubes are closed around the conductor by tape, and the tubes filled with compound to within one-half inch from the top. The caps are then drawn down into place and the conductors well taped down on the cap and several inches along the conductor. A few inches of braid on the wire is removed where it enters the cap, so that it will not act as a wick to lead water into the pothead.

The type "TS" porcelain pothead is a single-conductor, detachable pothead for high-tension and high-current duty. There are three porcelain members. The intermediate member provides a means of turning a threaded taper collar which

TYPE "MO" PORCELAIN POTHEAD



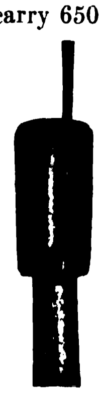
MULTIPLE-CONDUCTOR STATION TYPE POTHEAD.

TYPE "TS" PORCELAIN POTHEAD.

TYPE "S" PORCELAIN POTHEAD FOR HIGH VOLTAGE.

draws the two metal members together through the medium of the taper-headed plug and an externally threaded socket, thus insuring a tight-fitting joint. The standard size is designed to carry 650 amperes. This type of head is recommended when the disconnecting feature is required for loads above 150 amperes.

This type of pothead is well adapted to street railway work, as it will carry heavy currents, can be mounted on a pole without any protection from the weather, and can be disconnected under load by using ordinary precaution.



G & W GROUND-PIPE CAP.

The multiple-conductor stationary type of pothead has been developed to meet the demands for a station bell which is easy to install, low in first cost, and reliable. This head consists of a porcelain bowl and cover. The bowl is approximately seven inches in diameter at the top and four inches at the bottom. The bottom of the bowl is fitted with a metal plate provided with a collar drilled and tapped to size to screw upon the cable. The lid fits into the top of the bowl and is provided with the required number of holes and short tubes through which to pass the conductors. Owing to the manner in which the inside top edge of the bowl is cut away, the lid can be sealed into the bowl, thus excluding dust and moisture from inside the bell.

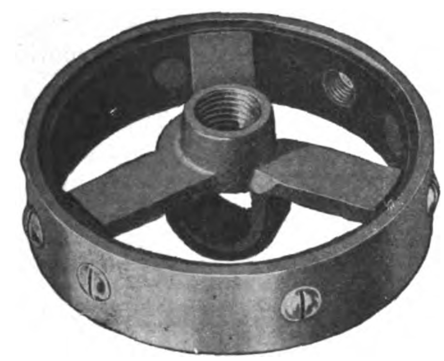
The G & W ground-pipe cap consists of a hollow galvanized malleable casting internally grooved along one side and so shaped at the mouth that the end of the ground wire can be introduced into the casting along the groove. The cap, with the wire in place, is put upon the top of the pipe and the pipe driven. In driving the pipe the cap is driven on and the copper wire wedged in securely between the inside wall of the cap and the outside of the pipe. The cap protects the top of the pipe from being battered out of shape, and saves the time required to cut off the battered end, as is often necessary in driving pipe in hard soils, and makes a joint of good conductivity between the ground wire and the pipe.

Oneida Galvanized Chain for Arc-Lamp Suspension.

One of the most important products turned out by the hardware department of the Oneida Community, Limited, Oneida, N. Y., is the Oneida galvanized chain. This is made in two sizes: No. 1, for suspending arc lamps, and No. 5, for suspending incandescent lamps. These chains can be used for any standard mast-arm. The chain is heavily galvanized and rust-proof. The fact that ice or sleet does not interfere with its ease of operation has been strikingly demonstrated at Niagara Falls, where a certain lamp was close to the cataract and the chain subjected not only to all conditions of weather, but to a continuous deposit of mist arising from the falls. The Buffalo & Niagara Falls Electric Company reported that the chains on this system worked perfectly throughout the entire winter in spite of the severe conditions.

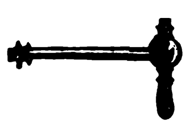
The Wakefield Standard Universal Lighting Fixtures.

The F. W. Wakefield Brass Company, Vermilion, Ohio, has placed on the market one of the greatest boons to electrical contractors in the Wakefield standard universal lighting fixtures. Recent developments in the art of electric lighting have made necessary the design of special fixtures, requiring large investments in order to carry a necessarily extensive line of designs. The adaptability of the Wakefield universal fixtures eliminates the necessity of carrying a large number of assembled fixtures, as it is possible by proper selection of stems and arms to adapt the Wakefield "body" to fit any requirement.



WAKEFIELD PATENT BODY.

WAKEFIELD CURVED ARM.



WAKEFIELD STRAIGHT ARM.

CLUSTER MADE WITH WAKEFIELD ADJUSTABLE FIXTURES.

Not only is it true that Wakefield fixtures are peculiarly adaptable to nearly all of the special needs of the trade, but it is also true that the principles of construction that are followed in building up these fixtures are such as will save the dealer and contractor much time and labor in assembling and installation.

As may be seen from the accompanying illustrations, the solid body contains no nipples whatever, and there are no inner iron bodies. A special feature which characterizes the arms and stems is that they all have a steel fish wire drawn through them, which allows the fitter to wire the arm in a very short time.

Hexagon arm backs on each arm permit the use of a wrench, removing the possibility of unsightly marks which are often left on the arms by the use of pipe pliers.

The body can be used for either two, three or four-light arm fixtures with a special provision that a light may be added to the bottom of any one of the fixtures. This feature, with the universal arms manufactured by the company, permits any style of arm on any style of stem with the various styles of plain, scroll and straight arms.

For each body either short or long stems are made for the construction of ceiling lights.

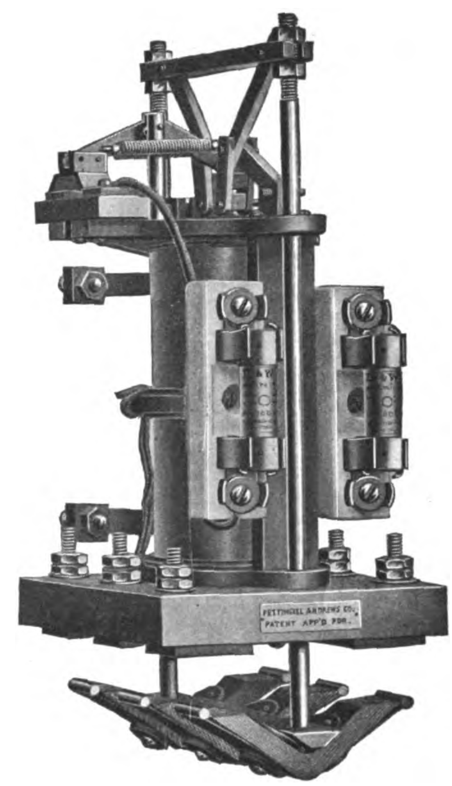
The arms and stems are made of heavy gauge stock finished in rich gilt, brushed brass or oxidized copper.

The cluster canopies are particularly important in making up special designs. These canopies are constructed of a heavy plain shell which is reinforced on the inner side by a casting, being fastened to the inner surface of the shell. The shell and castings are then drilled and tapped for either a one, two, three, four or five-light fixture. These outlets are fitted with small brass plugs which, when the shell is finished up, are left in the holes. The accompanying illustrations show a few of the many forms in which these fixtures may be assembled.

The Pettingell-Andrews Type D-2 Remote-Control Switch.

The Pettingell-Andrews type D-2 remote-control switch for either direct or alternating current has been designed along the lines of modern circuit-breaker construction, with laminated copper brushes and locking parts that are not called upon to carry current, and the entire mechanism is built up on a one-piece iron frame, so that neither rough handling in shipment nor constant pounding of operation will cause the fixed and moving parts to get out of alignment. The meritorious features of this device are well shown in the accompanying illustration.

The design of this switch precludes the possibility of the mechanism not completing its intended movement, either through a fall in the potential of the actuating circuit or due to too short a duration of the opening impulse or a careless manipulation of the control button. The switch is so assembled that it will fall open by gravity unless it is locked closed. There is no half-way point for it to hang. It is either locked closed by a steel-jointed toggle, hanging wide open, or traveling very fast toward one or the other of these positions.



PETTINGELL-ANDREWS TYPE D-2 REMOTE-CONTROL SWITCH, OPEN.

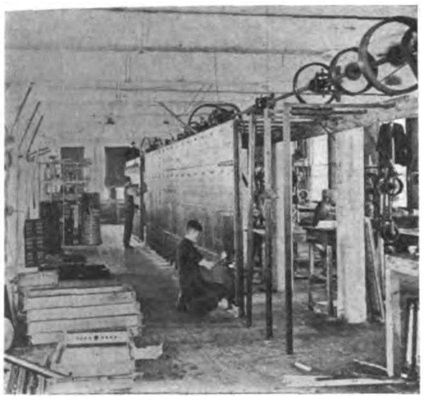
Some years of experience with arc-lamp cutouts enter into the design of the auxiliary break, and the operating current is broken with absolute certainty as the switch completes its closing movement.

These switches are made in the following capacities: Type D-2 are made with two, three or four poles up to 2,500 amperes, 250 volt, air-break, and 250 amperes, 2,500 volt, oil-break. Type D-3 and type D-4 are made for twenty-five amperes, 250 volts only.

This switch is made by the Pettingell-Andrews Company, Boston, Mass.

The Trumbull Electric Manufacturing Company.

Upon several occasions, so rapid has been the growth of the Trumbull Electric Manufacturing Company, of Plainville, Ct., as a switch specialist, it has been our pleasure to illustrate and describe in these columns the development of the company



Switchboard Department of the Trumbull Electric Manufacturing Company.

by text and with illustrations. At the present time this exploitation will suffice as far as the company's progress in the knife-switch field is concerned. There is another department, however, which is not so well known because it is of more recent development, namely, the panel-board and switchboard department. During the last year the growth of this department has equaled or even surpassed the record made

Slate Storage Department of the Trumbull Electric Manufacturing Company.

in the development of knife switches. Last summer, when the company's new factory was erected, it was intended to turn over about one-half of the four-story building, with about 22,000 square feet of floor space, to the panel-board and switchboard department. During the year, in spite of the market depression, this department has grown to such an extent that within a short time practically the entire building will be necessary for panel and switchboard work.

Familiar as the field is with the company's line of panel-boards, it is doubtful whether the great majority is acquainted with the extent to which these boards are used. A year ago the company's panels were ordered by the dozen; to-day they are sent out by the hundred, and cover every imaginable specification.

Last fall the department was entirely reorganized, and electrical engineers and assistants and other employés were recruited from the factories of some of the largest switchboard builders in the country, and a large number of successful bids were made for both government work and isolated plants.

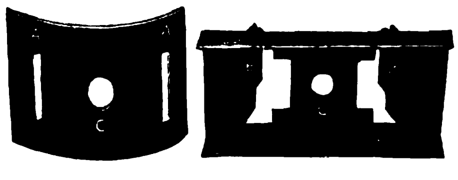
In entering this field the company realized the necessity of a thorough equipment to cover the most difficult specifications, and thousands of dollars have been spent in preparing to meet these requirements.

The company will shortly publish a list covering standard direct-current and alternating-current switchboard panels. There will be five distinct lines, covering specifications with and without circuit-breakers, with and without motors, and including complete economic arrangements for both central stations and isolated plants. With the line which the company will develop it will be possible for engineers to effect combinations to cover any kind of general requirements found in engineering practice. These boards will be kept in stock and can be shipped immediately.

Three Important Line-Construction Specialties.

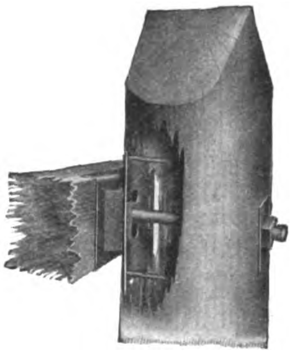
The Belden Manufacturing Company, 194 Michigan street, Chicago, Ill., has for a long time been favorably known as the manufacturer of a line of magnet wire and telephone cords. Recently the company has commenced the manufacture of several new patented devices for line construction work.

The Belden steel gain is a comparatively new device, although the construction departments of electric light, telephone, telegraph and power-transmission companies have seen the need of such a device for some time. The Belden wire test clamp or test connector has many advantages over the older forms of test clamps. The third device is known as the Belden ground clamp. This clamp possesses three features which particularly appeal to the user, namely, maximum strength, minimum price and great adaptability. One size fits all sizes of pipes. The steel gain is a steel support for the cross-arm which saves cutting gains in the pole and obviates the necessity of cross-arm braces except on longer than six-pin cross-arms. Referring to the illustrations herewith,



Component Parts of Belden Steel Gain.

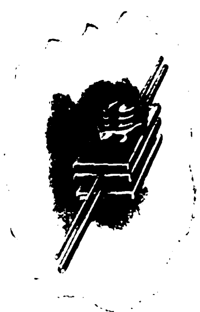
two tongues, B B, are cut from the back of the steel gain and these tongues inserted in the slots, A A. These are forced into the pole when the bolt is set up. The bolt passes through the cross-arm, the steel gain, and the holes, C C, and through the pole. This squares the cross-arm with the pole, fastening it securely in place. For power-transmission



Belden Steel Gain.

construction work extra heavy steel gains are made.

The use of the Belden wire test clamp is easily seen from the accompanying illustration. Essentially the device consists

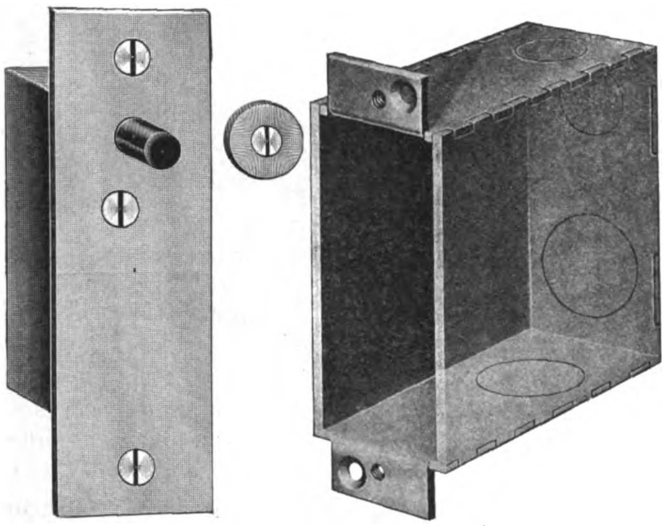


Belden Test Connector.

of a flat plate fitted with a slotted brass screw. The wire is placed in the slot in the brass screw and held in place by copper plate or leaves, one wire being placed between each pair of leaves and secured by a nut. The slot in the brass screw is large enough to receive any ordinary telephone or telegraph wire.

The "H. & H." Automatic Door Switch.

The accompanying illustrations show the automatic door switch and contain-



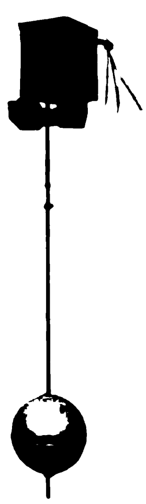
H. & H. Automatic Door Switch and Receptacle.

ing receptacle which has been placed on the market by the Hart & Hegeman Manufacturing Company, Hartford, Ct. This door switch will not only automatically operate the light, but is is so arranged that it automatically adjusts itself during the different seasons of the year to accommodate its action to the swelling or shrinking of the door.

Ward Leonard Motor-Starters.

The apparatus made by the Ward Leonard Electric Company, Bronxville, N. Y., have always been of great interest to contractors. This company manufactures so many devices which enter into in-

Ward Leonard "AS" Motor Starter.

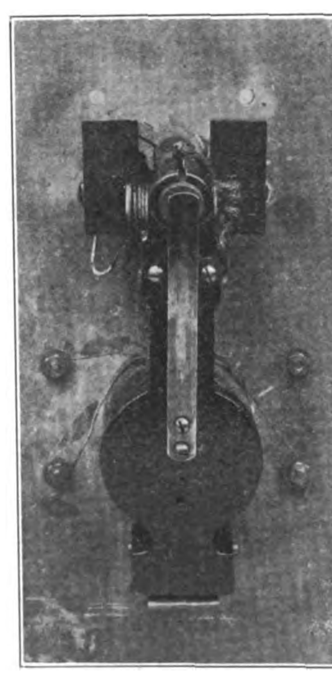


Tank Switch for Open Tank System.

stallations of every character and size that its name has long been familiar to the contracting fraternity.

The company announces recent advances in the design of automatic motor-starters and devices for regulating them, namely: Push-buttons, pressure regulators, tank switches, etc. Among the devices to which particular attention is called at the present time is the "AS" type motor-starter. This is a self-starting rheostat with a no-voltage release. This starter is for use in small sizes with main-line tank switches, and in any size with start and stop push-buttons. One of the illustrations herewith shows a self-closing switch operated by push-buttons. The combination of this switch and the "AS" starter, when mounted on one panel, forms a "CS" type self-starting rheostat with no-voltage release, equipped with a self-closing switch and a protective interlock, preventing the closure of the self-closing switch except when the resistance-controlling element is in the "all resistance in" position.

The "CS" type starter, when used with the pressure regulator, an illustration of which is shown herewith, is adapted to motor-driven pumps, etc.



Self-Closing Switch Operated by Push-Button.

The special feature in the design of this special line of apparatus is that the resistance units consist of Ward Leonard enameled units, the resistance element being thoroughly protected from any mechanical, electrical or chemical depreciation.

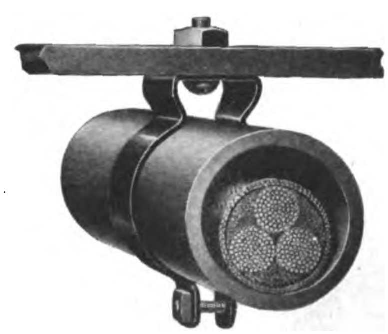
The self-starter is truly aligned, all the machine work being done at one time,

Pressure Regulator.

positively assuring that the dash-pot, plunger and magnet core are in perfect alignment. The company is giving the utmost attention to these details, and maintains an enviable position in the market by the honesty of the claims which it makes for its apparatus.

Minerallac Conduit and Cable Hangers or Cleats.

The accompanying illustration shows a cable and conduit hanger which has been placed on the market by the Minerallac Company, Monadnock Block, Chicago, Ill. These hangers are made of the best spring steel, and are easily and quickly put in place. Open wiring conduit and cable may be run with great rapidity and very compactly arranged. The hangers have been approved by the Underwriters' association for use on circuits up to 300 volts, when mounted direct on the surface



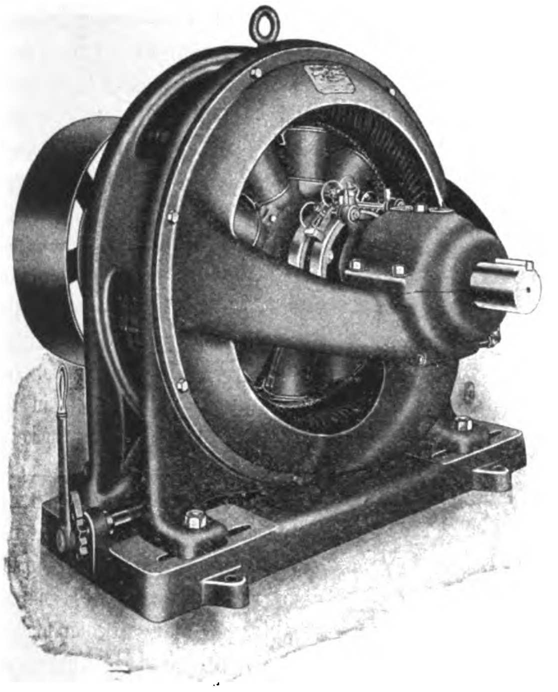
Minerallac Conduit and Cable Hanger.

wired over. For voltages from 300 to 550 the hangers must be installed with spacers under the base of the hanger or mounted on metal racks or brackets so as to hold the conductors at least one inch from the surface wired over. For voltages above 550 the hangers should be used with an appropriate insulating bushing having necessary insulation and dielectric strength, the hangers being mounted on metal racks or brackets to hold the conductors far enough from the surface wired over to preserve the required electrical clearance.

The company is prepared to furnish all styles of these bushings for high-tension work, properly designed to afford the necessary insulation and mechanical strength.

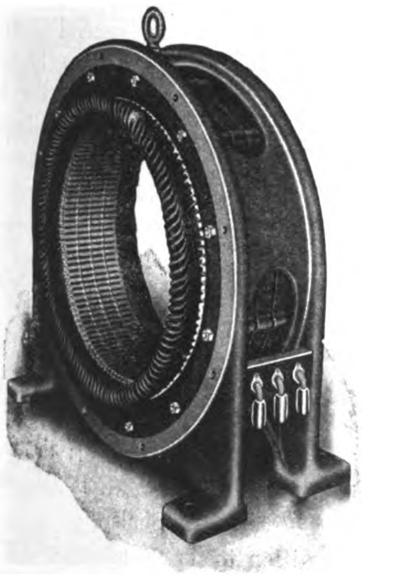
Fort Wayne Multi-Phase Belted Alternators.

The Fort Wayne Electric Works, Fort Wayne, Ind., has placed on the market a new line of multi-phase, sixty-cycle, revolving-field alternators of the belted type. These are styled TRB three-phase and QRB two-phase.



Fort Wayne Type TRB Three-Phase Belted Alternator.

These alternators are cheap, not through lack of material or through poor workmanship, but because of the reduced number of poles and the resultant speed, which permits the use of the minimum amount of material needed for the given output. The material is all of the highest quality,

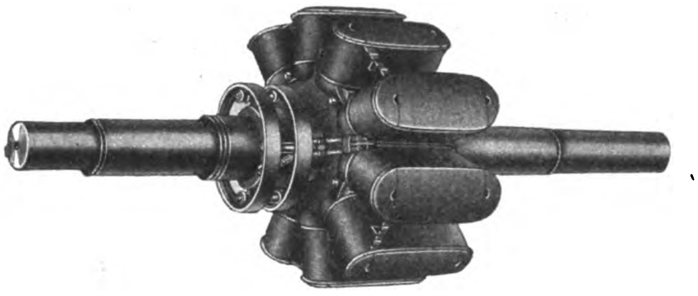


Frame of Fort Wayne Form B Alternator with Armature Winding.

and is handled by the most approved methods. The bearings are ample and cool-running, provided with oil-rings and reservoirs of ample capacity. They are supported by tripod brackets cast upon the end shields, giving great rigidity, with free access to the collector rings. The general appearance of this machine is well shown in the accompanying illustrations.

The alternator frame is of cast iron, in two parts, accurately machined and bolted together through the laminations of the armature core. The laminations are in sections and of special shape, having inwardly projecting teeth and projections extending out from the usual symmetrical outside circumference. In these projections are punched the holes through which the bolts pass, clamping the core and the two halves of the field frame firmly together. Air spaces are provided at the ends of the core and between laminations at regular intervals, to take advantage of forced ventilation produced by the fanning effect of the revolving field when the machine is in operation. An additonal advantage is taken by having the entire outer surface of the core exposed to the air.

The coils are carefully wound with highest-grade copper and insulated by superior methods of insulation. They are held in place by wooden wedges driven into grooves in the slots.



Revolving Field of Fort Wayne Form B Alternator.

The revolving field of the form B alternator is made up of a number of poles fitted into a central laminated spider with a dovetailed joint and taper keys to hold them firmly in position. After the poles are inserted in the special spider, end plates are bolted to each end of the core, closing up the joints. The poles are built up of laminations punched accurately from high-grade material and assembled under pressure.

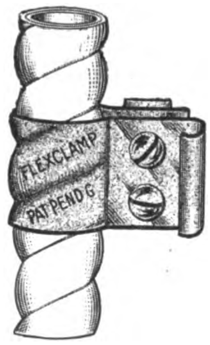
The collector rings are made of cast iron and have ample carrying capacity. Carbon brushes are used, held by the most improved type of brush-holder.

The form B multi-phase belted alternators are made with either two-phase or three-phase windings, for 2,300, 1,150, 600, 480 and 240 volts.

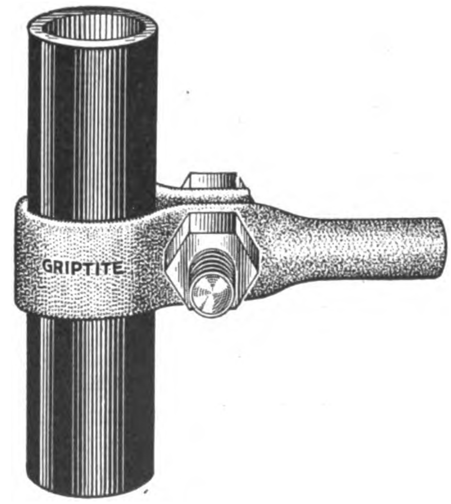
Belted exciters are furnished for all form B alternators. These exciters are known as the Fort Wayne type ML, and are belted to a small pulley mounted on an extension of the alternator shaft on the collector end.

Ground-Connection Clamps.

The Novelty Electric Company, 50-54 North Fourth street, Philadelphia, Pa., is calling attention to its "Griptite" and "Flexclamp" ground - connection clamps. The "Griptite" ground - connection clamps are for rigid conduit, and are made of rolled copper tubing in sizes to conform to the exact diameter of standard pipe from one-half to four inches. Being made of one piece of copper, the tightening of the bolt insures a perfect electrical contact



"Flexclamp" Ground-Connection Clamp.



"Griptite" Ground-Connection Clamp.

at all points on the pipe. The clamps have rounded edges, so that no possible injury can result to the lead casing of the cables when used for grounding these. The hollow tube to which the ground wire is soldered takes any size of copper wire up to and including No. 4 Brown & Sharpe gauge.

The "Flexclamp" is used for grounding Sprague flexible conduit and BX conductors. These clamps are made to fit perfectly the helical construction of the conduit. They are made of one piece of copper, and the tightening of the bolts insures a perfect electrical contact. There are five sizes—Size A, for No. 14 and No. 12 BX-2 conductors, No. 14 BX-3 and three-eighth-inch flexible conduit; size B, for No. 10 BX-2 and 3 conductors, No. 12 BX-3, No. 12 and No. 14 BXL, and No. 12 and No. 14 BM conductors; size C, for one-half-inch flexible conduit; size D, for three-quarters-inch flexible conduit, and No. 4 BX-2 conductor; size E, for one-inch flexible conduit.

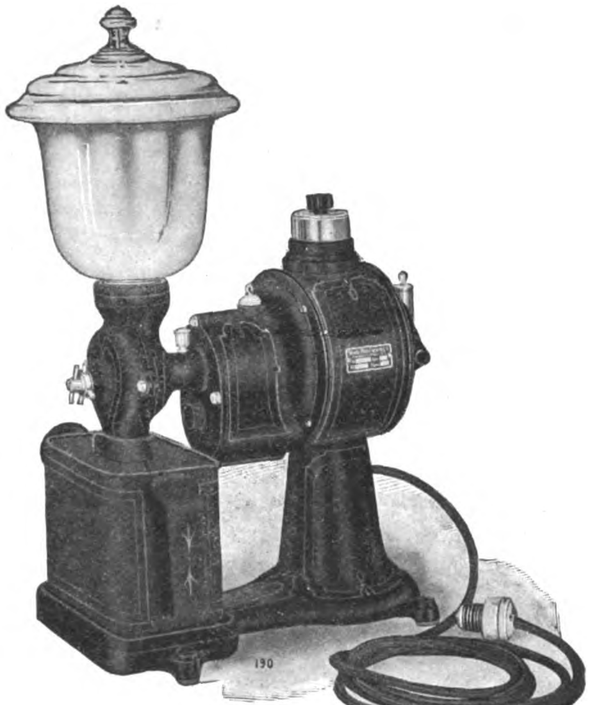
The Safety Armorite Conduit Company.

The Safety Armorite Conduit Company, Pittsburg, Pa., is the sole manufacturer under United States patents of "Loricated" and "Galvaduct" iron-armored conduits for interior construction. These conduits have found a very wide use in construction work of every character in all parts of the country. Among the important buildings in which these conduits have been exclusively installed are the following: Marshall Field Building, Commercial National Bank Building, Chicago, Ill.; Washington Terminal, Baltimore & Ohio and Pennsylvania Lines, Washington, D. C.; City Investing Building, Trinity Corporation and Annex, Hudson Terminal Buildings, Hotel Plaza, New York city; Carnegie Institute and Library, Pittsburg, Pa.; H. H. Rogers Memorial Church, parsonage, parish house and high-school group, Fair Haven, Mass.; Naval Academy buildings, Annapolis, Md.; Salt Lake Security and Trust Company Building, Salt Lake City, Utah; Denver Dry Goods Company, Denver, Col.; United States Military Hospital, Presidio, Cal.; Singer company's factories, Elizabethport, N. J.

In addition to the widespread use of these conduits in this country they have been exported for use in England, Canada, Australia, New Zealand, West Indies, the Philippine Islands, Hawaiian Islands, Mexico and the South American republics. These conduits are also installed in the majority of the warships of the United States built in recent years and in a large number of pleasure and merchant ocean-going vessels.

The Diehl Electric Coffee Mill.

The Diehl Manufacturing Company, Elizabethport, N. J., to meet a general demand for an electric coffee mill adapted to the needs of grocers, hotels, boarding houses and other users of coffee in large quantity, and which could be sold at a low price, has produced a low-priced electric coffee mill which at the same time is reliable, efficient and economical. As a maker of first-class electrical apparatus the company needs no introduction. Its large experience in the manufacture of thousands of small motors for driving fans, sewing-machines and other apparatus, places it in a unique position to supply a motor the qualities of which are unquestioned.



Diehl Electric Coffee Mill.

The general appearance of the mill as well as the arrangement of details is shown in the accompanying illustration. The grinder, gear case and back cover are combined in one unit, giving rigidity and compactness. The hopper is of spun brass, provided with a spun-brass cover, and both are heavily plated with nickel highly polished. The motor base is extended to hold the receiver, making the entire combination entirely self-contained. The mill may be readily adjusted to give any desired degree of fineness by means of a thumb-screw regulating the distance between grinders. The motor is provided with a switch for starting and stopping, and has ten feet of flexible cable attached. When the mill is put in service all that is necessary is to connect the plug to a convenient light socket and turn the switch.

The Doubleday-Hill Electric Company.

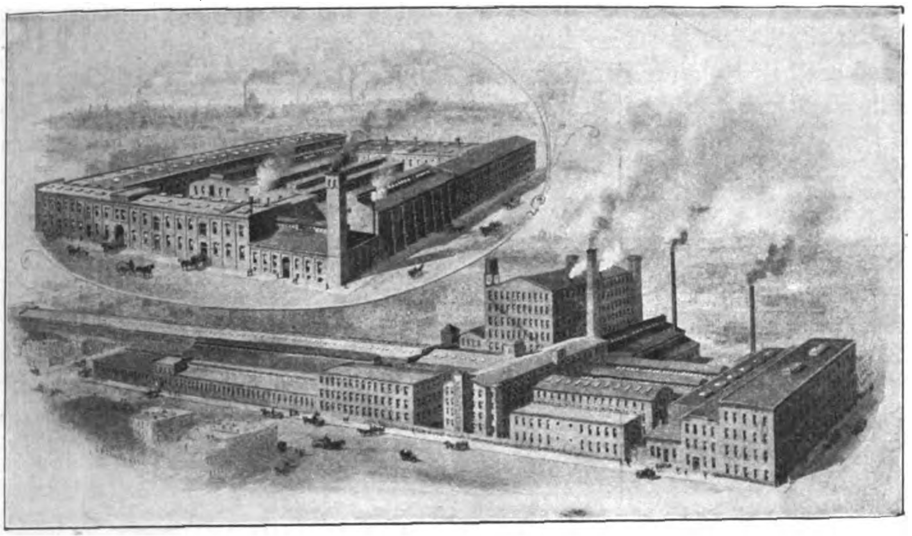
The Doubleday-Hill Electric Company, at 919 Liberty street, Pittsburg, Pa., is one of the largest electrical supply houses in the world. This company began business in one room in the Lewis Block ten years ago. The present business home of the concern is in a handsome building with eight floors, aggregating more than 50,000 square feet of space. In addition to the home office the company has two large auxiliary warehouses for the storage of surplus stock, and maintains a large branch supply house at Charlotte, N. C. The most interesting feature of this company's business is its large repair and winding shop, one of the busiest and most thoroughly equipped in point of labor and machinery to be found in the country. The company makes a specialty of the rewinding and repairing of all makes of both machine and hand-wound armatures. In its repair shop the company also refills, reinsulates and assembles all makes of commutators, and is prepared to furnish all necessary new parts for any of this apparatus, as well as arc lamps and, in fact, anything electrical that requires repairing. The company manufactures commutators, field and armature coils, switchboards, trolley wheels, and in the past has made quite a variety of special electrical equipment. In addition to the manufacturing and general distributing features of the business the company is sole agent for the Excello flaming arc lamp, A.-B. arc lamps, and includes among its exclusive specialties "O. K." weatherproof wire and cables, Triumph dynamos and motors, Emerson alternating fans and motors, Adams electric rock drills, Packard transformers, G. E. dynamos and motors.

The company is incorporated under the laws of the state of Pennsylvania with an authorized capital of $300,000. The president is C. Phillips Hill; the vice-president and treasurer, G. B. Hill, and the secretary, H. G. Shaler.

In addition to its comprehensive repair shops, factory and storehouses, the company has developed a business and office system which minimizes delays and facilitates the selection of material, and insures prompt shipping and tracing of all orders. The company maintains a large corps of traveling representatives and handles the largest orders placed in this field.

The Waterbury Company.

The Waterbury Company, with offices at 80 South street, New York city, and factories in Brooklyn, N. Y., is one of the largest manufacturers of seamless rubber-insulated wire and cables; paper-insulated, lead-encased cables; railroad signal wires, lamp cord, and flexible cords, as well as manila and sisal rope, oil-well cordage, wire rope, and music wire. The company was established in 1816, and commenced the manufacture of rubber-covered wire, telephone wires and special cables three years ago. Since the opening of this plant business has steadily increased until the company is now counted as one of the foremost manufacturers of this product.



THE BROOKLYN, N. Y., WIRE AND ROPE MILLS OF THE WATERBURY COMPANY.

The accompanying illustration shows the rubber-covered wire mill and the other mills operated by the company. Branch offices are established in Chicago, Pittsburg, New Orleans and San Francisco.

The Crouse-Hinds Condulets.

The development of condulets by the Crouse-Hinds Company, of Syracuse, N. Y., is being watched with much interest by all who are concerned with wiring propositions. The simple device, in most types, consisting of but two pieces, a cast shell and a cover, has simplified the conduit construction in such a marked degree that it is fast gaining the title of the "Key to Conduit Construction." The fittings are very simple in design, which point, together with the general neat appearance, occasions many conduit installations that would not have been undertaken in time past.

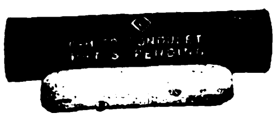
Condulets are made in many styles; in fact, it can be truthfully said there is a style for practically each and every requirement that may occur in any conduit or combination conduit and molding installation.

The illustrations which are shown herewith represent a type "A" and "C" fitting. The castings are provided with one or more threaded hubs, according to the type, into which the conduit is screwed. This form of construction insures con-

TYPE "A" CROUSE-HINDS CONDULET.

tinuity of conduit system, an important feature, and at the same time requires no more time to install than that involved in running a nut on a bolt or a nipple on a pipe.

It is not necessary to run the wires until the system is completed, as they can be drawn through the conduit to the condulets whose function is the same as that



TYPE "C" CROUSE-HINDS CONDULET.

of a manhole in a large conduit system. The covers are fastened to the castings and wires are drawn through, taps having been made, if branch wires are desired at this point. Blank metal covers are generally used where no branches are taken off. There are numerous styles of covers provided with standard nipples; also some types are provided with adjustable plates, so that fixtures, switches and various fittings can be mounted thereon.

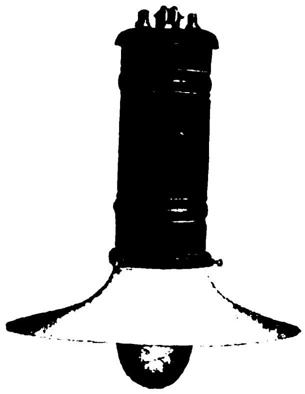
The type and location of condulets in any system are determined by the requirements of the wiring plan.

The Aurora Miniature Arc Lamp.

The Aurora Electric Company, Aurora, Ind., has placed on the market a miniature direct-current arc lamp. This lamp is simple in construction, substantial and neat in design. The resistance coil is mounted within the case, and the inner globe and guard are held in position by compression springs and permit of easy removal without the use of tools. The carbon feed works automatically, preventing burning out of the lower carbon holder. The maintenance costs are low, and an ordinary workman can easily trim the lamp.

The lamp has a consumption of two amperes at 125 volts, one and one-half amperes at 250 volts, and the carbons have a life of thirty hours.

A steady, pure-white light equaling fifty ordinary incandescent lamps is given, the current consumption being the equivalent of four incandescent lamps. The lamp



AURORA MINIATURE ARC LAMP.

is fifteen and one-half inches long by four and one-half inches in diameter. The weight complete, including porcelain shade, is seven pounds. The case is made of polished brass, or is given an oxidized metal finish. The lamp is especially adaptable for store windows, stores, halls, theatres, factories, etc.

The Aurora Electric Company is the manufacturer of an electromagnetic socket, which, by means of magnetic attraction to iron or steel, will hold an incandescent lamp in any position, allowing the light to be applied directly where desired. It can be used in any place or position where there is an iron or steel surface. It holds the lamp firmly and can be applied instantaneously.

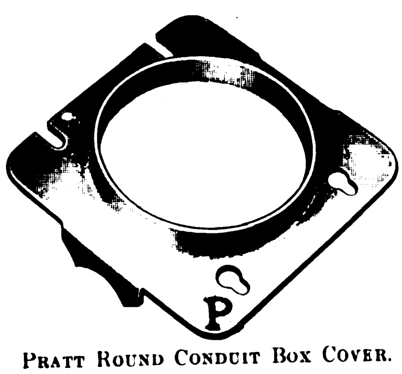
Galvanized Stamped-Steel Outlet Boxes and Covers.

The Pratt Chuck Company, Frankfort, N. Y., is the manufacturer of a fine line of galvanized stamped-steel outlet boxes and covers. Included in this line is a box for combination gas and electric fixtures, shown in the accompanying illustrations. This box is four inches square and one and

PRATT GALVANIZED SEAMLESS CONDUIT BOX.

five-eighths inches deep. It has eight conduit outlets in the sides and five in the bottom. There are two gas outlets, one in two opposite sides, for one-half-inch gas pipe only. The other side outlets are for one-half-inch or three-quarters-inch conduit only. The boxes are also arranged for gas elbows.

Other boxes which this company manufactures are the BA switch outlet or junction box, the CA outlet and junction box,



PRATT ROUND CONDUIT BOX COVER.

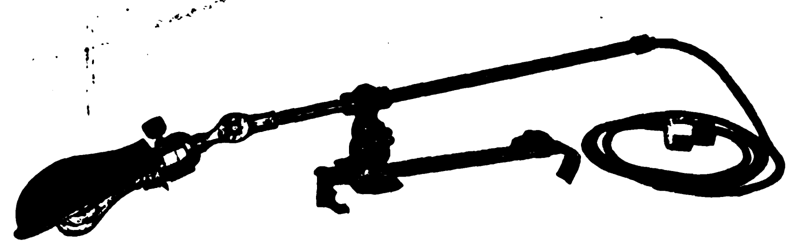
which is a round box four inches in diameter and one and five-eighths inches deep. The DA deep outlet and junction box for lath and plaster is four inches in diameter and two and one-quarter inches deep. This is equipped for four outlets in the sides and five in the bottom. The side outlets are for one-half-inch, three-quarters-inch and one-inch conduits. The boxes are drilled for fixture stems, and the flat steel cover is drilled for standard ten-ampere rotary snap switch. Other boxes are the EA box for G. E. receptacle No. 50,746 and for Bryant receptacle No. 5,050; the GA box, equipped for Norbitt, Trumbull, "P. & S." and G. E. receptacles. The company furnishes steel or polished-brass covers for Federal sockets and rotary snap switches in connection with its FA and CA boxes.

The HA, IA and KA boxes for ceiling outlets in terra-cotta are four inches or five and one-half inches in diameter, one-half inch or three-quarters inch deep.

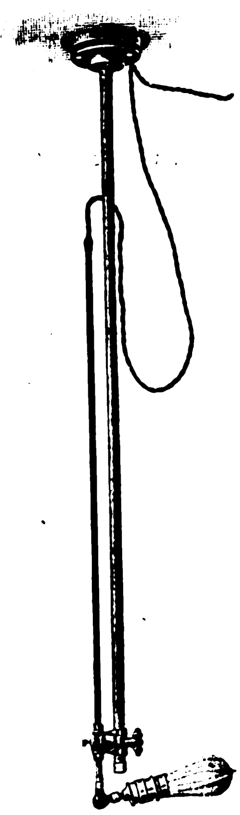
Adjustable Fixtures for Incandescent Lamps.

The O. C. White Company, Worcester, Mass., is the manufacturer of a very extensive line of standard adjustable fixtures for incandescent lamps for shops, mills and factories, drafting rooms, offices and banks, for residences, libraries and dressing rooms. These are made in plain forms and in combination with gas fixtures. These fixtures are strongly constructed and designed to withstand hard usage. They are constructed of iron and gun metal, and are listed in a variety of finishes to harmonize with the hardware and fittings generally used. The plain black finish is best adapted for shop fixtures. The plated finishes are frequently used where fixtures of rugged construction are required for offices, libraries, banks and well-appointed drafting rooms. The fixtures have been revised and approved, and can be wired easily and quickly with New Code wire. The arms are all straight and true and slide and turn freely to any adjustment.

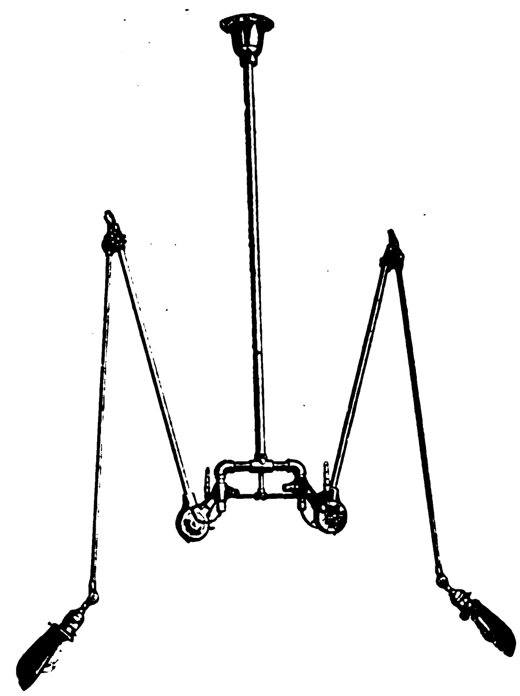
The ceiling fixtures are fitted with ball and socket base joint, swiveling and sliding cone joint and wrist joint. This adjustability permits of turning the lamp instantly into any desired position, and gives perfect protection to the cords and lamps among moving and shifting belts in shops and factories.



WHITE STRAP-CLAMP DESK LIGHTING FIXTURE.



WHITE ADJUSTABLE LIGHTING FIXTURE.

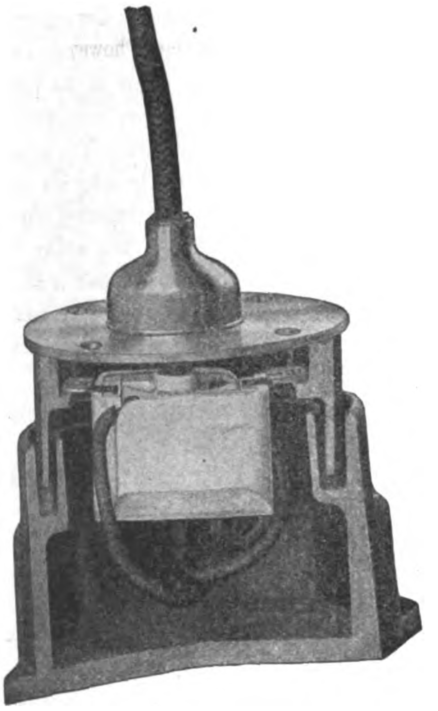


WHITE ADJUSTABLE LIGHTING FIXTURE.

One of the latest designs is the strap-clamp desk fixture. This is made for direct attachment to a roll-top desk. The main joint embodies entirely new mechanical principles and permits turning, tipping and sliding adjustments to any position or angle by frictional tension secured at one point or fastening. The standard wrist joint at the end of the lamp gives free angular adjustment to the lamp.

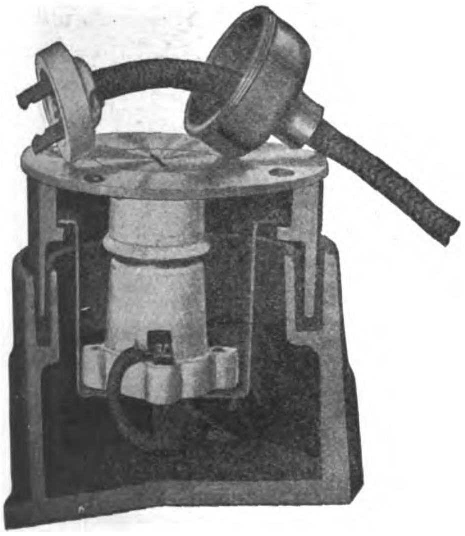
Fullman Water-Tight Outlets.

One of the popular specialties manufactured by the Steel City Electric Company, of Pittsburg, Pa., is the Fullman water-tight floor outlets. The accompanying illustrations will indicate better than



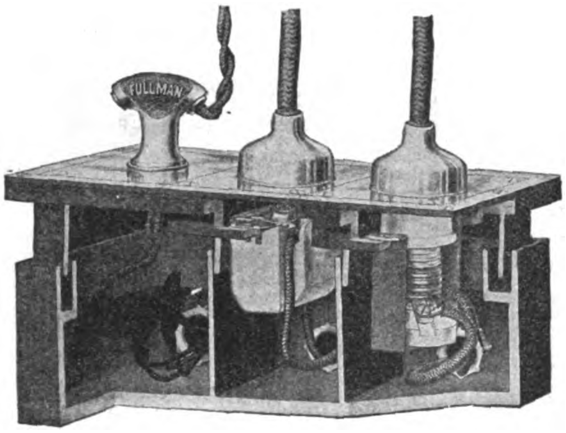
Sectional View of Fullman Floor Outlet, with Bell Nozzle.

a lengthy description the adaptability and utility of these devices. The apparatus is moisture-proof, and the universal tilting adjustment water-tight feature is peculiar to the Fullman designs. The floor plate is always flush and even with the floor, and alignment of receptacles is always correct, regardless of the crooked setting of the box body. One of the illus-



Fullman Box with Hubbell Attachment.

trations herewith shows a sectional view of the four-and-three-quarters-inch box with a bell nozzle and standard flush plug receptacle. Another illustration shows the same box with a Hubbell plug and a two-inch flush brass plug closing the opening in the floor plate. Still another illustration shows a sectional view of a rectangular gang box of three sections, showing a "drip" nozzle in use, a bell nozzle in use, and a two-inch flush

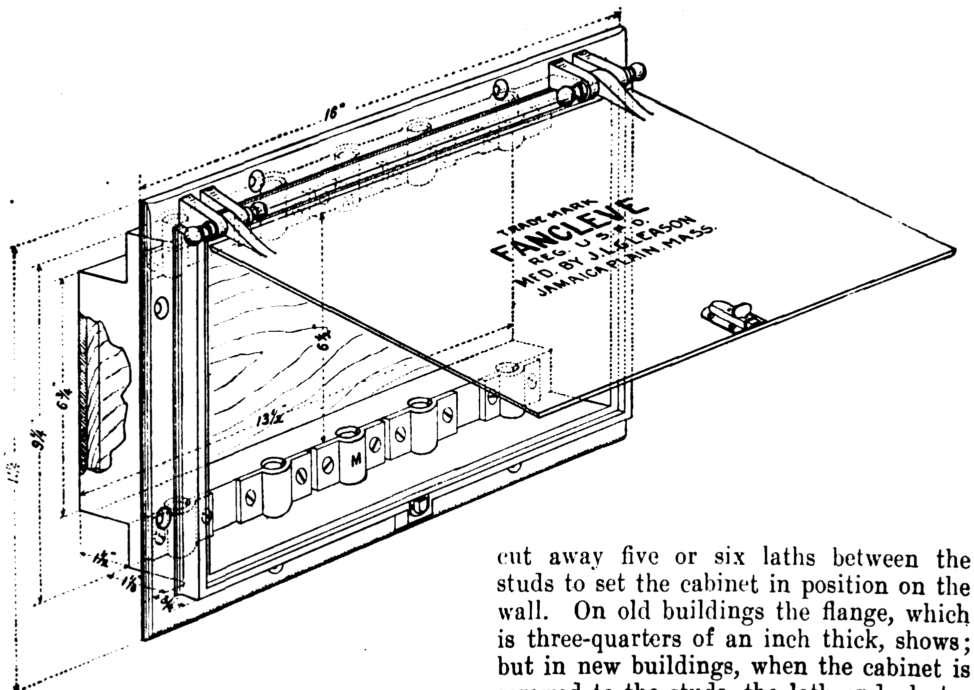


Sectional View of Fullman Rectangular Gang Box.

brass plug closing one opening. These gang boxes are furnished in two, three, four, five and six sections. The minimum height to the top of the cover is four and one-quarter inches.

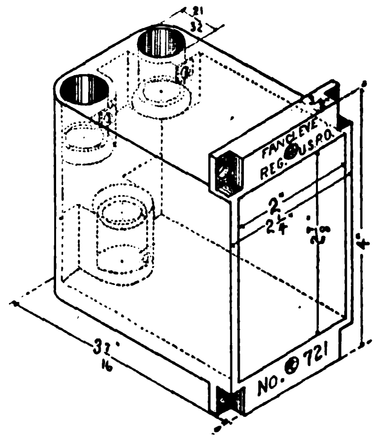
Some New "Fancleve" Specialties.

John L. Gleason, of Jamaica Plain, Mass., patentee and manufacturer of "Fancleve" specialties, has recently placed on the market two new fittings for use



New "Fancleve" Cutout Cabinet.

with Greenfield BX armored cables in old buildings. One of these fittings is a switch box which is made in sizes from one to four gangs and will fit any standard switch or receptacle. The cable pockets have a shoulder at the inside end to check the armor of the cable, and the surfaces through which the conductors project are rounded to prevent abrasion or chafing of the braid. A suitable plug is supplied in every pocket but one in each



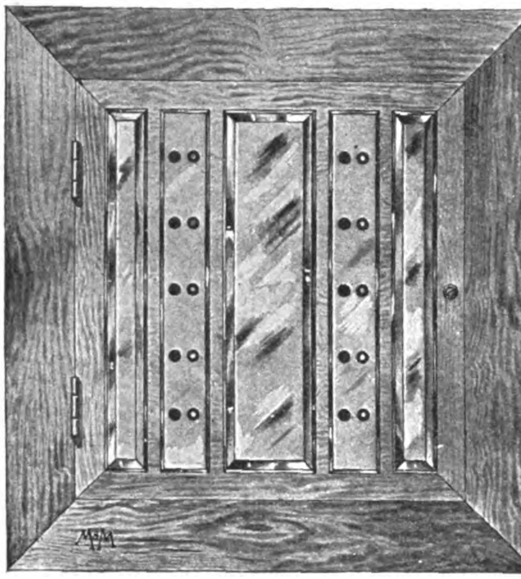
New "Fancleve" Switch Box.

box, so as to seal it if the pocket is not used.

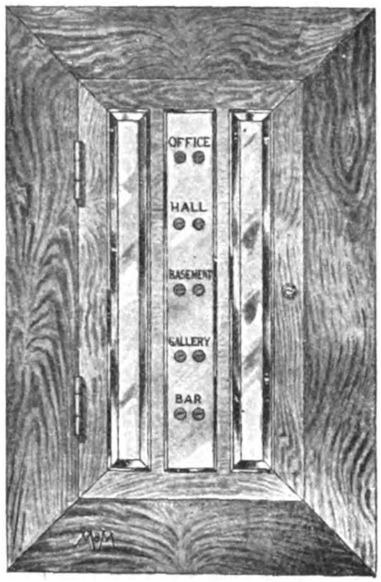
The other fitting is a cutout cabinet with a capacity of eight circuits. Four circuits enter at the top and four at the bottom. There are two entrances for the mains, opposite each other, and designated by the letter "M." The pockets are reamed to confine No. 8 or No. 10 cable, and the branches are reamed to take No. 12 or No. 14 cable. It is intended that the cables be brought up or down partitions between the studs, and the cabinet is of such a size that it is only necessary to cut away five or six laths between the studs to set the cabinet in position on the wall. On old buildings the flange, which is three-quarters of an inch thick, shows; but in new buildings, when the cabinet is screwed to the studs, the lath and plaster come out flush with the edge of the cabinet. The fitting is of iron, excepting a beading of half-inch hardwood to which the cutouts are fastened. The door raises upward, so that it tends to stay closed through the action of gravity. The fitting weighs about twenty-four pounds.

"M. & M." Panel-Boards.

The Machen & Mayer Electrical Manufacturing Company, Twelfth and Buttonwood streets, Philadelphia, Pa., has placed on the market a new type of panel-board known as the "M. & M." panel-boards of

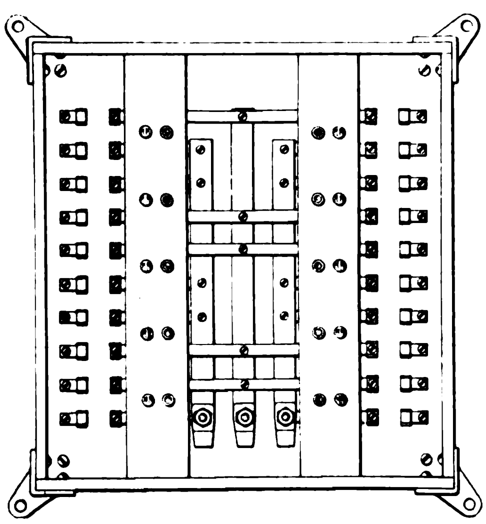


FLUSH TYPE OF "M. & M." PANEL WITH PUSH-BUTTON SWITCHES.



FLUSH TYPE OF "M. & M." PANEL WITH LOCK SWITCHES.

the push-button switch type. These panel-boards are very handsome in appearance, and are adapted to the highest class of installations. They are made in several different types. The cabinet type is adapted to use in any ordinary panel cabinet of the proper size. This type is divided into two classes, one operated by



CABINET TYPE "M. & M." PANEL.

push-button switches and the other operated by lock switches. The flush type of panel-board is furnished with door and trim. The difference between this type and the cabinet type is in the door and trim, the door having openings in it, allowing the switch face-plate to extend through, so that the switches can be operated from the outside without opening the door. This type of panel is also divided into two types, one using push-button switches, and the other lock switches.

There is no danger of the operator coming in contact with any live parts. The brass face-plate over the switches serves as a convenient directory of the various circuits.

To replace a defective switch it is not necessary to disturb the panel-board or other switches, as any switch can be replaced from the front of the panel.

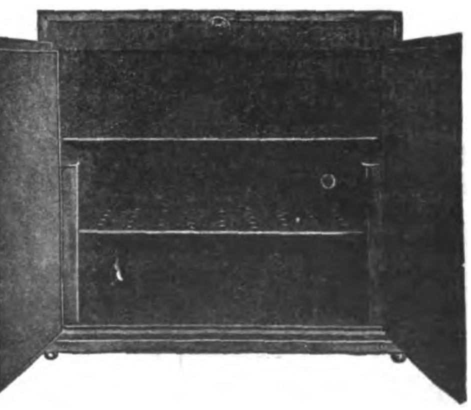
Where panel-boards are located in hallways, in public buildings, or in places where it is desirable to have the lighting circuits under the control of either the superintendent of the building or some special attendant, the lock-switch type of panel-board offers the advantage that the lights can not be turned on or off except by the attendant with a key specially designed to operate the switches.

The flush type of panel is two and one-half inches deep, while the cabinet type is three and one-half inches deep. Either of these types of panel can be made with meter loops and with four bus-bars for use on two-phase circuits; also with knife switches in the mains if desired. The Underwriters' specifications are followed in every respect in the construction of these panel-boards, and the "M. & M." shallowest flush push-button switches used in their construction have been tested and approved by the Underwriters.

The Prometheus Electric Plate-Warmer.

The electric plate-warmer is not, strictly speaking, a new device. Plate-warmers have been made for several years, and hundreds of them are in use, particularly in the large cities. Contractors outside of New York city, however, are probably not sufficiently alive to the possibilities for profitable orders represented in this branch of the business. The arguments in favor of electric heating are too well known, and have been repeated often enough, to be omitted. It will suffice to say that the electric plate-warmer is eminently convenient, no matter where used, and is a necessity wherever meals are served and electric current is available.

The accompanying illustration shows an electric plate-warmer made by the Prometheus Electric Company, 236-238 East Forty-third street, New York city. These plate-warmers are heated by means of individual electric resistances attached to the sides on the inside of the plate-warmer, and covered with flues which project but one inch into the interior of the apparatus. The electric equipment, therefore, takes hardly any room and economizes greatly in space over those plate-warmers which use gas or steam pipes for producing the heating element. This apparatus has been pronounced a very practical equipment. The arrangement of the resistance units insures a continuous



THE PROMETHEUS ELECTRIC PLATE WARMER.

circulation of heated air, and the entire inner space is heated to a uniformly high temperature.

These plate-warmers, as a rule, are made to architects' specifications, and for this reason are built to order only. Russia iron is used in the construction, and the double walls are mounted on an angle-iron frame. The intervening space is lagged with mineral wool or asbestos.

Bishop Gutta-Percha Company.

During the past year the factory of the Bishop Gutta-Percha Company, 420-430 East Twenty-fifth street, New York city, has been entirely remodeled and considerably enlarged. A new building, five stories in height and covering a plot fifty by 100 feet, has been erected adjacent to the old factory building. Special attention has been given to lighting and ventilating, it having windows on all sides. Pains have been taken in the matter of fire protection, the first two stories and basement being of up-to-date fireproof construction and the building equipped with automatic-sprinkler system, having both gravity and pressure tanks.

The power plant for the entire factory is located in the basement of the new building and all machines are now driven electrically, using a two-phase alternating current with a potential of 220 volts.

The buildings are well lighted with Nernst lamps, so that in case of necessity work can be done at night as well as day. New insulating and braiding machines of the latest type, as well as a modern lead press, have been installed. With new machinery and increased floor space, the facilities for manufacturing both rubber-covered wire and gutta-percha goods have been increased from sixty to seventy-five per cent.

The business of this company was established for the manufacture of gutta-percha goods in 1847, which has been carried on continuously ever since.

The plant for rubber-covered wire was installed early in the eighties, and the company has ever since made a specialty of high-grade insulated wires and cables, furnishing a considerable number of submarine cables for telegraph, telephone and power service, as well as gutta-percha insulated cables for submarine use.

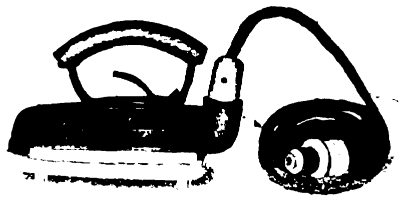
The Bishop standard high-grade wire, elevator control or traveling cables, annunciator and lighting cables and the asbestos-covered car cables of this company's make are well known throughout the country.

In the new building is installed an up-to-date testing laboratory with electrical testing set for high voltages and insulation resistance. The company is continuing to manufacture, as it has since 1847, all kinds of gutta-percha goods.

The president of the company, Henry A. Reed, who entered the telegraph field in 1849, has been nearly thirty years engaged in the Bishop factory, during which time he has been considered a leading authority on electrical insulation, is still active in the business, having associated with him in its management two of his sons, Henry D. Reed, M.E., Stevens, 1892, who has been engaged in the business for the past fifteen years, and W. Boardman Reed, C.E., Union, 1882, treasurer of the company, who was for many years connected with electrical railway work.

Economy Electric Heating Apparatus.

The Economy Electric Company, 217 Fulton street, Brooklyn, N. Y., is placing on the market a number of useful elec-



Economy Electric Flat-Iron.

trical heating and cooking devices, including soldering and branding irons, flat-irons and other heating specialties. The Economy electric soldering and branding irons are made for all standard voltages.

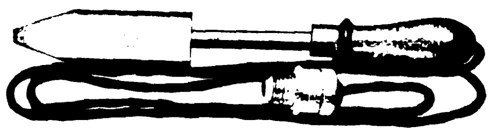
Component Parts of Economy Electric Flat-Iron.

The irons are constructed to meet the necessary requirements of the Board of Fire Underwriters, being made of the best approved material. The principle and construction of these irons are such that all the heat is concentrated in the copper, preventing the wasting of electrical energy due to the heating of shells and casings.

One of the illustrations herewith shows an electric soldering iron for medium work. This size and style is best adapted for work in shops, buildings, garages, yachts, and is serviceable for soldering connections and for making up string lights for stage lighting. This iron consumes 150 watts.

The branding iron shown herewith consumes 350 watts and is designed to meet all the necessary requirements for branding provisions in packing houses under the new inspection laws. Other forms of iron are made for soldering telephone and telegraph connections and for work in obscure places. This form of iron consumes seventy-five watts. Another iron consuming sixty watts, and still another consuming 100 watts, are made for light work. Other irons consuming 200 watts and 300 watts, and a heavy iron consuming 400 watts, are also available.

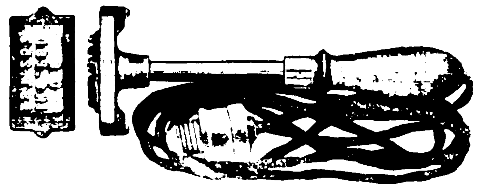
The Economy electric flat-iron, shown herewith, is equipped with a flat mica disc wound with a heating element of exceptionally long life. The company guarantees that its goods, in addition to having a long life, are very economical in the consumption of current. The internal



Economy Electric Soldering Iron for Medium Work.

electric heater covers the entire bottom of the iron, thus heating the entire surface of the iron.

The iron is equipped with a removable handle. This is an important feature, as no current is consumed in heating the handle and no protecting pad is needed.

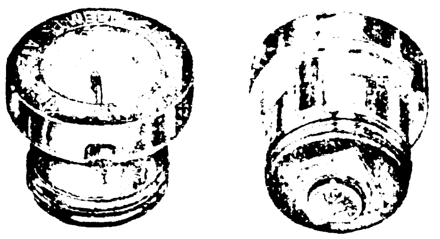


Economy Electric Branding Iron.

The handle is always cold because it can be removed when the iron is not being used.

Weber Fuse Plugs.

Henry D. Sears, 131 State street, Boston, Mass., general sales agent for Weber electric wiring specialties, announces the new Weber fuse plugs for 125 volts, with mica caps, illustrations of which are

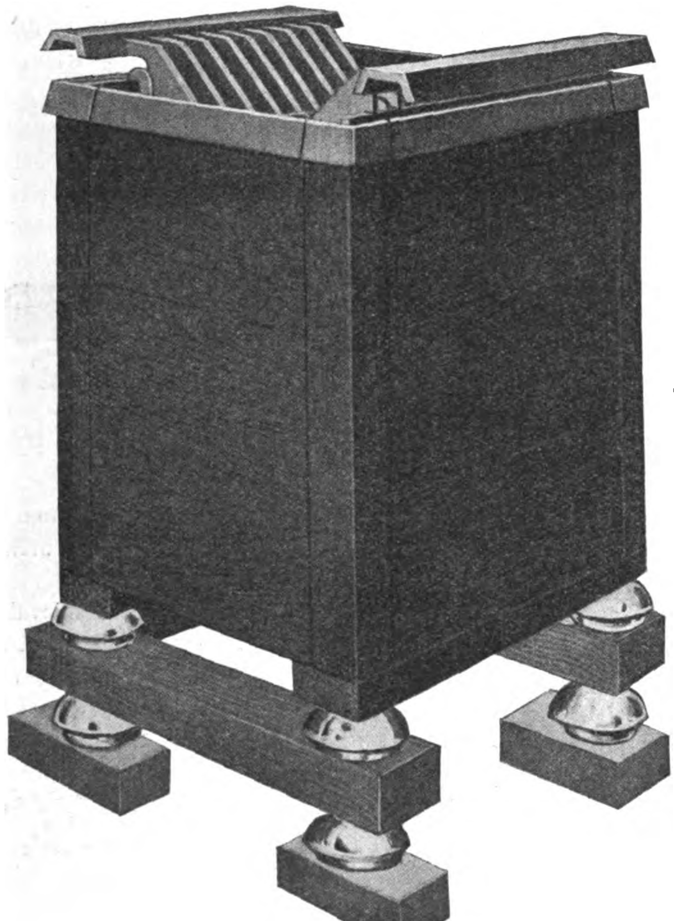


New Weber Fuse Plugs.

shown herewith. When the fuse blows there is no possibility of the escape of molten fuse metal; the large vent holes provide for the proper escape of gas, and there is no outside lump of solder to prevent proper bottoming of the plug in the cutout. These plugs are made in capacities from three amperes to thirty amperes.

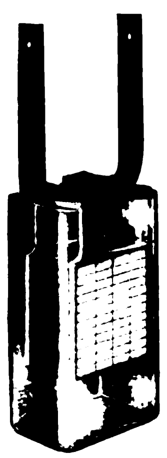
The Electric Storage Battery Company.

The Electric Storage Battery Company, Philadelphia, Pa., is the manufacturer of three general forms of storage



Type "G" Nineteen Plates in Lead-Lined Wood Tank.

batteries bearing the trade-marks respectively of the "Chloride Accumulator," the "Tudor Accumulator" and the "Exide Accumulator."



Type "B" Three Plates in Glass Jar.

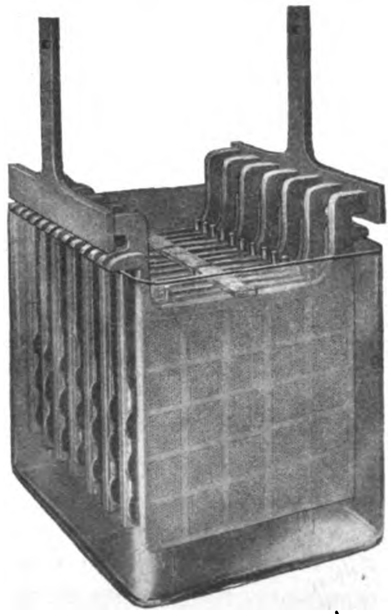
This product represents the highest development of this branch of the electrical industry. Installations of these batteries are not only found in general use throughout the United States but also in South America, Mexico and Canada.

The smaller cells of the "Chloride Accumulator," embracing the two-plate types and types B, C and D, are used where a small current capacity is required, thousands of these cells being operated for police and fire-alarm systems, telegraph, railway signals, laboratory service and for small isolated lighting plants.

The larger cells, embracing types E, F, G, R and H, are employed for lighting and power stations, street and interurban railway service, electrification of steam railroads, residential and isolated lighting, etc.

The "Tudor Accumulator" and the "Chloride Accumulator" are used in the special forms, designed by the company, for the electric lighting of railway cars. A complete description of these types is contained in a catalogue recently issued under the title of "Car Lighting Cells," Catalogue C.

The "Exide" battery is used principally for electric-vehicle propulsion and for the ignition of gas or gasolene engines in automobiles, power boats, stationary service, etc.

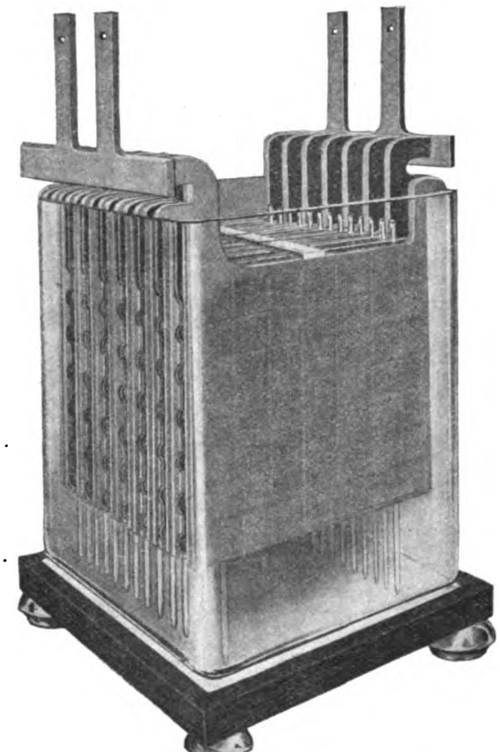


Type "E" Thirteen Plates in Glass Jar.

The extensive use of the "Exide" battery necessitated the opening of "Exide battery depots" in different cities, and about 400 "Exide distributors" throughout the country are prepared to supply and maintain "Exide" batteries and parts.

It has always been the policy of this company not only to produce the best batteries, but to devise instruments and furnish the required instructions for maintaining their cells in the best possible condition. To this end a force of operating engineers is employed in constantly superintending the working of batteries installed by this company, thus insuring their economical operation and efficiency.

The auxiliary apparatus and accessories



Type "F" Fifteen Plates Glass Jar.

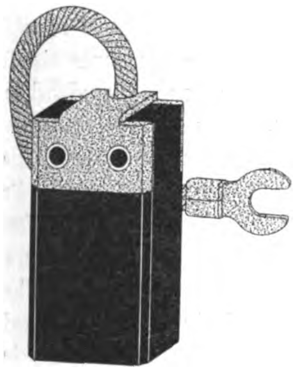
for use with storage batteries designed and constructed by this company are the result of twenty years' experience and the labors of an engineering force specially trained in battery work.

The company does a large business through electrical contractors in the installation of batteries in residential, mill, factory and similar isolated plants, and has issued bulletins especially covering these applications.

Portable "Exide" Battery.

The LeValley Vitae Carbon Brush with Pigtail Connection.

The accompanying illustration shows the new form of carbon brush which has been placed on the market by the LeValley Vitae Carbon Brush Company, 405 East Tremont avenue, New York city. The advantageous feature of this new connection is that it is indestructible. The copper plates to which the lead is attached are firmly clamped to the carbon on each side by expanded copper rivets, making a perfect contact. Solder does not enter in any way into its construction, and it can

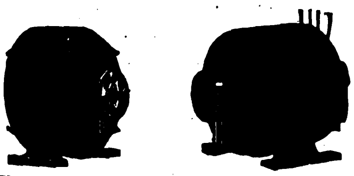


LEVALLEY VITAE CARBON BRUSH WITH IMPROVED PIGTAIL CONNECTION

not therefore melt off or become detached from the carbon. The brush maintains its even proportion throughout, fitting snugly in the brush-holder until the brush is worn out. This insures a perfect contact, and the brush can not tilt over. This invention is owned by M. W. Robertson, sales manager of the company.

Westinghouse Small Power Motors.

The small power motors supplied by the Westinghouse Electric and Manufacturing Company for either direct current or single-phase alternating current, are particularly compact and durable under all sorts of operating conditions. They are all automatic in their starting char-



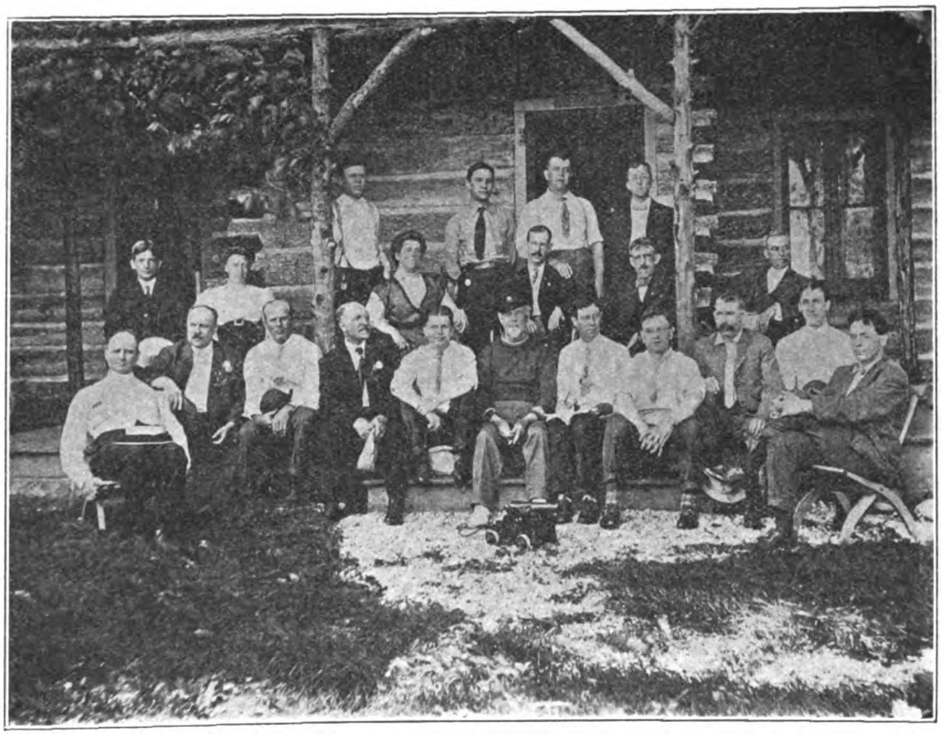
WESTINGHOUSE SMALL POWER MOTORS.

acteristics, as in starting it is only necessary to close the main switch. The motors will in all cases start full load and will stand considerable overloads.

The motors are manufactured regularly in sizes from one-twentieth to one-quarter horse-power, for either 110 or 220 volts in standard speeds. The illustrations show both the direct and alternating-current motors in the one-sixth-horse-power size. The motors are given a horse-power rating on an intermittent basis of full load for one-half of the time, with no period at full load longer than one-half hour. These motors are regularly manufactured for sixty and twenty-five cycles, although in some cases they are supplied for 133 cycles.

Annual Summer Conference of the Fostoria Incandescent Lamp Company.

The annual summer conference of the salesmen of the Fostoria Incandescent Lamp Company, Fostoria, Ohio, was held during the week of June 22 at Ballast Island, in Lake Erie, near Put-in-Bay. It was attended by about twenty-five rep-



ANNUAL SUMMER CONFERENCE OF THE FOSTORIA INCANDESCENT LAMP COMPANY'S SALESMEN, BALLAST ISLAND, LAKE ERIE.

resentatives from all parts of the United States, and an extensive programme of technical sessions and entertainment features was carried through. The meeting was pronounced a marked success, and it was especially important on account of the fact that this has been the first meeting held since all of the high-efficiency incandescent units have been commercially perfected.

The company's factory at Fostoria is now undergoing extensive alterations and enlargement. In addition to this, the construction is being strengthened throughout on account of the manufacture of tungsten lamps. Heavier material, including heavy maple flooring, etc., is being installed, and when this work is finished the factory will not only be practically as good as new, but have a considerably larger production and a correspondingly better equipment.

Meeting of the New York State Electrical Contractors.

The semiannual meeting of the Electrical Contractors' Association of New York State was held at Buffalo, N. Y., on June 22, 23 and 24. The programme included a meeting of the board of directors on June 22, a meeting of the general association, luncheon and banquet on June 23, and a private trip to Niagara Falls and inspection of the plants of the Niagara Falls Power Company, Hydraulic Power and Manufacturing Company, Canadian Niagara Falls Power Company, Ontario Power Company, Electrical Development Company of Ontario, with dinner at the Clifton Hotel, Niagara Falls, Ontario, on June 24.

For this semiannual meeting each of the various local contractors' associations send delegates or representatives. About thirty of these representatives were present. The total attendance was 110, and eighty members were present at the banquet.

The present officers of the association are: James Hilton, president, Syracuse, N. Y.; Edmond D. McCarthy, vice-president, Buffalo, N. Y.; George W. Russell, Jr., secretary, New York city; James F. Burns, treasurer, Schenectady, N. Y.

Civil Service Examinations for New York State and County Service.

The New York State Civil Service Commission will hold examinations on July 25 for the following positions: Assistant in economic geology, State Museum, $1,200; engineering examiner, Civil Service Commission, $1,000 to $1,200; leveler, $4.50 to $5 a day; structural engineer, state architect's office, $2,000.

The last day for filing applications for these positions is July 18. Full information and application forms may be obtained from Charles S. Fowler, chief examiner, Albany, N. Y.

The Society for the Promotion of Engineering Education.

The sixteenth annual meeting of the Society for the Promotion of Engineering Education was held at Detroit, Mich., June 24, 25 and 27. The address of welcome was delivered by Mayor Thompson. In the absence of President Howe the chair was occupied by Vice-President W. G. Raymond, of the University of Iowa.

Professor Dugald C. Jackson presented the report of the joint committee on engineering education. This committee is formed of representatives of the national engineering societies.

A paper was read by Professor J. Martin Telleen, of the Case School of Applied Science, on "The Course in English in Technical Schools." Another paper of the same nature was presented by Dr. William Kent, entitled "Results of an Experiment in Teaching Freshman English." Howard Frost presented a paper entitled "A Proposed Course in General Engineering." Professor W. T. Magruder presented a paper entitled "Present Curricula of the Mechanical Engineering Courses."

On Wednesday evening there was a joint session with the American Society of Mechanical Engineers, when a lecture was delivered by Professor Brashear on "Contributions of Photography to our Knowledge of Stellar Evolution."

The second session of the society was held on Thursday afternoon. The annual address of President Charles S. Howe was entitled "The Function of the Engineer in the Conservation of Natural Resources of the Country." A. L. Rice read a paper on adapting means to the end in technical education. A paper taking up the question of the place of foreign languages in the curriculum in schools of engineering was presented by Professor A. L. Wright. Professor W. F. M. Goss read a paper on second degrees for graduates of engineering courses. The subject of scholasticisms in engineering education was presented by John Price Jackson.

The Saturday morning session was devoted to a discussion of papers by Dr. Schneider, of the University of Cincinnati, and Professor Furman, of Stevens Institute of Technology.

Monument to John A. Roebling.

The entire city of Trenton, N. J., joined in paying tribute to the memory of John A. Roebling, founder of the John A. Roebling's Sons Company, Trenton's greatest industrial corporation, upon the occasion of the unveiling of a monument to Mr. Roebling at Cadwalader Park, on Tuesday, June 30. This magnificent tribute was the occasion of the dedication of the monument erected by the Roebling Memorial Association. During the afternoon practically all mercantile business in the city was at a standstill because of the gathering of thousands of people to witness the ceremonies. Preceding the formal dedicatory programme at Cadwalader Park there was a parade of 5,000 employés from the Trenton plant of the John A. Roebling's Sons Company and 1,000 from Roebling, N. J., the industrial town on the Delaware River which has been built up to carry on the overflow of the Roebling industry from the Trenton mills.

Colonel Mahlon R. Margerum was master of ceremonies. The first number of the set programme was the American overture by Winkler's Second Regiment Band. Prayer was offered by the Rev. Dr. W. Strother Jones, rector of St. Michael's Episcopal Church. The United Singing Societies of Trenton, under the direction of Dr. Carl Hoffman, sang "Der Tag Des Herrn." Miss Emily M. Roebling, daughter of Charles G. Roebling, and granddaughter of John A. Roebling, pulled the silken cord which released the United States flags which covered the bronze statue, created by William Couper, of New York. The band then played the bridal chorus from "Lohengrin." Colonel Margerum introduced former Governor Edward Casper Stokes, who, after a brief eulogistic address, introduced Henry D. Estabrook, general counsel of the Western Union Telegraph Company and father of Mrs. Karl G. Roebling, who delivered the oration.

At the close of Mr. Estabrook's address the United Singing Societies sang "The Star-Spangled Banner," which was followed by an address by former state Senator Jonathan H. Blackwell, who introduced the sculptor, William Couper, of New York. The set programme was closed with the rendition of the coronation march from "The Prophet."

During the ceremonies a cablegram from the mayor of Muhlhausen, Germany, the birthplace of Mr. Roebling, was read. A brass wreath sent by the citizens of Muhlhausen was placed on the monument.

The monument is fifteen feet seven inches high, exclusive of the four and one-half feet of concrete base, which is entirely underground. The stonework supporting the statue is nine feet high, and the statue measures six feet seven inches. The figure is modeled in a sitting position. The statue is made of bronze, and was cast in the plant of the Gorham Manufacturing Company, Providence, R. I. The cast was made from a clay model designed by Mr. Couper at his studio in New York city. The pedestal is built entirely of Bonacord red Swedish granite, which was quarried in Sweden and polished in Aberdeen, Scotland. On the right side of the granite pedestal is a bronze panel bearing a reproduction in relief of the first railroad suspension bridge ever built, over the Niagara. On the left side is another panel containing a replica in relief of the Brooklyn Bridge. The front of the pedestal is occupied by the following inscription:

John A. Roebling, Civil Engineer,
Designer and Builder of Many Suspension Bridges,
Founder of Trenton's Greatest Industry,
An Energetic Worker, Inventor and Man of Affairs,
Devoted to His Adopted Country,
In Whose Progress He Had Unswerving Faith:
A Patron of Art and Sciences,
A Benefactor of Mankind.
This Monument Is Erected by the Citizens of Trenton and His Sons in the Year 1907.

The monument in its entirety represents a cost of $14,000, of which $10,000 was expended for the statue. The greater part of this money was obtained by popular subscription, and the remainder was contributed by the sons of the distinguished bridge builder. The committee in charge of the subscription movement follows: Harry S. Maddock, president; Louis Fisher, secretary; Philip Freudenmacher, treasurer; Christian Guenther, Jonathan H. Blackwell, Samuel Walker, John C. Schweizer, General C. Edward Murray and Mahlon R. Margerum.

In connection with the dedicatory ceremonies, former Mayor Daniel J. Bechtel presented handsome souvenir medals of the Roebling monument dedication to Charles G. Roebling, Ferdinand W. Roebling and Colonel Washington A. Roebling. They are made of copper and porcelain, symbolic of two of Trenton's greatest industries.

International Congress of Inventors.

To the Editor of the Electrical Review:

A discussion having arisen in various parts of the country regarding the status of the inventor with relation to the United States Patent Office and expressive of the opinion that inventors of the country should form a national organization for the protection and advancement of their interests, permit us to state that just such an organization exists in the International Congress of Inventors, established in 1906, incorporated in 1907, and having members in several states of the Union, with branches formed or forming in Texas, Missouri, Illinois and California.

This organization was established to benefit inventors as a class by seeking to secure legislation which shall insure to the inventor the services at the Patent Office which his application fees should provide, and the protection for his invention which a government guaranty should give.

Largely through the efforts of the International Congress of Inventors the Federal congress has this year provided for an increased force of examiners in the Patent Office and for an advance in the salaries of Patent Office employés which will tend to retain in government employ those who have become expert in the treatment of applications. A patent fund of $7,000,000 has been accumulated from the sums paid to the government by inventors, and the Patent Office is the only self-sustaining Federal department. Surely the inventors of the country are entitled to the consideration which these facts warrant.

An important matter under consideration by the International Congress of Inventors is the establishment of a standard for a United States patent. The patent system purports to be a method of rewarding inventors and thereby stimulating the production of inventions of value to the public. But patentees and holders of patents find that a United States patent in order to attain a definite standing must be tried out in court. Yet a guaranty of protection issued by the government ought to be something more than a license for a law suit. The International Congress of Inventors is giving this matter careful consideration and it will seek such action by the government as will make a patent conform to its purport. This is one of the many subjects now before this organization. Suggestions in the interest of inventors and all who hold patents are solicited by this organization.

Ralph T. Olcott,
Secretary.

Rochester, N. Y., July 2.

Relation of Government Fuel Investigation to the Solution of the Smoke Problem.

At the annual convention of Smoke Inspectors, held at Cleveland, Ohio, June 24, an address entitled "The Relation of the Government Fuel Investigation to the Solution of the Smoke Problem" was delivered by D. T. Randall, engineer in charge of tests, United States Geological Survey, Fuel Testing Plant. Mr. Randall indicated the great economic waste in the present methods of handling coal as a fuel, and pointed out the savings which were being developed due to the proper utilization of the waste gases in producer plants. He described the work of the Geological Survey, which was begun at St. Louis during the exposition in 1904, and which has since been continued at St. Louis and at Norfolk, Va.

The possible benefits to the government and to the public resulting from such experiments led President Roosevelt to appoint a number of prominent engineers, some in the employ of the government and some members of the great national engineering societies, to act as an advisory board on fuel and structural materials investigations.

A study of the fuel values of coals burned while conducting some 540 boiler tests has shown that the value of the coal depends almost entirely on the number of heat units which it contains. For the coming year a large part of the coal purchased for the government will be paid for according to its heat value as determined in the government chemical laboratories. One of the largest purchases under this form of contract is for use on the Isthmus of Panama, and calls for the delivery of 400,000 tons within the year.

Investigations along other lines have indicated the possibilities of utilizing poorer grades of coal than are now commonly used. Experiments on the briquetting of coal have shown that the slack coal, which is otherwise difficult to utilize, may be made into artificial lumps and used with high efficiency.

Tests upon various furnaces have shown the influence of different methods of burning coal with relation to the reduction of smoke. These tests have pointed to possibilities of modifying furnaces so that practically all fuels may be burned without smoke under favorable conditions.

The fuel-testing department is now at work upon bulletins which deal directly with the smoke problem.

Association of Iron and Steel Electrical Engineers.

The first annual convention of the Association of Iron and Steel Electrical Engineers was held at Philadelphia, Pa., in the rooms of the Engineers' Club, on June 24, 25 and 26. The association has a membership of thirty-three, notwithstanding the fact that only the electrical engineer or the electrical superintendent of the larger iron and steel-producing plants is eligible. Addresses were made by the president, James Farrington, of the La Belle Iron Works, Steubenville, Ohio, and by the secretary, G. H. Winslow, of the National Tube Company, Pittsburg, Pa. During the meeting there were several very interesting discussions on the topics of standardization of mill motors, the Stoeckel induction clutch and drive, electric drilling and reaming, electric motors for heavy torque and rapid reversal, and electric motor drives.

On Thursday, June 25, representatives of manufacturers presented brief discussions concerning apparatus used in connection with mill work. H. D. James, of the Westinghouse Electric and Manufacturing Company, spoke on "Control of Motor-Operated Auxiliary Apparatus for Steel Mills." B. Wiley, of the same company, spoke on "Electrical Equipment of Rolling Mills."

The convention was the guest of the Westinghouse company on Thursday evening at Willow Grove. C. T. Henderson, of the Cutler-Hammer Manufacturing Company, spoke on "New Resistance Grid Interlocking Systems," describing the controlling apparatus installed by this company at Gary, Ind.

On Thursday afternoon the association was entertained at luncheon by Gano S. Dunn, vice-president and chief engineer of the Crocker-Wheeler Company. Later in the afternoon H. F. Stratton, of the Electric Controller and Supply Company, Cleveland, Ohio, described the combination manual and magnetic switch controllers of that company. R. C. Hull, of the Electric Storage Battery Company, spoke on "The Storage Battery in Steel Mills," and on "Storage Battery Regulation of Alternating-Current Circuits." David B. Rushmore, J. G. Callahan, James M. Andrews and K. A. Hawley represented the General Electric Company, and described a number of devices which have recently been brought out by that company.

Trouble for the Mexico City Tramways Company.

The minority stockholders of the Mexico City Tramways Company, Limited, have begun proceedings in the High Court of Justice of England, in London, for an accounting and for the appointment of a receiver for the company. The suit involves property valued at about $10,000,000 in gold.

Current Electrical News

DOMESTIC AND EXPORT.

A $700,000 POWER PLANT PLANNED FOR NEVADA—A movement is on foot to establish at Chalk Mountain, between Wonder and Fairview, Nev., a large power station for the distribution of electricity throughout the mining district. The originators of the plan are P. H. McLaughlin, of Fairview, and Roy Ridge, of Reno, Nev. The electricity will be transmitted a distance of 140 miles to the Chalk Mountain station. The complete plant will cost about $700,000.

PROPOSED SOUTH DAKOTA ELECTRIC ROAD—Articles of incorporation have been filed with the secretary of state for the Aberdeen & Huron Railway Company, with headquarters at Huron, S. D., and a capital of $2,500,000. The company proposes to construct an electric line from Huron to Aberdeen, a distance of eighty miles, to cross the counties of Beadle, Spink and Brown. The incorporators are all Huron men: John A. Cleaver, R. W. Clarke, L. Lapier, J. P. Stahl, G. W. Longstaff, Oscar A. Ricker, R. D. Whorton, R. C. Gibbs and H. J. Rice.

TO BUILD ELECTRIC LINE—The Mesa Valley & El Paso Railway Company, with a capital stock of $1,000,000, has been organized in El Paso, Tex., for the purpose of constructing an electric line between El Paso and Las Cruces, N. M. The incorporators of the concern are El Paso and Las Cruces business men, thirty in all. Each of the thirty has signed for $500 worth of stock in the new company. Papers of incorporation are being drawn up, and it is expected to begin work on the line within thirty days and complete the line within one year. The line will be forty-four miles in length and will traverse some of the richest country in the Rio Grande Valley.

PHILADELPHIA RAPID TRANSIT LOAN—Both branches of the Philadelphia (Pa.) City Councils have approved the plan of the Philadelphia Rapid Transit Company to negotiate a loan of $5,000,000 for extensions and improvements. The conditions of the ordinance provide for the borrowing of $5,000,000, with leaseholds and franchises to be used as pledges. Not more than one-half the total sum is to be raised at the present time, the balance to be secured as needed. New trackage, additional equipment and repairs are the principal uses to be made of the loan money. A number of pay-as-you-enter cars are now being built by the company, and if their use proves successful a part of the money may be used for the purchase of additional cars of this type.

NEW OREGON ELECTRIC RAILWAY ORGANIZED—Articles of incorporation of the Astoria, Seaside & Tillamook Railway Company have been filed in the county clerk's office at Astoria, Ore., by F. L. Evans, E. Z. Ferguson, H. G. Van Dusen and W. E. Buffum, as incorporators. The capital stock is $2,000,000, divided into 200,000 shares of $10 each. The principal office of the company is to be in Astoria, and, according to the articles, its object is to construct and operate an electric railroad and telegraph and telephone lines from Astoria to Tillamook via Warrenton, Hammond and Seaside. It is also authorized to erect and maintain elevators, docks and warehouses and to operate steamers on the Columbia and Willamette rivers, Tillamook Bay and the Pacific Ocean.

MONTANA POWER DEAL—James J. Hill and associates have sold the property of the Great Falls (Mont.) Water Power and Town Site Company to John D. Ryan and others for $1,500,000. John D. Ryan, managing director of the Amalgamated Copper Company, and John G. Marony, president of the Daly Bank and Trust Company of Butte, and of the First National Bank of Great Falls, are the heaviest stockholders. The purchasers deny that the Amalgamated Copper Company has any interest in the deal. The property embraces all of the holdings of the Great Falls Water Power and Town Site Company, a large water-power plant at Black Eagle dam, and the entire generating power of the Missouri River for a distance of twelve miles from the city of Great Falls, east of the "Big" Falls. It is probable that a large electric generating plant will be constructed at the "Big" Falls.

ELECTRIC LIGHTING.

RICHMOND, VA.—The council of Richmond has voted to direct the finance committee to issue bonds not to exceed $350,000 for the purpose of erecting an electric light plant and for improving the city's water system.

PEKIN, ILL.—G. C. Barrett, Milton Seibert and H. G. Herget, managers of the Havana Electric Company, of Pekin, have completed arrangements for the rebuilding of the local plant and the installation of more powerful machinery.

PLYMOUTH, IND.—On Monday, August 10, the city council of Plymouth will receive bids for street lighting for a term of years beginning on the first of February, 1910, according to the proposition on file in the office of the city clerk.

MITCHELL, S. D.—The Mitchell Power Company has bought a block of ground a short distance southeast of the city, upon which it will erect a new electric power-house and a gas plant at a cost of $50,000. Mitchell men are behind the enterprise.

LOGANSPORT, IND.—The board of public works has contracted with Professor Walter Esterline, of Purdue University, to supervise the purchase and putting in of the machinery for the electric light plant, for which the City Council has appropriated $30,000.

OKEMAH, OKLA.—At a mass meeting Okemah citizens approved the plan of voting bonds for the improvement of streets and the installation of a water and electric light plant. For the first proposition $7,000 will be required, and for the latter $8,000.

FORT SCOTT, KAN.—Superintendent F. D. Martin, of the Fort Scott Gas and Electric Company, states that his company is preparing to spend the sum of $50,000 to improve its plant and equipment at this point. It is expected that the work will begin some time this summer or early in the fall.

SALTILLO, MEX.—The new electric light and power plant of this city will be ready, it is stated, in August next. The plant will be a model in every respect and fitted up with new machinery, recently imported from Germany. The machinery represents an expenditure of $150,000, the company being capitalized at $200,000.

NORFOLK, VA.—In the Federal Court an order signed by Judge Waddill has been recorded authorizing the receivers of the Public Service Corporation of Virginia, at Hampton, to contract with the town officials of Phœbus to furnish twenty-one lights at a price of $30 per annum each. The contract will be for two years, subject to renewal for three years additional at the same price.

WASHINGTON, D. C.—The Potomac Electric Power Company has sold to Brown Brothers & Company, of New York, $650,000 consolidated mortgage 5 per cent bonds. The authorized amount of this issue is $7,000,000, of which $2,700,000 is now outstanding, $1,700,000 is held to retire a like amount of first mortgage bonds due in June, 1921, and the remainder, $2,600,000, is in the treasury of the company to be issued from time to time to pay for extension, betterments and improvements.

CHICAGO, ILL.—The Commonwealth Edison Company will make a general reduction in its rates for electricity August 1. The company has shown a large increase in business since the first of the year. Its contracts with the street-car companies, while the largest individual transactions, are not larger in the aggregate than the volume of smaller ones that have been obtained in the last six months. The company has more ready money on hand than at any previous time. No fresh funds will be required for new construction or further improvements this year. Sometime early in 1909, however, new securities probably will be sold. These will undoubtedly be the five per cent general mortgage bonds of the Commonwealth Electric Company. At the same time it is likely that the directors may arrange a new mortgage, and all of the underlying bonds will be refunded.

PERSONAL MENTION.

MR. ABNER COLEMAN has been reappointed manager of the municipal electric light plant of Taunton, Mass., for a period of three years from July 1. Mr. Coleman has held this position since 1891.

MR. FRANK HEDLEY, general manager of the Interborough Rapid Transit Company, has been elected a vice-president of the company. His title hereafter will be vice-president and general manager.

MR. GEORGE LORING, who has been connected for some time with the engineering department of the National Electric Association, became identified, on July 1, with the sales department of the Shelby Electric Company, of Shelby, Ohio. Mr. Loring was connected with this company in various sales capacities for eight years previous to going with the National Electric Lamp Association. Mr. Loring will devote a great deal of his time to pushing tungsten lamp sales, as the Shelby Company will be very active in the production of this type of incandescent lamp. For several years Mr. Loring has been a prominent figure at state and national electrical conventions and has contributed a number of important papers on the subject of incandescent lamps and illumination. His extensive experience, wide acquaintance and demonstrated ability make him a strong factor in the Shelby sales organization.

MR. LOUIS A. FERGUSON, who now takes up the duties of president of the American Institute of Electrical Engineers, was born in Dorchester, Mass., August 19, 1867. He was educated in the Boston public schools and graduated from the Dorchester High School in 1884. Entering the Massachusetts Institute of Technology he graduated in 1888 with the degree of bachelor of science in the electrical engineering department. Shortly after his graduation he began his association with the Chicago Edison Company in the underground department. In 1889 he was made assistant electrical engineer of the construction department, and in 1890 was appointed electrical engineer. So successful was his work in the engineering and operating departments, and so excellent his carrying out of those problems which involved commercial considerations, that in 1893 his duties were enlarged to cover the entire supervision of the company's contract business, in addition to his engineering work. In this field he was particularly successful, negotiating a number of valuable long-term contracts with some of the largest mercantile institutions in Chicago. On June 1, 1897, he was appointed general superintendent of the company, in charge of operating and electrical engineering departments as well as the central station and isolated-plant business. A year later he was appointed general superintendent of the Commonwealth Electric Company. On July 9, 1902, the directors of the Chicago Edison Company and of the Commonwealth Electric Company elected him second vice-president of both companies. This position he holds at the present time. He was elected president of the Association of Edison Illuminating Companies for the year 1901-1902, and re-elected to the same position for the year 1902-1903. He was elected president of the National Electric Light Association for the year 1902-1903, and he is now a member of the executive committees of both associations. Mr. Ferguson is credited with being the first engineer in this country to recommend a central station system generating three-phase alternating current with transmission lines to substations operating rotaries converting from alternating to direct current for general distribution. He has been prominently before the American Institute of Electrical Engineers, the Association of Edison Illuminating Companies and the National Electric Light Association as an exponent of the most progressive ideas in electrical development. His literary contributions form some of the most classical reading which is available in the electrical field. He is a member of the Commercial Club of Chicago, the University Club, the Union League Club, Chicago Athletic Club, Mid-Day Club, Evanston Country Club, and the Onwentsia and Glen View Golf clubs. He has always been interested in public-spirited work in Chicago, and, in connection with this, served three years on the executive committee of the Merchants' Club.

MR. LOUIS A. FERGUSON.

ELECTRICAL SECURITIES.

So far as the stock market is concerned, there is little to chronicle of the doings of the short week ended Friday, July 3. The apathy which set in several weeks ago continued with the dulness intensified. Notwithstanding this, the indications still hold good that each day brings a brightening prospect. Idle freight cars are decreasing, and reports come in of new life in repair shops and rolling mills. The crop outlook is very encouraging, and labor more efficient than for many a day. It appears that there are few large accumulations of commodities to be disposed of, and that of necessity the recovery will be rapid and well sustained.

Dividends have been declared upon the following electrical securities: National Light, Heat and Power Company, regular quarterly dividend of 1¼ per cent on the preferred stock, payable July 1. Manchester Traction, Light and Power Company; regular quarterly dividend of 2 per cent, payable July 15 to stock of record July 1. Scranton Electric Company; quarterly dividend of 1½ per cent on the preferred stock, payable July 1. Philadelphia City Passenger Company; a semi-annual dividend of $3.75 per share, payable July 10 to stock of record June 29. Butte Electric and Power Company; a dividend of 1½ per cent on the common stock, payable July 6 to stock of record June 30. The common dividend was passed last December, previous to which time the rate was 1¼ per cent. The directors of the Electric Company of America have declared the regular semi-annual dividend of 3½ per cent to stock of record July 10. Books close July 10 and reopen August 4.

ELECTRICAL SECURITIES FOR THE WEEK ENDED JULY 4.

New York:	*Closing.*
Allis-Chalmers common	11½
Allis-Chalmers preferred	35½
Brooklyn Rapid Transit	48
Consolidated Gas	125½
General Electric	—
Interborough-Metropolitan common	11¾
Interborough-Metropolitan preferred	30⅝
Kings County Electric	115
Mackay Companies (Postal Telegraph and Cables) common	64
Mackay Companies (Postal Telegraph and Cables) preferred	64¼
Manhattan Elevated	134
Metropolitan Street Railway	23
New York & New Jersey Telephone	100
Western Union	55
Westinghouse Manufacturing Company	53¾

Boston:	*Closing.*
American Telephone and Telegraph	115
Edison Electric Illuminating	208
Massachusetts Electric	46½

Philadelphia:	*Closing.*
Electric Company of America	10½
Electric Storage Battery common	30
Electric Storage Battery preferred	30
Philadelphia Electric	9¼
Philadelphia Rapid Transit	17⅛
United Gas Improvement	85¼

It is estimated that the gross earnings of the Philadelphia Rapid Transit Company, in the fiscal year ended June 30, 1908, were $18,400,000, an increase of about $300,000.

Chicago.	*Closing.*
Chicago Telephone	135
Commonwealth Edison	100¼
Metropolitan Elevated preferred	49¾
National Carbon common	69
National Carbon preferred	111

The daily average number of passengers carried on the elevated railroads during June was as follows: Metropolitan Elevated, 144,361; decrease, 4,167. South Side Elevated, 125,876; increase, 10,190. Northwestern Elevated, 109,107; increase, 10,056.

OBITUARY NOTE.

MR. GEORGE H. DANIELS, for many years prominently identified with the New York Central & Hudson River Railroad, died at Lake Placid, N. Y., on July 1. Mr. Daniels had been ill for some time, and his death was expected for several days. He was suffering from hardening of the arteries, with other complications. Mr. Daniels was born on a farm at Hampshire, Ill., in 1842. Like many other railroad men, he began at the foot of the ladder, starting in at the age of fifteen as a rodman in the engineering corps of the North Missouri Railroad. His advance was rapid, and in 1872 he was made general freight and passenger agent of the Chicago & Pacific Railroad. He served in various offices, notably as commissioner of the Central Traffic Association, and in 1889 was made general passenger agent of the New York Central & Hudson River Railroad. He became conspicuous in this position for his advertising ability, the name "Empire State Express" being one of his inventions. It is said that during Mr. Daniels' service as general passenger agent the New York Central lines were the best and most widely advertised in the world. In 1905 Mr. Daniels was appointed international advertising manager of the New York Central lines, serving in that office until his retirement. The death of Mr. Daniels comes as a personal loss to a host of men prominent in every walk of life. No one could come in contact with him without being impressed with his great personality, and the regard in which he was held amounted in many instances to the sincerest affection. Not only did he endear himself to many, but he served the country in a noteworthy manner. The Adirondacks, the Hudson River, the Thousand Islands, Niagara Falls and other beauty spots of the United States became familiar points of interest and were impressed upon the public mind in such indelible fashion through his efforts that it might truly be said that, having done his work so well, the necessity does not remain for any one to take his place.

MR. GEORGE H. DANIELS.

NEW INCORPORATIONS.

COLUMBUS, OHIO—Cadiz Electric Company, Cadiz. Capital stock increased from $12,000 to $60,000.

SALEM, ORE.—Mollalla Power Company, Canby. $10,000. Incorporators: John B. Hurst, W. S. Hurst and Fred P. Hurst.

AUSTIN, TEX.—Cisco Light and Power Company, of Cisco. $16,000. Incorporators: G. W. Troxwell, W. C. Bedford and C. H. Free.

AUSTIN, TEX.—Luzon Telephone Company, of Clairemont, Kent County. $25,000. Incorporators: S. A. McCombs, T. G. Harkey and J. M. Kelley.

RALEIGH, N. C.—Suburban Land and Power Company. To operate railways and electric power plants, distribute electricity and gas, and engage in other business. $40,000. Incorporators: E. J. Parrish, J. M. Gregory, John Sprunt Hill, W. W. White, R. W. Winston.

SALT LAKE CITY, UTAH.—Electric Supply and Fixture Company. $20,000. Officers and directors: R. W. Nichol, president; A. T. Wright, vice-president; D. C. Eccles, treasurer; C. J. Humphris, secretary; A. E. Lawrence, director. To generate electricity and establish electric distributing systems.

JERSEY CITY, N. J.—Charlotte Power Company. Formed to manufacture and operate street and railway cars, evidently in Charlotte, N. C. $300,000 in $100 shares. Incorporators: Oscar L. Wold, Wade M. Adams and T. C. Raine. Southern Construction Company, allied with the above with $100,000 in $100 shares.

ELECTRIC RAILWAYS.

DANVILLE, PA.—The Sunbury & Selinsgrove Electric Railway has been completed and placed in operation.

DAYTON, OHIO—The Circuit Court has upheld the validity of the fifty-year franchise of the Oakwood Street Railway Company, which had been attacked by the municipality.

STEUBENVILLE, OHIO—The new $7,000,000 Ohio River Passenger Electric Railway Company's "Ohio River Scenic Route" from Vanport to Steubenville, Ohio, was thrown open to the public on June 28.

GRAND JUNCTION, COL.—The city council has granted to H. E. Devereaux, of Colorado Springs, a franchise to build a street railway in Grand Junction. Work will begin July 15 and cars must be operated on three miles of track within one year.

KANSAS CITY, MO.—The contract for the Oregon interurban railway to be built from the Burlington tracks to Oregon, Mo., has been let. The contract calls for the road to be completed with all equipments, switches and bridges, less terminal and rolling stock, within 100 days.

BISMARCK, MO.—A party of St. Louis capitalists and the Business Men's Club of Irondale have completed the preliminary arrangements for an electric railroad to extend from Belgrade, in Washington County, to Perryville, in Perry County. A dam across Big River, near Irondale, will furnish the motive power.

McKINNEY, TEX.—At a meeting of the citizens of this place, Bonham, Blue Ridge and other points, W. S. Cole, of Detroit, Mich., representing Eastern capitalists, presented a proposition for the construction of an electric railway between Fort Worth and Bonham. The proposition was accepted and an organization of the stockholders effected, with J. L. Lovejoy as chairman.

UTICA, N. Y.—The Public Service Commission has authorized the Dolgeville & Salisbury Railway Company to increase its capital stock from $100,000 to $150,000 and to issue $150,000 common capital stock. The capital stock is to be issued at not less than the par value, the proceeds to be used for building the railway between Dolgeville and the Salisbury Steel and Iron Company's plant, a distance of about four miles.

BUFFALO, N. Y.—E. H. Rogers, a wealthy Tonawanda contractor, and a number of other capitalists are understood to be organizing a company to build an eight-mile trolley line over private right of way from O'Neill street down the river front to Tonawanda, passing close to the new Wickwire Steel Plant and being partially designed to give transportation facilities to and from that plant, which is to employ upward of 500 men.

MANSFIELD, OHIO—The stockholders of the Mansfield Street Railway, Light and Power Company at their annual meeting elected the following board of directors: S. N. Ford, Mansfield; F. E. Myers, Ashland; J. A. Rutherford, F. L. Fuller and E. F. Snyder, Cleveland; T. H. Creden, Chicago; Charles W. Dupuis, Cincinnati. The board organized by electing S. N. Ford, of Mansfield, president; F. L. Fuller, of Cleveland, vice-president, and Sidney A. Foltz, of Mansfield, secretary and treasurer. Mr. Foltz was also chosen manager.

ROCHESTER, N. Y.—The Rochester, Scottsville & Caledonia Electric Railway Company, which was incorporated to build a line from Rochester to Caledonia, has decided to branch out in several directions as well as carrying the line on through to Portage, a distance of fifty-five miles, following the Genesee Valley and skirting the shores of Silver Lake. The line will cross the river between West Henrietta and Scottsville, thence will run southwesterly to Garbutt, Wheatland, Mumford and the State Fish Hatchery, thence to Caledonia, to the salt mines of Retsof and Greigsville, touching at Le Roy and passing through the Oatka Valley to Pavilion; then across Pear Creek, through La Grange and Perry Center to Perry, Silver Lake, Castile and Portage. The president of the company is David C. Salyerds, and the local incorporators are Henry C. Brewster, George C. Buell, Charles P. Ford, Charles T. Chapin, Andrew H. Brown, Isaac W. Salyerds and Edmund Lyon. The line will be known as the Scenic Route. The total cost of its construction from Rochester to Portage is estimated at $2,135,000.

TELEPHONE AND TELEGRAPH.

MARSHALL, MICH.—Improvements costing about $1,000 have been made to the local exchange of the Citizens' Telephone Company.

READING, PA.—The American Union Telephone Company has increased to a considerable extent its trunk line facilities in this section of the state.

WILMINGTON, DEL.—The Delaware & Atlantic Telegraph and Telephone Company will remove all poles within the city where possible and place its wires underground.

JOPLIN, MO.—Work has been begun on the foundation for the new Bell Telephone building, which is estimated to cost $250,000. It will be forty-six by seventy-five feet in area and three stories in height, and is expected to be completed in October.

STEPHENS, ARK.—A new telephone company composed of local citizens has been organized here and application has been made to the city council for a franchise. There are nearly 200 members of the new company and they propose to begin work early in July.

SAN MARCIAL, N. M.—T. J. Mathews is authority for the statement that the Socorro County Telephone Company, of which he is manager, will extend its system as far as the Elephant Butte dam this year, and as soon as possible connections will be made to El Paso.

NEW YORK, N. Y.—The New York & New Jersey Telephone Company announces a change of rate affecting telephone subscribers in the Coney Island, Bath Beach, Astoria and Long Island City sections. Brooklyn Borough, Astoria and Long Island City, in the Borough of Queens, are considered one local service area. The company also announces that rates for messages from public telephones in Bath Beach and Coney Island are reduced to five cents to Brooklyn, and ten cents, instead of fifteen cents, to Manhattan. The change is in effect.

INDUSTRIAL ITEMS.

THE LINCOLN MOTOR WORKS COMPANY, Caxton Building, Cleveland, Ohio, has ready for distribution a new bulletin devoted to type A Lincoln variable-speed motors.

THE NORTON COMPANY, Worcester, Mass., has published a very interesting booklet giving a great deal of information concerning the use of grinding and abrading wheels.

THE BRISTOL COMPANY, Waterbury, Ct., has issued bulletin No. 92, devoted to Bristol's recording thermometer, Class II, for temperatures between forty degrees and 500 degrees Fahrenheit.

THE NORTHERN ELECTRICAL MANUFACTURING COMPANY, Madison, Wis., will be pleased to send to any one interested upon request, a new bulletin descriptive of type B direct-current motors and generators.

THE AMERICAN STEEL AND WIRE COMPANY, The Rookery, Chicago, Ill., has published a great deal of information of value and interest concerning steel wires and ropes in the "American Wire Rope News" for May.

THE HOLTZER-CABOT ELECTRIC COMPANY, Brookline, Boston, Mass., has ready for distribution bulletins Nos. 307B, 314A and 316, descriptive, respectively, of buffing and grinding motors for direct and alternating current, type "C" motors and dynamos for direct current, and type "LM" motors for direct current.

THE FOSTORIA GLASS SPECIALTY COMPANY, Fostoria, Ohio, his issued a blotter enclosed in a folder representing a giant firecracker. In connection with the July holiday spirit the company states that the central station manager can announce a declaration of independence and celebrate this day of days by declaring for "Noblac" inner globes.

THE TRUMBULL ELECTRIC MANUFACTURING COMPANY, Plainville, Ct., in the July issue of "Trumbull Cheer" calls attention to its type C switches. These are made with and without fuses in all capacities for 250 and 500 volts. A supplement to this issue of "Trumbull Cheer" shows a sixty-foot switchboard made up of thirty panels, built by the Trumbull Electric Manufacturing Company.

THE WARD LEONARD ELECTRIC COMPANY, Bronxville, N. Y., has issued a new catalogue, No. H1a, devoted to battery charging rheostats for electric automobiles, for private plants and garage duty; also rheostats to take care of the discharge of storage cells. and a complete line of charging rheostats for ignition cells and portable batteries. Copies of the catalogue will be furnished to those interested upon request.

W. N. MATTHEWS & BROTHER, 227 North Sixth street, St. Louis, Mo., are the exclusive sales agents of an improved form of incandescent lamp changer. By means of this apparatus the operator can replace incandescent lamps in lofty or almost inaccessible places. The company suggests the advantage of central station companies making use of this lamp changer in facilitating the replacing of burned-out lamps by their customers.

THE GENERAL ELECTRIC COMPANY, Schenectady, N. Y., has issued a comprehensive bulletin, No. 4,593, devoted to the subject of "Railway Converter Substations." This publication gives a general description of the various pieces of substation apparatus and includes illustrations of converter stations operated by well-known railway companies. Another bulletin, No. 4,590, is devoted to automatic compensating devices for alternating-current motors.

THE PRATT & WHITNEY COMPANY, Hartford, Ct., has issued a handsome catalogue devoted to the Spline milling machine. This is an absolutely new tool embodying new principles and taking care of work for which heretofore there has been no suitable machinery. By its use the designer is enabled to take advantage of the use of slots, which many times simplify the design, but which, heretofore, have been avoided owing to the high manufacturing cost. The aim in bringing out the new tool has been to produce a machine specially built for slot milling, particularly slots with closed ends.

THE F. BISSELL COMPANY, 226-230 Huron street, Toledo, Ohio, has ready for distribution a list of second-hand machinery. This is entitled "The Little Book of Real Bargains." While this department of the Bissell Company's business has been in existence for a good many years, it was not until the last year that it entered into the second-hand machinery business on a large scale. A good deal of the success of this department can be attributed to the fact that the company buys or trades as well as sells apparatus. The Bissell Company will be pleased to place the name of any one interested on its mailing list for this booklet of bargains.

THE CENTRAL ELECTRIC COMPANY, Chicago, Ill., is distributing new catalogues on malleable-iron specialties, such as anchors, feeder arms, pins, cross-arms, bolts, wall brackets, spreader brackets, strain plates, strain insulators, corner brackets, catenary hangers, etc. The catalogue includes the report of tests made by Columbia University, New York city, on the malleable-iron cross-arm bolt, these tests being made to ascertain the load required to strip or destroy the bolt threads. The catalogue contains about forty pages, and will be found of interest to consulting engineers and station managers. Copies will be furnished upon request.

THE CUTLER-HAMMER MANUFACTURING COMPANY, Milwaukee, Wis., makers of electric controlling devices, has completed arrangements whereby it will be represented on the Pacific Coast by Otis & Squires, of 111 New Montgomery street, San Francisco, Cal. A large stock of standard Cutler-Hammer controllers will be carried by Otis & Squires, enabling them to make prompt delivery of apparatus. A. W. Vinson, who has for several years been connected with the engineering department of the Cutler-Hammer Manufacturing Company, has been transferred to the office of Otis & Squires, where his services will be available to those confronted with problems of electrical control which can not be met by the use of standard apparatus.

W. R. BRIXEY, manufacturer of the well-known "Kerite" wires and cables, has moved to larger and more commodious offices on the nineteenth floor of the Cortlandt Building of the Hudson Terminal, 30 Church street, New York city. Probably no pleasanter offices in this line are to be found in the city, as they overlook the Hudson River and are airy and large. R. D. Brixey, son of W. R. Brixey, is in charge of the affairs of the company. A large branch office has been established in the Railway Exchange Building, Chicago, Ill., under the direction of the company's representative, the Watson Insulated Wire Company. One of the conspicuous features of the New York office is a large and very perfect rubber biscuit, said to be the finest ever imported to this country, which came from Brazil, and is on exhibition in the ante-room, containing probably $1,000 worth of pure Para rubber.

Directory of Electrical and Allied Engineering and Scientific Societies.

(Published in the Second Issue of Each Month.)

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE. Secretary, L. O. Howard, Cosmos Club, Washington, D. C.

AMERICAN ELECTROTHERAPEUTIC ASSOCIATION. Secretary, Dr. Albert C. Geyser, 352 Willis avenue, New York city.

AMERICAN ELECTROCHEMICAL SOCIETY. Secretary, Dr. J. W. Richards, Bethlehem, Pa. Fall meeting, New York city, October 30-31.

AMERICAN FOUNDRYMEN'S ASSOCIATION. Secretary, Dr. Richard Moldenke, Watchung, N. J.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS. Secretary, Ralph W. Pope, Engineering Societies Building, 29 West Thirty-ninth street, New York City. Meetings, second Friday of each month.

AMERICAN MATHEMATICAL SOCIETY. Secretary, F. N. Cole, 50 West 116th street, New York city.

AMERICAN RAILWAY MASTER MECHANICS' ASSOCIATION. Secretary, J. W. Taylor, Old Colony Building, Chicago, Ill.

AMERICAN ROENTGEN RAY SOCIETY. Secretary, Dr. G. C. Johnson, 514 Bijou Building, Pittsburg, Pa.

AMERICAN SOCIETY FOR TESTING MATERIALS. Secretary, Professor Edgar Marburg, University of Pennsylvania, Philadelphia, Pa.

AMERICAN SOCIETY OF CIVIL ENGINEERS. Secretary, Charles Warren Hunt, 220 West Fifty-seventh street, New York city.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS. Secretary, Calvin W. Rice, 29 West Thirty-ninth street, New York city.

AMERICAN SOCIETY OF MUNICIPAL IMPROVEMENTS. Secretary, G. W. Tillson, Park Row Building, New York city. Annual meeting, Atlantic City, N. J., October.

AMERICAN STREET AND INTERURBAN RAILWAY ASSOCIATION. Secretary, B. V. Swenson, Engineering Societies Building, 29 West Thirty-ninth street, New York city. Annual convention, Atlantic City, N. J., October 12-16.

AMERICAN STREET AND INTERURBAN RAILWAY ACCOUNTANTS' ASSOCIATION. Secretary, Elmer M. White, treasurer Birmingham Railway, Light and Power Company, Birmingham, Ala. Annual convention, Atlantic City, N. J., October 12-16.

AMERICAN STREET AND INTERURBAN RAILWAY CLAIM AGENTS' ASSOCIATION. Secretary, B. B. Davis, claim agent Columbus Railway and Light Company, Columbus, Ohio. Annual convention, Atlantic City, N. J., October 12-16.

AMERICAN STREET AND INTERURBAN RAILWAY ENGINEERING ASSOCIATION. Secretary, J. W. Corning, electrical engineer Boston Elevated Railway Company, Boston, Mass. Annual convention, Atlantic City, N. J., October 12-16.

AMERICAN STREET AND INTERURBAN RAILWAY MANUFACTURERS' ASSOCIATION. Secretary, George B. Keegan, 2321 Park Row Building, New York city. Annual convention, Atlantic City, N. J., October 12-16.

ARKANSAS INDEPENDENT TELEPHONE ASSOCIATION. Secretary, Charles F. Speed, Texarkana, Ark.

ASSOCIATION OF EDISON ILLUMINATING COMPANIES. Secretary, W. W. Freeman, vice-president and general manager Edison Electric Illuminating Company, Brooklyn, N. Y.

ASSOCIATION OF ELECTRIC LIGHTING ENGINEERS OF NEW ENGLAND. Secretary, Welles E. Holmes, 308 Washington street, Newton, Mass.

ASSOCIATION OF RAILWAY TELEGRAPH SUPERINTENDENTS. Secretary, P. W. Drew, Wisconsin Central Railway, Milwaukee, Wis.

CALIFORNIA ELECTRIC RAILWAY ASSOCIATION. Secretary, L. E. W. Pioda, Oak and Broderick streets, San Francisco, Cal.

CALIFORNIA INDEPENDENT TELEPHONE ASSOCIATION. Secretary, P. T. Whittier, Spencer, Cal.

CANADIAN ELECTRICAL ASSOCIATION. Secretary, T. S. Young, Toronto, Canada.

CANADIAN STREET RAILWAY ASSOCIATION. Secretary, Acton Burrows, 33 Melinda street, Toronto, Ontario.

CENTRAL ELECTRIC RAILWAY ASSOCIATION. Secretary, W. F. Milholland, secretary and treasurer Indianapolis Traction and Terminal Company, Indianapolis, Ind.

COLORADO ELECTRIC LIGHT, POWER AND RAILWAY ASSOCIATION. Secretary, J. F. Dostal, Denver, Col. Annual convention, Glenwood Springs, Col., September 16-18.

CONNECTICUT STATE STREET RAILWAY ASSOCIATION. Secretary, F. W. Poole, Bridgeport, Ct.

ELECTRIC CLUB OF CLEVELAND. Secretary, George L. Crosby, 1200 Schofield Building, Cleveland, Ohio.

ELECTRICAL CONTRACTORS' ASSOCIATION OF NEW YORK STATE. Secretary, John P. Faure, 77 Water street, Ossining, N. Y.

ELECTRICAL CONTRACTORS' ASSOCIATION OF STATE OF MISSOURI. Secretary, Charles J. Sutter, 1220 Pine street, St. Louis, Mo.

ELECTRICAL TRADES ASSOCIATION OF CHICAGO. Secretary, Frederic P. Vose, Marquette Building, Chicago.

ELECTRICAL TRADES ASSOCIATION OF PHILADELPHIA. Secretary, E. A. Symmes, 810 Drexel Building, Philadelphia, Pa. Meetings, second and fourth Thursdays of each month.

ELECTRICAL TRADES ASSOCIATION OF CANADA, LIMITED. Secretary, William R. Stanley, Royal Insurance Building, Montreal, Canada.

ELECTRICAL TRADES ASSOCIATION OF THE PACIFIC COAST. Secretary, Albert H. Elliott, Claus Spreckels Building, San Francisco, Cal. Monthly meetings, San Francisco, first Thursday of each month.

ELECTRICAL TRADES SOCIETY OF NEW YORK (Member National Electrical Trades Association). Secretary, Franz Neilson, 80 Wall street, New York city. Board of directors meets second Friday of each month.

EMPIRE STATE GAS AND ELECTRIC ASSOCIATION. Secretary, Charles H. B. Chapin, 154 Nassau street, New York city.

ENGINEERS' CLUB OF PHILADELPHIA. Secretary, H. G. Perring, 1317 Spruce street, Philadelphia, Pa.

ENGINE BUILDERS' ASSOCIATION OF THE UNITED STATES. Secretary, J. I. Lyle, 39 Cortlandt street, New York city.

ILLINOIS INDEPENDENT TELEPHONE ASSOCIATION. Secretary, C. A. Camp, Henry, Ill.

ILLINOIS STATE ELECTRICAL ASSOCIATION. Secretary, H. E. Chubbuck, La Salle, Ill.

ILLUMINATING ENGINEERING SOCIETY. Secretary, Van Rensselaer Lansingh, Engineering Societies Building, 33 West Thirty-ninth street, New York city. Annual convention, Philadelphia, Pa., October 6-7.

INDEPENDENT TELEPHONE ASSOCIATION OF TEXAS AND LOUISIANA. Secretary, C. A. Shock, Sherman, Tex.

INDIANA ELECTRIC RAILWAY ASSOCIATION. Secretary, P. H. White, Indianapolis, Ind. Monthly meetings, second Tuesday of each month.

INDIANA INDEPENDENT TELEPHONE ASSOCIATION. Secretary, C. S. Norton, Indianapolis, Ind.

INTERNATIONAL ASSOCIATION OF MUNICIPAL ELECTRICIANS. Secretary, Frank P. Foster, Corning, N. Y. Annual meeting, Detroit, Mich., August 19-21.

INTERNATIONAL INDEPENDENT TELEPHONE ASSOCIATION. Secretary, J. B. Ward, Grand Rapids, Mich.; assistant secretary, J. A. Harney, Monadnock Building, Chicago, Ill.

IOWA ELECTRICAL ASSOCIATION. Secretary, W. N. Keiser, Des Moines, Iowa.

IOWA INDEPENDENT TELEPHONE ASSOCIATION. Secretary C. C. Deering, Boone, Iowa.

IOWA STREET AND INTERURBAN RAILWAY ASSOCIATION. Secretary, L. D. Mathes, Dubuque, Iowa.

KANSAS GAS, WATER, ELECTRIC LIGHT AND STREET RAILWAY ASSOCIATION. Secretary, James D. Nicholson, Newton, Kan.

KENTUCKY INDEPENDENT TELEPHONE ASSOCIATION. Secretary, W. G. Turpine, Henderson, Ky.

MAINE INDEPENDENT TELEPHONE ASSOCIATION. Secretary, M. E. Crow, Houlton, Me.

MAINE STREET RAILWAY ASSOCIATION. Secretary, E. A. Newman, 471 Congress street, Portland, Me.

MASSACHUSETTS STREET RAILWAY ASSOCIATION. Secretary, Charles S. Clark, 70 Kilby street, Boston, Mass. Meets second Wednesday of each month, except July and August.

MASTER CAR BUILDERS' ASSOCIATION. Secretary, J. W. Taylor, 390 Old Colony Building, Chicago, Ill.

MICHIGAN ELECTRIC ASSOCIATION. Secretary, A. C. Marshal, Port Huron, Mich. Annual meeting, Grand Rapids, Mich., August 18-21.

MICHIGAN INDEPENDENT TELEPHONE ASSOCIATION. Secretary, A. A. Burch, Battle Creek, Mich.

MISSOURI ELECTRIC LIGHT, GAS AND STREET RAILWAY ASSOCIATION. Secretary, Claude L. Clary, Sikeston Electric Light and Power Company, Sikeston, Mo.

MISSOURI INDEPENDENT TELEPHONE ASSOCIATION. Secretary, George W. Schweer, Windsor, Mo.

NATIONAL ARM, PIN AND BRACKET ASSOCIATION. Secretary, J. B. Magers, Madison, Ind.

NATIONAL ELECTRICAL CONTRACTORS' ASSOCIATION OF THE UNITED STATES. Secretary, W. H. Morton, 94 Genesee street, Utica, N. Y. Next meeting, Chicago, Ill., July 15-17.

NATIONAL ELECTRICAL TRADES ASSOCIATION. Secretary, Frederic P. Vose, 1343 Marquette Building, Chicago.

NATIONAL ELECTRIC LIGHT ASSOCIATION. Secretary, John F. Gilchrist, Commonwealth Edison Company, Chicago, Ill.

NEBRASKA ELECTRICAL ASSOCIATION. Secretary, William Bradford, Lincoln.

NEBRASKA INDEPENDENT TELEPHONE ASSOCIATION. Secretary, R. E. Mattison, Lincoln, Neb.

NEW ENGLAND ELECTRICAL TRADES ASSOCIATION. Secretary, Alton F. Tupper, 60 State street, Boston, Mass.

NEW ENGLAND STREET RAILWAY CLUB. Secretary, John J. Lane, 12 Pearl street, Boston, Mass. Meetings held on fourth Thursday of every month.

NEW YORK ELECTRICAL SOCIETY. Secretary, G. H. Guy, Engineering Societies Building, 29 West Thirty-ninth street, New York city.

NEW YORK STATE INDEPENDENT TELEPHONE ASSOCIATION. Secretary, R. Max Eaton, Niagara Falls, N. Y.

NORTHWESTERN ELECTRICAL ASSOCIATION. Secretary, R. N. Kimball, Kenosha, Wis.

OHIO ELECTRIC LIGHT ASSOCIATION. Secretary, D. L. Gaskill, Greenville, Ohio. Annual convention, Put-in-Bay, Ohio, August 25-27.

OHIO INDEPENDENT TELEPHONE ASSOCIATION. Secretary, O. O. Welsheimer, Columbus, Ohio.

OHIO SOCIETY OF MECHANICAL, ELECTRICAL AND STEAM ENGINEERS. Secretary, F. W. Ballard, Cleveland, Ohio.

OHIO STREET RAILWAY ASSOCIATION. Secretary, Charles Currie, Akron, Ohio.

OKLAHOMA ELECTRIC LIGHT, RAILWAY AND GAS ASSOCIATION. Secretary, Galen Crow, Guthrie, Okla.

OLD TIME TELEGRAPHERS' AND HISTORICAL ASSOCIATION. Secretary, John Brant, 195 Broadway, New York city.

ORDER OF THE REJUVENATED SONS OF JOVE. C. B. Roulet, Mercury, Dallas, Tex.

PACIFIC COAST ELECTRIC TRANSMISSION ASSOCIATION. Secretary, Samuel G. Reed, Portland, Ore.

PENNSYLVANIA STATE INDEPENDENT TELEPHONE ASSOCIATION. Secretary, H. E. Bradley, 135 South Second street, Philadelphia.

PENNSYLVANIA STATE STREET RAILWAY ASSOCIATION. Secretary, Charles H. Smith, Lebanon, Pa.

PIKES PEAK POLYTECHNIC SOCIETY. Secretary, E. A. Sawyer, Colorado Springs, Col. Meetings, second Saturday of each month.

RAILWAY SIGNAL ASSOCIATION. Secretary, C. C. Rosenberg, Bethlehem, Pa.

SOCIETY FOR THE PROMOTION OF ENGINEERING EDUCATION. Secretary, Arthur L. Williston, Pratt Institute, Brooklyn, N. Y.

SOUTH DAKOTA INDEPENDENT TELEPHONE ASSOCIATION. Secretary-treasurer, E. R. Buck, Hudson, S. D.

SOUTHWESTERN ELECTRICAL AND GAS ASSOCIATION. Secretary, J. A. Myler.

STREET RAILWAY ASSOCIATION OF THE STATE OF NEW YORK. Secretary, J. H. Pardee, J. G. White & Company, New York, N. Y.

TEXAS INDEPENDENT TELEPHONE ASSOCIATION. Secretary, Charles F. Speed, Texarkana, Tex.

UNDERWRITERS' NATIONAL ELECTRIC ASSOCIATION. Secretary Electrical Committee, C. M. Goddard, 55 Kilby street, Boston, Mass.

VERMONT AND NEW HAMPSHIRE INDEPENDENT TELEPHONE ASSOCIATION. Secretary-treasurer, G. W. Buzzell, St. Johnsbury, Vt.

VERMONT ELECTRICAL ASSOCIATION. Secretary, C. C. Wells, Middlebury Electric Light Company, Middlebury, Vt.

VIRGINIA STATE INDEPENDENT TELEPHONE ASSOCIATION. Secretary, B. L. Fisher, Rocky Mount, Va.

WESTERN ASSOCIATION OF ELECTRICAL INSPECTORS. Secretary, W S. Boyd, 382 Ohio street, Chicago, Ill.

WESTERN SOCIETY OF ENGINEERS (Electrical Section). Secretary, J. H. Warder, 1737 Monadnock Block, Chicago, Ill.

WISCONSIN ELECTRIC AND INTERURBAN RAILWAY ASSOCIATION. Secretary, Clement C. Smith, president Columbia Construction Company, Milwaukee, Wis.

WISCONSIN INDEPENDENT TELEPHONE ASSOCIATION. Secretary, J. C. Crowley, Jr., Superior, Wis.

DATES AHEAD.

National Electrical Contractors' Association. Next meeting, Chicago, Ill., July 15-17.

Michigan Electric Association. Annual meeting, Grand Rapids, Mich., August 18-21.

International Association of Municipal Electricians. Annual convention, Detroit, Mich., August 19-21.

Ohio Electric Light Association. Annual convention, Put-in-Bay, Ohio, August 25-27.

Colorado Electric Light, Power and Railway Association, Glenwood Springs, Col., September 16-18.

American Society of Municipal Improvements. Annual meeting, Atlantic City, N. J., October.

Illuminating Engineering Society. Annual convention, Philadelphia, Pa., October 6-7.

American Street and Interurban Railway Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Engineering Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Manufacturers' Association. Annual convention, Atlantic City, N. J., October 12-16.

American Electrochemical Society. Fall meeting, New York city, October 30-31.

Record of Electrical Patents.

Week of June 30.

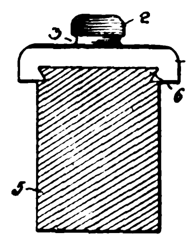
891,825. ELECTRIC-WIRE SPLICER. Conrad J. Dorff, Chicago, Ill. A connector formed of a strip of metal with beveled edges reversely bent to form four parallel tubes.

891,833. OIL-SWITCH. Edward M. Gerry, Norwood, Ohio, assignor to the Bullock Electric Manufacturing Company. The resistance units and contact segments are submerged in a tank of oil.

891,847. DYNAMO-ELECTRIC MACHINE. Emil Mattman, Norwood, Ohio, assignor to Allis-Chalmers Company and the Bullock Electric Manufacturing Company. Means are provided for supporting the cross-connectors between the brush-holders, and independent means for locking the brush-holders.

891,906. ARMATURE CORE. John F. Card, Three Rivers, Mich., assignor to the Sheffield Car Company, Three Rivers, Mich. The core discs have registering openings arranged in series and with radial projections forming channels to receive the armature coils.

891,948. ELECTRIC FIRE ALARM AND THERMO-INDICATOR. Alfred H. McNeil, Highams Park, England. The thermostat arms move plungers and close the alarm circuit.



891,955.—INSULATOR.

891,955. INSULATOR. William C. Sandlin, Andrews, N. C., assignor of one-third to Arthur Moulton and one-third to C. W. Savage. A dovetailed insulator for slipping over a cross-arm.

891,961. TELEPHONE-CONTROLLING DEVICE. Nathan Silverson, New York, N. Y. The contact lever is released by the swinging movement of a second arm.

891,982. ELECTROLYTIC PROCESS FOR THE PRODUCTION OF METALLIC DARK COATINGS UPON METALS. Alexander Classen, Aachen, Germany. After a deposit of sufficient thickness has been obtained the applied potential is lowered.

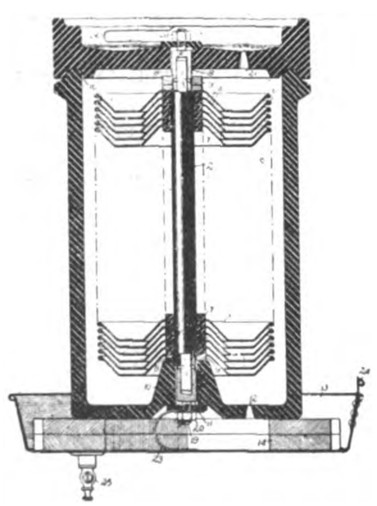
891,995. ELECTROLYTIC CELL. Ralph B. Ingram, Wilkinsburg, Pa., assignor to Westinghouse Electric and Manufacturing Company. A cell built up of a plurality of similar frustro conical plates.

892,016. TROLLEY WHEEL. Robert P. Stark and Charles R. Klingensmith, Creighton, Pa. A wheel with a rectangular bushing.

892,065. ELECTROMAGNET. David L. Lindquist, Yonkers, N. Y. An alternating-current magnet with means for absorbing vibration.

892,167. MOUNTING FOR ELECTRICAL APPARATUS. Malcolm E. Launbranch, Chicago, Ill., assignor to Western Electric Company, Chicago, Ill. A case for holding a telephone set.

892,177. ELECTRIC ILLUMINATOR. Henry J. Mullen, Burlington, Vt. A distributor for electric signs.



891,995.—ELECTROLYTIC CELL.

892,188. PROCESS FOR SEPARATING AND SIMULTANEOUSLY EXTRACTING WATER FROM MINERAL, VEGETABLE AND ANIMAL SUBSTANCES. Botho Schwerin, Frankfort-on-the-Main, Germany, assignor to Farbwerke vorm. Meister Lucius & Brüning, Höchst-on-the-Main, Germany. An electric current is passed through the cells so as to set up electro-osmosis.

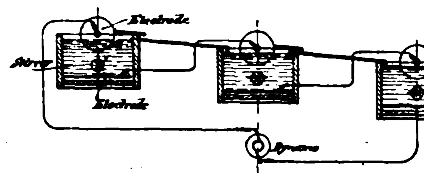
892,203. SIGNALING SYSTEM FOR RAILROADS. Max W. Zabel, Chicago, Ill. A system employing currents of different electrical character for the different signals.

892,204. RAILWAY SIGNALING APPARATUS. Max W. Zabel, Chicago, Ill. The signals are responsive to electric currents of different character.

892,211. PROCESS OF PRODUCING LOW-CARBON ALLOYS. Frederick M. Becket, Niagara Falls, N. Y., assignor to Electro Metallurgical Company. A mixture of a refractory metal and a reducing agent is smelted in an electric furnace.

892,212. ELECTRIC-FURNACE METHOD. Frederick M. Becket, Niagara Falls, N. Y., assignor to Electro Metallurgical Company. A heat-retaining crust of the solidified constituents of the bath is maintained over the surface.

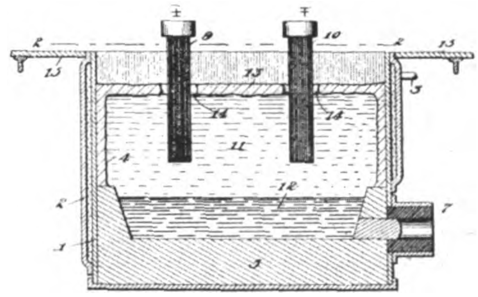
892,272. TROLLEY GUARD AND GUIDE. Charles Latsch, Cleveland, Ohio, assignor of twenty-four one-hundredths to C. A. Muoller and twenty-four one-hundredths to Jos. H. Wenneman, Cleveland, Ohio. Spring-mounted wire guards project above the wheel.



892,188.—PROCESS FOR SEPARATING AND SIMULTANEOUSLY EXTRACTING WATER FROM MINERAL, VEGETABLE AND ANIMAL SUBSTANCES.

892,311. APPARATUS FOR PLOTTING RESONANCE CURVES. Otto Scheller, Steglitz, near Berlin, Germany. A variable inductance and a variable capacity are mounted so as to be simultaneously adjustable.

892,312. SYSTEM FOR RECEIVING UNDAMPED ELECTRIC OSCILLATIONS. Otto Scheller, Steglitz, near Berlin, Germany. A system utilizing the combination of a high-frequency and a low-frequency circuit.

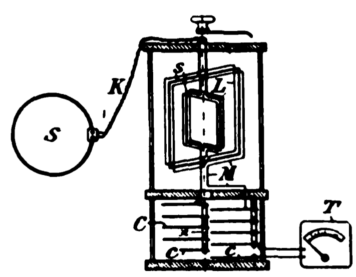


892,212.—ELECTRIC-FURNACE METHOD.

892,319. BINDING POST. Nicholas Sohl, New York, N. Y., assignor to W. R. Ostrander & Company. A spring clip.

892,332. ELECTRICAL INCANDESCENT LAMP. Orlando M. Thowless, Newark, N. J. A non-refractory core is coated with a thin shell of ductile metallic tantalum, producing a filament of high resistance.

892,355. TROLLEY WHEEL. George C. Bourdereaux, Peoria Ill., assignor, by direct and mesne assignments, to Melvin W. Swartz, Peoria, Ill. A wheel with recessed sides.



892,311.—APPARATUS FOR PLOTTING RESONANCE CURVES.

892,359. ELECTRIC-RAILWAY SIGNALING SYSTEM. Yorke Burgess, Washington, D. C., assignor, by mesne assignments, to American Signal Company, Kansas City, Mo. An electromagnetic system for producing signals on trains.

892,371. TROLLEY EAR. Charles W. Eliot, Tampa, Fla., assignor of one-half to William H. Caldwell, Tampa, Fla. A pin is provided for locking the ear boss and the shank.

892,375. ELECTRIC SOCKET SWITCH. Harvey Hubbell, Bridgeport, Ct., assignor to Harvey Hubbell, Incorporated, Bridgeport, Ct. A switch formed of a contact bar and a contact plate, one of the parts being provided with alternate projections and depressions.

THE STEINMETZ STANDARD OF LIGHT.

The science of photometry and the art of illumination have been considerably handicapped by the lack of a really scientific standard of light. The problem of providing a perfectly satisfactory standard is one of the most troublesome that has been encountered by science in recent years. Lord Kelvin said that we know but little about any science until we can measure the factors involved in satisfactory units; and if there be no reliable standard available, the rating of quantities in terms of unsatisfactory standards, while better than no rating at all, still leaves that science in a position where progress is difficult.

In the science of photometry this condition has prevailed for several reasons, the principal one being the difficulty, if not the impossibility, of obtaining a satisfactory physical measure of a physiological effect. This difficulty has been overcome, or minimized, by accepting the situation and agreeing to take as the unit a quantity measurable by its physical effects or properties. Up to this time we have been compelled to be satisfied with light standards not defined by the physiological effect which they produce, but by their physical constants. In other words, we simply say that the light produced by such and such a lamp or candle is to be considered the unit. Such an arbitrary definition can hardly be considered satisfactory and is only acceptable so long as there is none better.

The next step was the suggestion to define the unit of light in terms of the energy radiated by some particular source under specified conditions. This is a decided step forward, yet it does not eliminate all of the disadvantages of the older method. Each source of light has its own peculiarities and gives light of a special quality, and since the eye is more sensitive to certain light rays than to others, a scientific definition on this basis requires that the quality of the radiation as well as its intensity be defined. In other words, the definition of the unit of light on this basis must state not only the amount of luminous energy radiated, but also the relative proportions of the rays of different color. Various suggestions for doing this have been made, the most recent of which, and the one which seems to offer the most promise of success, is that described in the paper read by Dr. C. P. Steinmetz at the recent convention of the American Institute of Electrical Engineers. This method endeavors to define clearly the amount of luminous radiation which is to be the unit and its quality, and suggests a means by which the unit of light thus built up may be obtained.

Dr. Steinmetz's paper is given elsewhere in this issue. His plan is to combine in suitable proportions red, green and blue lights of specified wave-lengths, the rays selected being about equally distant in the spectrum and having ratios in geometrical proportion. These lights are to be mixed in specified proportions so as to produce a white light, though, of course, the exact quality of the light thus produced will be under control and a light differing somewhat from pure white may seem desirable.

To produce the three components, Dr. Steinmetz suggests the use of three mercury lamps, each operated so as to give one of the desired colors. Such a source can, without much difficulty, be brought under the control of the observer and should be much less liable to disturbing influences than any of the arbitrary standards now employed.

Whether such a standard of light is feasible remains to be seen. It would not be simple to use, but if it can be used satisfactorily under the best conditions and in the best-equipped laboratories, its complexity is not a serious objection. Such a source could only be adopted as a primary standard, which would be used at the most but a very few times a year, and for this purpose reproducibility is the most important consideration and outweighs all others. It is certainly to be hoped that the suggestion will be tried at those laboratories where the necessary skill and facilities exist. Its investigation will not be easy, but, on the other hand, there is no apparent reason why the plan should not be successful, and success would mark a big advance in photometric science.

THE DISCUSSION ON EDUCATION.

The discussion on engineering education which took place at the recent convention of the American Institute of Electrical Engineers brought out a good number of interesting ideas on this important subject. It also showed the wide divergence of opinion among the manufacturers, as well as among the teachers. These ideas seem to result from the different views held of the object of such training. There were, on the one hand, those who, it appeared, looked upon the engineering school as a bureau for supplying factory workers; while, on the other hand, there were those who seemed to think that the development of the student, the turning out of men well prepared to become engineers, was the chief end of the technical school.

These two ideas of the aim of the college training explain the different views expressed regarding the value of the scheme produced in Mr. M. W. Alexander's paper. Those who approved of the plan of oscillating the students between the college and the factory approved of it apparently because it seemed to them likely to give a training of the kind which would enable the student more quickly to fall into place in a factory. It should be said that those taking this side of the question do not expect the man thus trained to remain always in subordinate positions, but they argued that the more intimately acquainted the young man becomes with manufacturing methods, and the more he knows of subjects which would be of value to him when connected with a factory, the more likely is he to rise to a position of responsibility and trust. There is, of course, some justice in the position thus taken. The method, no doubt, would, in some cases at least, quickly produce men useful to manufacturing companies—men who would probably quickly become proficient in commercial methods.

On the other hand, is it the main object of the technical school to supply skilled labor for the factory? Is not the purpose of the school to produce trained minds, men fitted to develop into engineers whose work is just as likely to be in some other field as in the factory; and, moreover, since no technical school to-day pretends to turn out skilled engineers, is it not more important to produce a thoroughly trained, logically working brain than one so congested with the details of any special line of work that it finds it impossible to grasp clearly the great problems with which other divisions of engineering have to do, so that its owner would find himself helpless should he not happen to find a berth in some factory? It is not because such practical information is not valuable, but because it could only be acquired by a young man at considerable sacrifice, that the co-operative plan seems undesirable for general adoption. Should not the school direct its efforts toward giving the young man first of all a thorough training in those branches of science which are essential, and should it not, in doing this, guard against such narrow training as will prevent the student from seeing the larger side of his profession? If this part of his education is provided for, then whatever else may be added is so much gained. And it must be remembered that in teaching the applications of science, a certain amount of practice must itself be taught. Nevertheless, the main object of such instruction is to teach principles and develop a capacity for thinking. Practice should be taught to illustrate the application of principles, but principles should not be taught merely to explain the operation of machines. The latter method may produce good followers; the first method only will produce the leaders.

Given time enough, well-trained men could doubtless be produced by any method, but, unfortunately, the time which the young man can devote to his college work is limited. Hence, as Dr. Steinmetz said, he must get at his college what he can not get elsewhere; and, as Professor Morgan Brooks and Mr. C. F. Scott said, in giving him this training care should be taken that the object of the school, which is primarily to train the man, should not be forgotten. No method of cramming him with science, or other subjects, will suffice, and if he can not be taught to think logically and clearly he should be advised to change his study. When dealing with natural forces and engineering material, a false deduction is fatal.

On the other hand, in the endeavor to do as much as possible for the young man in his four short years at college, there is danger that in spreading his attention over too many related lines of work, training in thoroughness and accuracy, so essential for the engineer, will not be given. This point was taken by Mr. B. A. Behrend in the short paper which he read at the convention. It is unfortunately true that too many instructors prefer to have the student stride over a fairly wide field in their work, rather than to cover painstakingly a smaller part of the ground. This is principally true in laboratory instruction, in which the student is expected to become familiar with typical characteristics of certain machines rather than to be able to trace these characteristics with accuracy and certainty. Yet the former knowledge he may obtain in many ways, and he must adjust his knowledge from time to time as the types of machines change, but skill in laboratory work or in computation can only be secured through practice, and if not gained at the school the man is very seriously handicapped until he makes up his deficiencies in these respects, which can usually be done only under considerable difficulty.

In conclusion, it must be said that on the whole the technical schools are really doing excellent work. There is no question that the results might be better, but the schools are improving every year, and if there is such wholesale dissatisfaction as some would have us think, the dissatisfaction is probably because too much is expected. Not every man who is given a degree upon the completion of an engineering course is destined to become a great engineer, and perhaps there would be some economy in sifting out the students more vigorously. On the other hand, there are large numbers of men who wish to obtain training in certain professions, and if these men are earnest and do really learn the essentials of engineering, may they not with some justice demand a degree, the usual recognition for such work?

THE AUTOMATIC PROTECTION OF HIGH-TENSION FEEDERS.

There are a number of protective systems for high-tension feeders and other high-potential apparatus depending for their operation upon different principles. Many years ago, when the alternating system was introduced, a ground indicator was installed showing when the insulation of one side of a circuit was defective. This was generally merely a static voltmeter connected to the two wires and to the ground, and its indications showed simply when the difference in potential between one side of the circuit and the ground was considerably less than that of the other. As the transmission systems increased in size and importance, the necessity of protecting the apparatus from the consequences of heavy grounds or short-circuits became more important, and various other methods have been employed, depending upon the character of trouble to be protected against. Thus, the reverse-current relays are used to prevent damage from the forcing of a current in the wrong direction through the apparatus, while the various types of overload and underload relays are used generally to disconnect feeders or other apparatus when the load exceeds or falls below certain values.

Another system of protection is attracting a good deal of interest in England at this time, as the principle it operates upon is different from those which have been mentioned. This is known as the Merz-Price system. It was referred to briefly in the ELECTRICAL REVIEW of June 20 and at greater length in the issue for June 13. The principle depended upon is the unbalancing of the load at the two ends of a single feeder. A differential relay is installed, the current through one coil, or set of coils, depending upon the load at one end of the feeder, while the current through the other coil or set depends upon the load at the far end of the feeder. For this purpose it is necessary to run a pilot wire the length of the feeder. The objection to this is not very serious, since such wires are often installed anyhow. The advantages obtained by this system are that it insures the disconnecting of a feeder whenever it becomes short-circuited or grounded, while it renders the same feeder capable of carrying considerable overloads without being disconnected. The system is thus selective in the sense that it picks out trouble on the feeder and ignores all troubles beyond it.

SINGLE-PHASE RAILWAY IN ENGLAND.

The single-phase railroad has made very creditable progress both in this country and on the continent of Europe. A number of different systems have been installed, the differences generally consisting of the method adopted for compensating for armature reactions and improving commutation. So far the reports of the operation have been encouraging, but it is yet too soon to say whether any one type of motor is better than all the others or whether some further modification may be found desirable. One thing is evident, the system is to be given a thorough trial and will stand or fall on its own merits.

For these reasons it is interesting to notice the putting into service of the first single-phase railway system in England. This was described briefly in the ELECTRICAL REVIEW for June 27, the Siemens system being employed there, utilizing Westinghouse motors.

The selection of a single-phase system for this important railroad work is somewhat significant, since the polyphase system was introduced into London many years ago in what was at that time one of the most important electric railway undertakings, and this system has not lacked supporters in England. What it will do in city work should be pretty well known by this time, and the performance of the new equipment will enable British engineers to compare the two systems. Moreover, since the direct-current system is used in England for a good deal of heavy work, the outcome of the contest for supremacy will be watched with interest.

A HOME FOR THE INSTITUTION OF ELECTRICAL ENGINEERS.

We extend our sincere congratulations to our British brethren of the Institution of Electrical Engineers upon securing a suitable society home. A building, in many ways well adapted to the needs of the institution, has been obtained, and before many days have passed there will, we hope, no longer be need to trespass upon the hospitality of a sister society. The building is one owned by the Royal College of Physicians and Surgeons. It is excellently situated on the Victoria Embankment, and with some remodeling will meet every requirement. We trust that the impetus given to the institution by this step will make the financial burden thus assumed lighter than anticipated and that it may move with quickened strides to an even stronger and more influential position than the enviable one it now holds.

OHIO ELECTRIC LIGHT ASSOCIATION.

FOURTEENTH ANNUAL CONVENTION, HOTEL VICTORY, PUT-IN-BAY, LAKE ERIE, AUGUST 25, 26, 27.

The following programme has been announced for the fourteenth annual convention of the Ohio Electric Light Association, which will be held at the Hotel Victory, Put-in-Bay, Lake Erie.

Tuesday, August 25, 10 A. M.—Meeting of all committees for organization and work.

TUESDAY AFTERNOON.

First session, 1.30 o'clock.

President's address.

Announcements.

Paper, "Gas Engines in Central Station Work." William M. Adams, Citizens' Gas and Electric Company, Elyria, Ohio.

Paper, "Report on Gas-Producer and Oil-Engine Plants." B. H. Smith, Lexington Electric Plant, Lexington, Ohio; B. H. Gardner, Dayton Lighting Company, Dayton, Ohio.

Question Box.

ENTERTAINMENT FOR TUESDAY.

For the ladies—Afternoon, card party. For all—4 P. M., Bathing Beach; evening, ball, reception, singing.

WEDNESDAY, AUGUST 26, 9 A. M.

Appointment of committees.

Paper, "How Can We Best Increase Our Business?" F. H. Plaice, Hastings, Mich.

Paper, "Best Ways and Means of Getting Out and Keeping Out Private Plants in Central Station Territory." B. H. Gardner, Dayton Lighting Company, Dayton, Ohio.

Paper, "Electric Signs, Outlining and Other Special Uses of Electricity, as an Adjunct to Profitable Central Station Work." J. C. Rothery, East Liverpool Traction and Light Company, East Liverpool, Ohio; C. A. Elliott, Dayton Lighting Company, Dayton, Ohio; Mr. Engle, Youngstown Consolidated Gas and Electric Company, Youngstown, Ohio.

Question Box.

12.30 P. M.—Serving of light luncheon in convention hall, programme to be taken up immediately after.

Paper, "Should Central Stations do Wiring?" Edward F. Gwynn, Delaware Electric Light and Power Company, Delaware, Ohio; C. C. Custer, Miami Light, Heat and Power Company, Piqua, Ohio.

Paper, "Illuminating Engineering." J. S. Codman, Boston, Mass.

Paper, "Report on Experience of Central Stations with Tungsten Lamps."

Question Box.

Entertainment for Wednesday, for the ladies, 10 A. M., visit to the caves and other points of interest. 12.30 P. M., special luncheon for the ladies in the main dining room. Afternoon, for all, Bathing Beach, 3 o'clock. Evening, medley of fun, bridge whist, music, impromptu vaudeville.

THURSDAY, AUGUST 27, 9 A. M.

Reports of committees.

Election of officers.

Paper, "Some of the Causes of Failure in Municipal Lighting Stations." D. L. Gaskill, Greenville Electric Light and Power Company, Greenville, Ohio.

Paper, "Grounding Alternating-Current Secondaries." L. Clifford Anderson, Franklin Electric Light Company, Franklin, Ohio.

Question Box.

AFTERNOON SESSION, 2 O'CLOCK.

Paper, "Gas and Gasolene Competition, and Best Ways to Meet It." Fred Leslie, Muncie Electric Light Company, Muncie, Ind.

Paper, "Experience with Luminous Arc Lamps." C. H. McKay, Toledo Railway and Light Company, Toledo, Ohio.

Question Box.

Entertainment for Thursday, for ladies, morning, band concert; afternoon, euchre party, bowling. Evening, grand banquet for all as the guests of the Association with electric vaudeville between courses.

Demands Return of Fees.

The Indiana & Michigan Electric Company has filed a suit against the state of Indiana for the recovery of $5,760 collected from the plaintiff company as organization fees. The suit is to be a friendly one to test part of the corporation law. The plaintiff company was incorporated May 11, 1907, with a capital stock of $1,915,500. On June 21 and 22 of that year it was merged with the Elkhart Electric Company, capitalized at $150,000; the South Bend Electric Company, capitalized at $150,000, and the St. Joseph & Elkhart Power Company, capitalized at $250,000. F. A. Sims, secretary of state, refused to file the merger agreements until the company paid separate fees for each merger. The company contended that only one merger fee could be collected, as the mergers were made at the same time. It is to be alleged by the plaintiff in the suit that the action of the secretary was not legal. The fees were paid by the company under protest. The case will probably come up for hearing in September.

Side-Door Cars to Be Tried Out in New York Subway.

A final order providing for side doors in New York city subway cars was issued July 10 by the Public Service Commission for the First District. As a beginning, it was ordered that sixteen cars be so equipped. These will make up two express trains, and afford an opportunity to study the advisability of the change, which was recommended by Bion J. Arnold.

The terms of the order provide that the cars shall have four doors on each side. Two of the doors shall be in the position of the doors now in use, and two additional doors on each side shall be placed not less than one nor more than two doors' width from the doors now in use. The company, says the order, shall equip these cars with pneumatic or other mechanical or electrical devices, so arranged as to open and close the doors quickly and automatically to signal the motorman when the doors are closed.

Continuing, the order says that the sixteen cars shall be completed and ready for operation not later than October 15. The reconstructed cars are to have conspicuous signs, informing passengers that the doors near the end of each car are entrance doors, and the doors near the middle are exit doors.

In closing, the order states that the cars shall be operated daily on the express service during the morning and evening rush hours.

Mr. Arnold has estimated the cost of transforming the present cars at $1,500 for each of the 500 composite cars, or $750,000; and $2,000 for each of the 350 steel cars, or $700,000, a total of $1,450,000. General manager Hedley of the Interborough Rapid Transit Company put the cost at not less than $1,800,000.

The order was adopted on the report of Commissioner Eustis, who had indicated its nature at the argument before the commissioner on June 29.

Independent Telephone Merger.

According to the Cleveland *Plain Dealer* a merger of independent telephone properties extending from the Mississippi River to the Atlantic seaboard and embracing properties worth over $100,000,000 is again under way. Options have been secured, it is claimed, on the Frontier Telephone Company of Buffalo and on several eastern companies, forming a through chain of long-distance lines and local exchanges to New Jersey. Agents of the promoters have been endeavoring to secure an option on the independent plant at Detroit. St. Louis capitalists, it is thought, are represented in the new merger and will contribute the Kinloch system of that city.

Regulations for Street Cars in Washington, D. C.

Widespread interest will doubtless attach to the regulations for the street railways of Washington, D. C., which were issued on July 10 by the Interstate Commerce Commission. By act of the last session of Congress these railways were put under the control of the commission, which has had a special committee engaged lately in making inquiry into what regulations were necessary. The regulations issued will, in all likelihood, be given close attention in all municipalities in the country where street-railway regulation is a problem. The principal features of the commission's order are:

1. Every street-railway car operated in the District of Columbia shall be fully equipped with front pick-up fenders of the Blackistone, Claude, Tobe, Preusser or Parmenter pattern, and with wheel-guard fenders of the Brightwood automatic, the Blackistone, the Eldridge Smith, the Tobe or the Parmenter improved pattern; provided, that any street-railway company may substitute for the above any other fender or wheel guard which may hereafter be approved by the Interstate Commerce Commission.

2. Every street-railway car operated in the District of Columbia must be so constructed or altered that a clear space of fifteen inches in height above the rails is provided between the wheel guard and the adjacent end of the car, in order to allow the effective action of the wheel guard.

3. Platforms of street cars shall be guarded by gates of a construction and operation approved by the Interstate Commerce Commission.

4. The fenders must be kept in thorough working order and in good repair when in use.

No street car shall move at a greater rate of speed than fifteen miles an hour in the city of Washington, nor at a greater rate of speed than twenty miles an hour in the suburbs of the city. Street cars shall not exceed a rate of speed greater than six miles an hour at street crossings. No motorman or conductor shall refuse to stop to take up a passenger unless all the seats in the car or train are occupied.

6. Whenever street railroads cross each other all cars or trains bound north or south shall have the right of way over trains or cars bound east or west, and all motormen shall, on approaching intersecting crossings, stop their cars or trains and see that the way is clear before crossing; provided, that the provisions as to the right of way shall not apply where branches of the same street railway cross each other.

7. Flagmen shall be stationed at the crossings of all street-car lines when in the judgment of the Interstate Commerce Commission the public safety requires the same. And from and after the direction of the commission to any street-railway company to station a flagman at any such crossing it shall be unlawful for any motorman to run or operate any motor-car over such crossing in the absence of a flagman. No street car shall stand upon a street or avenue for a longer period than five minutes unless the way be obstructed, nor stop so as to obstruct a street crossing or intersecting street; and no street car shall follow a preceding car moving in the same direction at a less interval than 100 feet, unless coupled thereto. Every street car in motion after sundown shall have two lights, one displayed at each end thereof.

Public Service Commission Directs Rehabilitation of Plant.

The Public Service Commission of the Second District of New York has just issued a decision which is of great interest as indicating its attitude with regard to the protection of properties of existing companies and the conditions upon which competing companies will be permitted to operate in small communities.

Complaint had been made at hearings of alleged poor service given by the Albion Power Company in that village, and only recently a receiver was appointed for the company. The Swett Electric Light and Power Company, of Medina, has asked the commission for permission to furnish electric lights in Albion, as a result of the troubles of the local concern.

After investigation and upon the earnest request of the receiver and bondholders of the existing company, the commission has given the receiver of the Albion Power Company an opportunity to begin at once and complete, within thirty days, certain improvements which must be installed within sixty days. The application of the competitive company is held open for thirty days. If at the expiration of that time the improvements required have not been undertaken to the satisfaction of the commission, the application of the Swett company will again be taken up.

The Albion company is required to rehabilitate its water power plant, make necessary repairs to boilers and purchase and install a 900-kilowatt belt-driven generator, with other necessary appliances, and to purchase and put up the additional distribution copper necessary to furnish proper service in Albion. The company is also required to install the following apparatus: Three fifty-kilowatt 6,600-13,200-volt transformers with necessary connections; new arc light system, proper switchboard devices on its entire system, exciter regulators, single-phase feeder regulators, to conserve its water power and increase its availability so that the maximum water power will be available during the evening hours of greatest consumption.

If this work is completed within sixty days and the commission is satisfied that the village is receiving proper service, the application of the petitioner will be denied. Otherwise the pending application will be brought up for further action.

Bombay Electrical Development.

In September, 1905, the Bombay Electric Supply and Tramway Company started business in Bombay, India, with about seven miles of mains in the European section of the city. The advantages of electricity were speedily appreciated, and by the end of the year, installations amounting to the equivalent of nearly 20,000 eight-candle-power lamps had been coupled to the mains, including over 1,000 electric fans. During the past two years, although very busy with the electrification of the horse tramway system, the company has developed its general electrical supply at a rapid rate, as may be seen in the following table:

Date.	Mileage of Streets Served by Mains.	Equivalent Number 8 Candle-Power Lamps.	Number of Electric Punkahs.	Brake Horse-Power of Electric Motors.
January 1, 1906..	7½	19,778	1,050	69
January 1, 1907..	8	58,849	2,110	219
April 1, 1908.....	11¾	[1]100,000	4,000	474

[1]Approximate.

The increase in the consumption of energy is also shown by the fact that in 1907 there were sold 1,233,671 electrical units, as against 488,477 in 1906. Arrangements have been made for providing supply in other districts of the city. The following retail rates are now in force:

(*a*) For general purposes, eight annas (anna = two cents) per unit for the number of units equivalent to one hour's use per day throughout the month of the maximum demand as shown by indicator, and two annas per unit for all units in excess of this quantity as shown by difference between meter and indicator readings for the month.

(*b*) For elevators, four annas per unit flat rate.

(*c*) For bona fide industrial motive power installations of five brake horsepower and upward, two annas per unit flat rate.

PRIMARY STANDARD OF LIGHT.[1]

BY CHARLES P. STEINMETZ.

Light is not a physical quantity, but a physiological effect, that of certain wave-lengths of radiation, and therefore can not be expressed in absolute physical units; it must be measured by comparison with an arbitrarily chosen standard of physiological effect. As a result thereof even with the best existing primary standard of light, the amylacetate lamp, the difficulties of reproduction, and maintenance of its constancy, are such as to involve errors very far beyond those considered permissible in physical measurements. A radical increase in the accuracy of reproduction and maintenance of a primary standard of light appears possible only by relating the standard of light in such manner to physical quantities, that it can be determined by energy measurements.

This led to the recommendation of defining the primary standard of light by the energy of radiation. It requires, however, a definition of the quality of radiation, since the physiological effect of radiation has no direct relation to the energy of radiation: One watt of radiation of a wave-length from the centre of the visible range gives a far higher physiological effect, that is, more light, than one watt of a wave-length near the ends of the visible spectrum. This is not merely a function of the quality or color of the light, as light of the same intensity and same color, identical physiologically, may be entirely different physically, and therefore represent a different amount of power. For instance, the physiological effect of white light is produced by the combination of all colors of the spectrum, but also by an infinite number of combinations of two, three, or more spectrum colors; and these physically different forms of white light, while indistinguishable on the photometer screen, and thus physiologically identical, represent different amounts of radiation power per unit of physiological effect, or per candle-power. The same reasoning applies to colored light. The power of the visible radiation is, therefore, not a measure of light.

The definition of the absolute unit of light as the physiological effect of one watt of power of visible radiation, requires, therefore, an arbitrary definition of the distribution of power throughout the visible range. As such distribution of power through the visible range, may be chosen that of the black-body radiation at a definite temperature, and the temperature measurement may be eliminated by specifying the energy-ratio between two definite regions of the spectrum. For instance, such a definition would be:

The unit of light is that given by a black body radiating one watt of power between the wave-lengths of thirty-nine and seventy-two, under the condition (that is, at the temperature) where the power of radiation from wave-length thirty-nine to fifty-five bears to that from fifty-five to seventy-two the ratio a.

It does not appear to me that such a standard would be very satisfactory, and for the following reasons:

1. Though the intensity of radiation at the red end of the spectrum is very high, the physiological effect is very small, and an inaccuracy at this limit would therefore seriously affect the result.

2. The absorption constant of glass or any other envelope is different for different wave-lengths.

3. Any deviation of the radiator from the black-body radiation vitiates the result.

4. The color of the light would not be white, but yellow, due to the temperature limitation imposed by the radiator.

A more satisfactory primary standard of light, based on measurement of radiation power can, as I believe, be produced by selecting three primary colors of the visible spectrum. Let these colors be of definite wave-length, about equidistant from each other and of such character that they can be absolutely reproduced at high intensity, as the spectrum lines of a luminous gas or vapor. Then define the unit of light as that given by one watt of power radiated at these three wave-lengths, in definite proportions, chosen so as to give white, or yellowish-white, light. That is, the primary unit of light is the physiological effect, as observed on the white photometer screen, of one watt of power, radiated in the three definite wave-lengths A, B, C, in the proportion $a \div b \div c$.

The adoption of this standard of light would eliminate the sources of error which now affect the primary flame-standard. The radiation density or light flux intensity of the three primary colors is measured separately before they are combined on the same photometer screen, and the accuracy of determination would be limited only by that of physical measurement of radiation energy, by bolometer or otherwise.

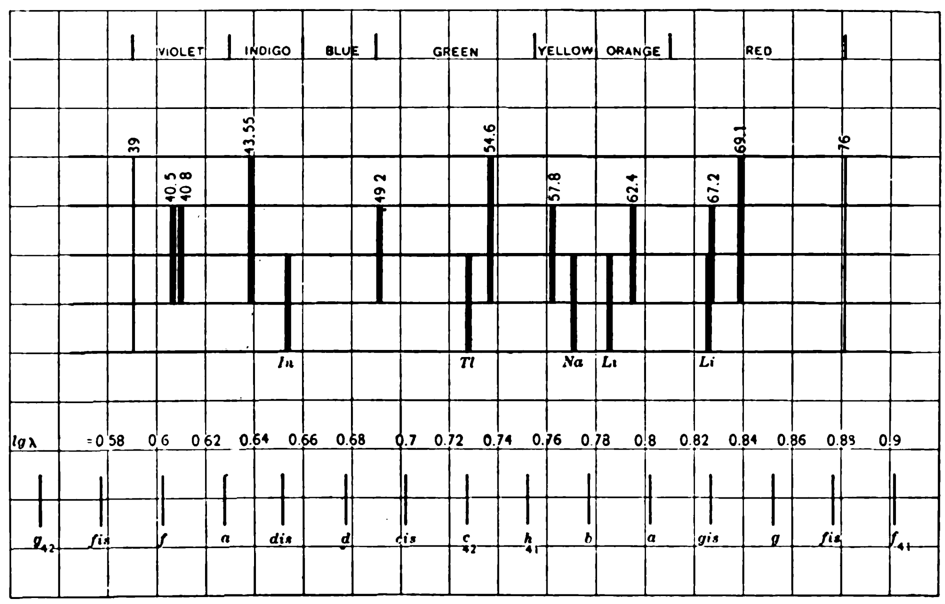

FIG. 1.—CERTAIN OF THE BRIGHTER LINES OF THE SPECTRUM SHOWN IN GEOMETRIC SCALE.

This standard of light requires three sources of monochromatic radiation, which can be maintained constant with any desired exactness. This requirement seems fulfilled by the mercury lamp. When reasonably protected from air drafts, changes of surrounding temperatures, etc., the intensity of radiation of a mercury lamp remains extremely constant at constant current, and, for minor variations of current, varies directly as the current, while that of the incandescent lamp varies as a high power of the current. It must be considered that a reproduction of the same intensity in the lamp is not required, as is the case with standard lamps,

[1] A paper presented at the twenty-fifth annual convention of the American Institute of Electrical Engineers, at Atlantic City, N. J., July 2.

since the mercury lamp is merely the source of monochromatic light, and its intensity is measured and adjusted.

I should therefore recommend mercury lamps as the sources of the three monochromatic radiations, which combined give the primary standard of light.

Approximately, some of the brighter lines of the mercury spectrum are shown in Fig. 1 in geometric scale; that is, with the logarithm of wave-length as abscissas. When investigating the combination of different frequencies to a resultant effect, this rational scale, which is the scale of acoustics, is preferable.[1]

In Fig. 2 the mercury spectrum is given in polar co-ordinates with the octave, or the ratio of wave-lengths two divided by one, represented by 360 degrees. For illustration, the frequency denotations of acoustics are recorded in Figs. 1 and 2; that is, one tone represents thirty degrees.

For comparison the spectrum lines of Li, Na, Tl and In are also shown.

[1] The usual way of recording spectra, with the wave-length, or the frequency as abscissas, is irrational; one wave-length in the ultraviolet represents a far greater range than in the ultrared. The infinite number of radiations of shorter wave-length, or higher frequency than the visible, are crowded into a finite space, when using wave-length as abscissas, while the lower frequencies or longer waves cover the whole range from the ultrared to infinity. The reverse is the case with the frequency as abscissas. The intensity curve of radiation, measured and recorded with the wave-length as abscissas, is different, and its maximum at a different point, than the intensity of the same radiation plotted with the frequency as abscissas. The rational scale of any periodic quantity is the geometric scale, where equal intervals represent equal percentual increase or decrease; that is, the logarithmic scale. This was realized long before science existed: it is the scale used in music, with the octave; that is log. 2, as abscissas.

Of the spectrum lines of mercury, of approximate wave-lengths:

40.5; 40.8; violet.	43.55; blue.	49.2; 54.6; green.	57.8; yellow.	62.4; orange.	67.2; 69.1; red.[1]

the lines:

Blue	43.55
Green	54.6
Yellow	57.8

are the most prominent. The three red lines, and many more red lines, appear only at higher temperature, as in the Heraeus quartz lamp.

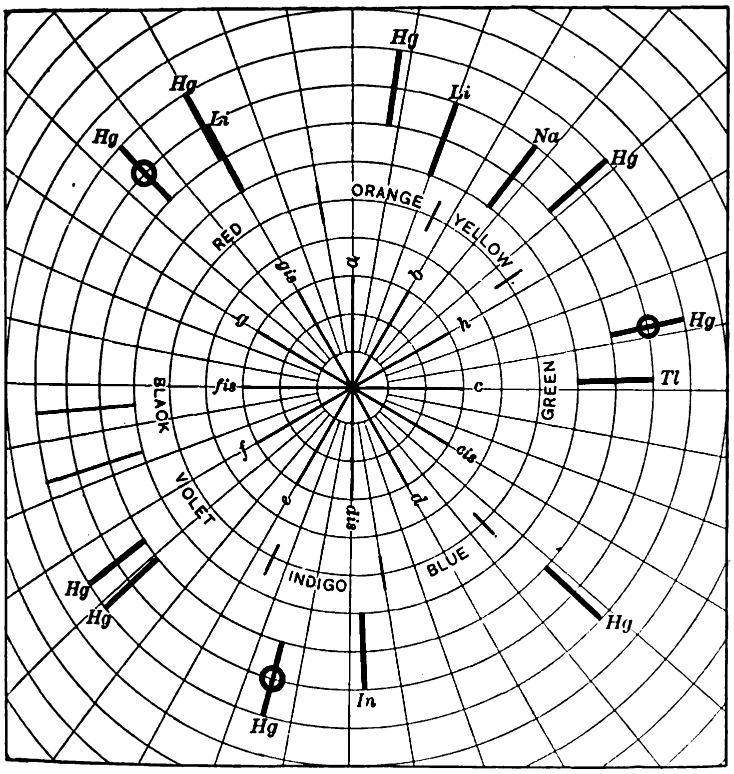

FIG. 2.—THE MERCURY SPECTRUM SHOWN IN POLAR COORDINATES.

The three spectrum lines of mercury:

Blue	43.55
Green	54.6
Red	69.1

which are about equidistant and therefore appear the most suitable as primary colors for a standard of light.

Two low-temperature mercury lamps would be required for the blue and the green, and one high-temperature quartz lamp for the red. These would be maintained at constant radiation by maintaining the current constant, and also the condition of ventilation and surrounding temperature.

Resolved by a prism, the blue line of the first, the green of the second, and the red of the third lamp are thrown on the same white screen, and their radiation energy measured separately. What energy proportion to select for the three colors, to give a color suitable for a primary standard, remains to be investigated. Probably a yellowish-white would industrially be most convenient.

[1] The wave-lengths of these red lines require redetermination. Some of the other lines are twins.

It is interesting to note that such a selection of three primary colors as components of a standard of light would also allow an exact numerical expression of the physiological color of any light, by the ratio of the three intensities, $a \div b \div c$; that is, the color of light could be measured by varying the intensities of the three standard wave-lengths until their combination, on the white screen, becomes identical in color with the observed light.

The State's Water-Power Right.

A very interesting and important suit has been brought by the Fulton Light, Heat and Power Company, of Fulton, N. Y., against the state of New York, and action is being taken in the Court of Claims. The power company alleges that $3,200,000 damages is due it for the appropriation by the state for the barge canal of private property in the bed and waters of the Oswego River.

The power company is one of sixteen users of water power at Fulton, and there are a number of water-power users at other points affected in the same way. Upon the result of this action depends the ability of the state to complete the building of the barge canal. George F. Decker, deputy attorney-general, has made the following statement:

"It is doubtful if the interests of the state were ever more boldly challenged. The state claims that the Oswego River was by nature and immemorial usage a public highway before the river was canalized, that its bed and waters were never bartered away, or, if they were, that the grant was subject to navigation uses. The state also claims that if this river ever became private property, it was reappropriated by the state when it was canalized in 1826.

"If the state's position is unsound, it will probably result in preventing the completion of the present canal enlargement as well as the undertaking of any state improvement of navigation hereafter, because of the increasing value of water power with wood gone and coal going. This case is the first in a very long time which has arisen directly against the state and wherein this question has been involved. It will determine whether the water power of our larger rivers and of the canals is held as an irrevocable monopoly in private hands."

THE RELATION OF THE MANUFACTURING COMPANY TO THE TECHNICAL GRADUATE.[1]

BY B. A. BEHREND.

Even though in times of business depression it may seem to us as if there were more applicants than positions, yet no thoughtful man denies that, while the number of positions in such times may have greatly decreased, the importance of filling them by thoroughly capable and competent people has correspondingly increased. For example, a position which, in times of exceptional prosperity may be filled fairly well by an average man, will be sorely in need of a man of exceptional ability when business prosperity is on the wane. If there is any one fact more patent than another it is the fact that there is always room at the top of the ladder for men of integrity, of moral courage, and of intellect. There are plenty of men who possess any one of these qualities; there are few who possess all three, and these the manufacturing companies, or the world at large, most require. In their anxiety to secure the raw recruits for officers thus endowed, the manufacturers turn of necessity to the universities and their graduates.

It must be granted that the colleges possess an almost unlimited potentiality for improving the human material turned over to them to shape and polish, and, it seems to me, considering the results obtained, they are doing very well in this shaping and polishing process. But they are not always supported in the right direction by the manufacturing companies. To allude to one instance only, I refer to the manner in which the manufacturing company seeks the young graduate, instead of letting him do the seeking. He thus gains, at the outset, an exaggerated idea of his importance, and an independence which is not conducive to the development of those qualities which make thoughtful and painstaking men. Our graduates are chiefly deficient in these qualities, and this is due, not so much to an innate deficiency in this direction, as to the fact that the incipient faculty has never been properly awakened and cultivated. There is abroad among our colleges and their graduates a most ominous disdain for painstaking accuracy and devotion to laborious detail, so essential to all really great work in engineering. The wish to take someone else's thought and work and make it a commercial success, which is so prominent a feature of our business life, is easily explainable, though not so easily excusable. Men of ability realize that the same effort turned into the channels of commercial work will be productive of better returns than they would obtain by painstaking working out, for instance, the design and construction of electrical machines. In this case, even though their work may have met with eminent commercial success, our business methods are not much concerned with a debt of gratitude or obligation to the men that did the building up. Here lies a menace to the stability and continued prosperity of our manufacturing industries which must, in time, be remedied, lest it produce a far-reaching result in discouraging graduates of our colleges from the pursuit of new and important creative engineering work, with the result that we will have to draw on other countries for a supply of well-trained engineering brains.

The managers of our manufacturing plants can do as much toward the development of right views and proper education as can the teachers and organizers of the colleges. The former need to study more sympathetically the condition of the latter, and *vice versa*. There are very poor pretenses of both managers and teachers in this world, and it is obvious that "the highest gifts are not always brought to the highest place." Education is a very good thing, but it can not give the qualities which it should develop. Those who, like the writer, have been instrumental in the building up of large manufacturing organizations, recognize that the absence of moral qualities frequently mars a successful career, as frequently, perhaps, as the absence of purely intellectual qualities. Success often accompanies the work of men possessing ability, untempered by scrupulous restraint. Examples of this kind, so plentiful, have left a detrimental impression on the minds of aspiring young men. The thoughtful words of James Bryce, that this country " . . . has the glorious privilege of youth, the privilege of committing errors without suffering from their consequences," remind us that many of our faults are not visited upon us with the unerring justice they deserve, because of the actual and potential wealth of this country in its present state of youthful and vigorous development. But let us not be deceived permanently into believing that, with our population increasing in geometric progression and thickening in our cities and manufacturing centres, many of the crude and lavish methods, despite which our industry is the most flourishing in the world, can be permanently retained without doing infinite harm. Space does not permit me to do more than to indicate the line of thought I wish to suggest. We need both character and intellect in our graduates, which should be cultivated by close co-operation between the manufacturing companies and the colleges, but for creating which no panacea has yet been devised.

[1] A paper presented at the twenty-fifth annual convention of the American Institute of Electrical Engineers, Atlantic City, N. J., July 2, 1908.

Theodore N. Vail on Business Conditions in the West.

Theodore N. Vail, president of the American Telephone and Telegraph Company, has returned from an extensive trip throughout the West, having visited from Mississippi to the Coast and from Texas to the extreme Northwest. In speaking of the business conditions, says the New York *Journal of Commerce,* in that part of the country, Mr. Vail said:

"So far as basic conditions go in that section, there is absolutely no reason for a depression. I have been taking a broad view of the West for the last thirty years, and never in that time has the outlook been better than it is now.

"Crops are promising, indeed; in fact, the original producers, as the farmer and the cattle and sheep raiser, are in better shape than I have ever known them. Developments in every phase during the last five to eight years are beyond comprehension and belief. Cities as widely apart geographically as Dallas, Tex., and Spokane, Wash., have expanded in every direction.

"The floods have not done any great harm on the whole. It is true that the railroad losses can not be offset, but the sections needing moisture have profited more than other sections not needing it have suffered. Dry farming places—the semi-arid lands—were never in such luxuriant growth, and the grazing areas are likewise in the fullest flush of growth.

"The public utility and the public service corporations have been the central factor in the business situation, and they continue to remain the dominating element, and many of their problems have not yet been solved. This is the disquieting feature. What brought this about and how it was brought about everyone now knows."

Taking up the companies whose interests he serves, President Vail says: "Our business shows relatively no falling off. The business of the associated Bell companies is better this year than last year. There is a good demand for the better class of telephones; in fact, we have all the business of that kind we can do. As for new construction, the associated companies will do twenty-five to thirty per cent less than last year. The figures will fall even below our estimates made at the beginning of 1908."

FINANCIAL REPORTS OF ELECTRIC COMPANIES.

LEXINGTON & INTERURBAN RAILWAY COMPANY.

The report of the Lexington & Interurban Railway Company, of Lexington, Ky., for the month of May and five months ended May 31 shows May gross of $50,271; expenses, $35,180; May net, $15,091. Five months' gross, $225,340; expenses, $154,458; five months' net, $70,882, an increase for the five months of $5,226.

NORFOLK & PORTSMOUTH TRACTION COMPANY.

The report of the Norfolk & Portsmouth Traction Company, Norfolk, Va., for the month of May and five months ended May 31 shows May gross of $152,175; expenses, $90,262; May net, $61,913. Five months' gross, $711,092; expenses, $448,912; five months' net, $262,180.

TWIN CITY RAPID TRANSIT COMPANY.

The report of the Twin City Rapid Transit Company, Minneapolis, Minn., for the month of May and five months ended May 31 shows May gross of $527,393; expenses, $254,577; May net, $272,816; charges, taxes and preferred dividend, $126,972; May surplus, $145,844. Five months' gross, $2,429,348; expenses, $1,265,571; five months' net, $1,163,777; charges, taxes and preferred dividends, $621,178; five months' surplus, $542,599.

AMERICAN TELEPHONE AND TELEGRAPH COMPANY.

For the five months ended May 31 the American Telephone and Telegraph Company reports an increase of 0.32 per cent in net earnings for dividends on the augmented capital stock. The net earnings available for dividends were equal to 5.57 per cent on the outstanding stock, against 5.25 per cent on nearly $21,000,000 less stock in the first five months of 1907. The current year will be one of greatly decreased figures on the score of new construction and extensions. In the last eight years nearly $352,000,000 was devoted to this purpose. The tendency to let up in expansion began early last year, when expenditures for new construction on the part of the Bell system were $30,000,000 less than in 1906. Financial requirements have been satisfied until January, 1909, and it is stated no new funding operations will be needed until 1910, when the company's note issue of $25,000,000 will come due.

PHILADELPHIA RAPID TRANSIT COMPANY.

The gross earnings of the Philadelphia Rapid Transit Company for the fiscal year ended June 30 were $18,228,000. This is an increase of $132,500 over the previous year. Although the official figures for the net earnings have not been made up, it is understood that operating expenses increased about ten per cent over last year, in which case they amounted to approximately $11,000,000. On this basis net earnings were about $7,228,000, compared with $8,049,016 in the previous year, a decrease of 11.3 per cent.

TOLEDO RAILWAYS AND LIGHT COMPANY.

As a part of the plan of the protective committee of the bondholders of the Toledo Railways and Light Company, Toledo, Ohio, the July 1 interest on the $4,866,000 consolidated first-mortgage four per cent bonds of the company will not be paid. The July 1 interest on the $1,066,000 Toledo Consolidated Street Railway first mortgage five per cent bonds and that on the $4,234,000 Toledo Traction Company first consolidated mortgage five per cent bonds will be paid. These two latter companies are underlying companies of the Toledo Railways and Light Company. All of these bonds fall due July 1, 1909. Accordingly, the bondholders' committee is anticipating the future by a year. On February 1, 1912, there is an issue of $700,000 Toledo Electric Street Railway Company first-mortgage five per cent bonds that come due.

The earnings of the Toledo Railways and Light Company are showing some slight improvement over those for last year, the increase in the surplus for the five months ended May 31 being $4,570. Now that no dividend is being paid it is believed it will be possible for the company to take care of its floating debt with its earnings. Some of the company's street railway franchises expire in 1909, and others expire from year to year until 1914, by which time all the franchises will have expired unless renewed. Lighting franchises do not expire for several years. It does not seem likely that satisfactory arrangements can be made to refund the outstanding bonds until the city and the company are able to come to terms as to the renewal of the street-railway franchises.

Wireless System on the Amazon.

Wireless telegraphic communication between Lima, Peru, and Iquitos, on the Amazon River, has been successfully established, according to a cablegram received by Eduardo Higginson, Peruvian consul-general at New York.

The National Electrical Contractors' Association Convention.

The eighth annual convention of the National Electrical Contractors' Association was held during the week at the Auditorium, Chicago, Ill. The programme included two open sessions, one on Wednesday morning and one on Thursday morning. Business sessions were held each day, both in the morning and afternoon. At the open sessions papers were presented by George Loring, on "The Electrical Contractor's Opportunities in the Illuminating Field"; by W. H. Merrill, Jr., on "The Relations Between the Underwriter and the Contractor"; by J. R. Cravath, on "Illuminating Engineering"; by Alex Dow, on "The Relations Between the Lighting Company and the Contractor," and by Seth B. Wetherbee, on "The National Electrical Contractors' Association." The extra feature of the convention included a rejuvenation of the Sons of Jove, a ladies' banquet, a men's banquet and an all-day outing to Michigan City.

June Copper Output.

Reports from the various producing mines in the United States, Canada and Mexico would indicate a decrease of 95,961,979 pounds in the production of copper for the first six months of 1908, and a decrease of 118,557,000 pounds as compared with the first half of 1906.

Every month of the year has shown a substantial decline. May approached nearest to last year's figures.

The Boston News Bureau figures the production of copper in the United States, Mexico and Canada for June at 79,431,725 pounds, compared with 96,123,030 pounds in June last year, and 101,666,900 pounds in June, 1906.

The total production, by months, for the first six months of this fiscal year, is estimated as follows:

	1908	1907	1906
January ..	65,900,000	84,935,143	97,296,400
February ..	65,036,750	85,278,160	89,205,800
March	79,105,704	102,495,230	96,480,081
April	87,582,805	96,567,700	98,044,400
May	90,880,300	98,500,000	103,800,000
June	79,431,725	96,123,030	101,666,900
Total ...	467,937,284	563,899,263	586,494,581

For the first time this year the production in Arizona (in June) exceeded last year's figures, amounting to 24,909,000 pounds, as compared with 23,096,000 pounds last year.

Utah also comes forward with new high figures of 8,600,000 pounds, as against about 6,000,000 pounds for June a year ago, and California and Canada both show a slight increase over last year.—*Wall Street Journal.*

Annual Convention of the American Institute of Electrical Engineers—II.

Report of the Fifth and Sixth Sessions, Wednesday, July 1.

THE fifth session of the twenty-fifth annual convention of the American Institute of Electrical Engineers, which was held at Atlantic City, N. J., June 28 to July 2, inclusive, was called to order Wednesday morning, July 1, with Vice-President Armstrong in the chair. The reports of the two preceding days were given in the issues of the ELECTRICAL REVIEW for July 4 and 11. At the Wednesday morning session a number of papers dealing with the construction and operation of electrical machines and the equipment of generating stations were taken up. Two papers were first read dealing with the split-pole converter.

C. A. Adams presented a paper on "Voltage Ratio in Synchronous Converters with Special Reference to the Split-Pole Converter." This is a purely theoretical analysis showing how the field distortion of a split-pole converter does not necessarily involve electromotive-force distortion. Incidentally the author develops a method of analysis by which the direct electromotive force or any one of the alternating electromotive forces is determined analytically from the harmonic analysis of the flux distribution curve, thus establishing a simple and direct connection between the shape of the flux distribution curve and the shapes and magnitudes of the resulting electromotive forces. The author concludes that with the tap connections 180 degrees apart and a large number of slots, an mth harmonic in the flux distribution appears in the alternating electromotive force, but reduced to one mth of its value. The higher harmonics are of little value in changing the voltage ratio. With 120-degree connections, the third, ninth, fifteenth, etc., harmonics do not appear in the alternating electromotive force. With three-part poles and symmetrical distortion there is a definite minimum per cent of electromotive-force harmonics for a given range of voltage ratio, and the fifth harmonic is usually the most prominent. With two-part poles the total per cent of electromotive-force harmonics for a given range of voltage ratio may be made considerably less than for the symmetrical distortion, and as the third harmonic is naturally predominant in this case the employment of the 120-degree connection or of the 180-degree connection with star-connected transformer primaries may result in the practical elimination of electromotive-force or current harmonics. The conditions in this respect may be still further improved by the use of mid-slot connections and a fractional pitch winding.

A paper on "Application of Storage Batteries to Regulation of Alternating-Current Systems" was presented by J. L. Woodbridge. This points out that in many cases where alternating-current generation is employed a regulating storage battery is even more valuable than for direct-current service. This is because alternating-current generation is particularly applicable for long-distance interurban railway work, as in many cases it is developed in water-power plants and transmitted for long distances. Moreover, in many cases of water-power development power is sold on the maximum-demand basis, so that the saving effected by removing peaks and smoothing out the load is particularly valuable. The auxiliary apparatus required in connection with the storage battery adapted for regulating an alternating-current system may also be used for changing the frequency or controlling the power-factor; and, further, the increasing use of gas engines in steel plants offers a large field for the application of storage batteries, since in most cases the large areas served by the plant make it advisable to adopt an alternating-current distributing system. The author then discusses the various alternating-current systems in which storage batteries may be used with advantage and describes suitable means of adapting the battery to regulating the load on the generating station.

The discussion was opened by P. M. Lincoln, who said, with reference to Mr. Adams's paper, that the wave-form of the electromotive force, which was given the most attention, is not the only important feature in a machine of this type. In this type of design there is considerable lost space and the efficiency is decreased. Analytical discussions, such as have been made, do not demonstrate the practical value of this apparatus, as the test of time only will prove its weaknesses and virtues. Mr. Lincoln then discussed the effect of the number of taps in the converter on the harmonics of this wave-form, and said that those 120 degrees apart have less influence than those 180 degrees apart. He does not think that the efficiency of the split-pole converter is any better than that of a machine combined with a booster. Moreover, it is probable that the design will give rise to considerable noise, which it will be hard to prevent. The voltage changes of the machine are slow, and it, itself, is large. While a rotary is desirable, other conditions being the same, the disadvantages of the split-pole converter outweigh its advantages.

A. S. Hubbard said that the system described in Mr. Woodbridge's paper can hardly be taken as accepted practice, as there are only five plants of this general type in the country. One of these, which is not now in operation, was installed primarily to tie together two generators of different voltage and a transmission line. The regulation of the system was erratic. The plant described in the paper is included in the five, but as the conditions existing there are peculiar, it can hardly be taken as a fair example of the use of storage batteries for alternating-current regulation. In a third plant a two-coil regulator of the dynamometer type is employed, which causes the battery to charge and discharge in response to variations of the true energy on the system. The regulation on this system is not good, there being variations of twenty-five per cent above and below the average. In a fourth plant, utilizing water power and developing 13,000-volt, three-phase, twenty-five-cycle current, another type of regulator is employed. There are three current transformers on the incoming high-tension lines with their secondaries connected to a second set of three current transformers back of the switchboard, and provided with sectional secondaries connected to a compensator head. From the compensator head the current is led to the collector rings of a rectifier consisting of an armature with a two-pole winding. This is driven at synchronous speed by a synchronous motor, so that the rotating field set up by the current is fixed in space. Two brushes placed upon the commutator of the rectifier thus deliver a direct current varying directly with the true load on the system, and thus control the charging and discharging of the battery. A second pair of brushes ninety degrees from the former, and connected to an inductive circuit with characteristics corresponding to those of the main circuit, delivers a current which varies with the power-factor of the system, and thus enables the regulator to correct the power-factor of the system by changing the excitation of a synchronous motor or rotary. With this arrangement the load in kilowatts on the generators varies only three and one-half per cent above and below the average. An important feature of the arrangement is that the output of the rectifier does not affect the load on the driving motor at all, nor has the rectifier any motor action. The fifth plant referred to employs a regulator of the same kind, designed, however, for sixty cycles. Mr. Hubbard believes that this method of regulation is particularly suitable for plants driven by water power, gas engines or steam turbines.

W. L. Waters said that the question regarding the installation of storage batteries in a direct-current plant is one of cost. In a mixed plant, however, the chance of breakdown is considerably increased, and this is a serious consideration. Regarding the split-pole converter, he thought one point had been overlooked, and that was the probable difficulty of maintaining satisfactory commutation, and he asked what advantages this machine had over the ordinary arrangement employing a booster.

C. P. Steinmetz said that some surprise had been expressed at the use of what was treated as a newly recognized property of the synchronous converter. However, the reactions depended upon for regulating the split-pole converter have long been known. In the ordinary rotary with fixed brushes, the ratio between the alternating and direct potentials is constant, since the latter is merely the maximum value of the former. If, however, the brushes be shifted from the neutral plane, the direct potential will be lowered, since a part of the armature winding is thus rendered ineffective, while the alternating potential is not changed. The ratio of the two potentials may in this way be changed, but the method is not practicable, since commutation becomes impossible. Another way would be to hold the brushes in a fixed position and shift the poles mechanically, the result of which is identical with the first method described. But there is still another way—that is, to shift the field electrically. If the field poles be divided into two parts and each provided with a separate winding, by varying the relative excitations of the two parts, the position of the magnetic field may be shifted with respect to the brushes and the voltage ratio varied continuously. This is all that is done in the split-pole converter. There is another method of varying the potential ratio, which consists in adding harmonics to the alternating-current wave. The third harmonic is the most useful, and on three-phase converters this harmonic does not get out of the machine, though it causes some additional loss. On six-phase rotaries the harmonic flows through the transformers, but does not get beyond them and transfers additional loss to them. Regarding the criticism made by Mr. Lincoln that the split-pole converter is large, Dr. Steinmetz said that this is a characteristic of all machines designed to have a range of working. They must be constructed so as to carry the maximum current and develop the maximum potential, and hence the size is determined by the product of these two values.

In closing the discussion, Mr. Woodbridge did not agree with all the points made by Mr. Lincoln, and said that the use of a damper to prevent surging of the flux did not interfere with the quickness with which the machine responded to changes of excitation.

Three papers were then read dealing with the construction of alternating-current generators.

B. A. Behrend presented a paper entitled "A New Large Generator for Niagara Falls." This describes the new 6,500-kilowatt generator recently installed by the Niagara Falls Hydraulic Power and Manufacturing Company in the new station at the foot of the falls on the American side, just below the old power-house of the same company. The new machine is interesting because of its high speed, which is 300 revolutions a minute and is greater than that of any other generator at the falls. It is wound for 12,000 volts, three-phase, twenty-five cycles, and will carry a continuous load of 7,320 kilowatts. The generator has been designed for a safe speed of 506 revolutions a minute, which is the runaway speed of the water-wheel. The construction of rotor and stator is described somewhat in detail and some very interesting results of an investigation of the mechanical stress produced in the different parts of the machine by the high speed are given. The guaranteed efficiency of the generator at full load is 96.5 per cent with a power-factor of ninety-five, and 95.9 per cent with a power-factor of eighty-five. Under test the efficiency was found to be 97.83 per cent at full load and ninety-five per cent power-factor, and 97.5 per cent with a power-factor of eighty-five. Temperature tests showed that the temperature will remain within thirty-five degrees of the normal at the rated load and within forty degrees with an output of 7,500 kilowatts.

A paper entitled "Modern Developments in Single-Phase Generators" was read by W. L. Waters. Although single-phase generators have been used for twenty years or more, they have generally been of small size only, and used for lighting work. The recent development of the single-phase alternating-current railway motor has given rise to a new demand for large high-speed, low-frequency, single-phase generators, and in the design and construction of these there are some serious difficulties. These are all due to the low frequency of the machine, which necessitates a large pole-pitch and a high armature reaction. In polyphase generators the armature reaction is practically constant, while in single-phase machines it pulsates. The large pole-pitch, moreover, makes the stress on the end connections of the armature coils more troublesome than is the case of polyphase machines. The pulsating magnetic flux, due to the armature current, gives rise to hysteresis and eddy-current losses throughout the entire magnetic system. It is rather difficult to determine just what these will be, but several methods are suggested which, from experience, have been found to give a good indication of the magnitude of the loss. A satisfactory way is to send current of a normal frequency through the armature and measure the losses by a wattmeter. The exact measurements of the loss are, however, difficult to make. The eddy-current losses, due to the pulsations, may be practically eliminated by laminating the entire magnetic field, but, on the other hand, the use of solid poles gives rise to eddy current which tend to choke back the pulsations and thus reduce the hysteresis loss. If a laminated structure be used, with damping grids of low resistance inserted in the pole-faces, the eddy-current losses in the iron are avoided, while the reaction of the grids reduces the hysteresis loss. The resistance of the grids is small, so that the eddy-current losses taking place in them are not large. In this way the pulsations due to a simple laminated field may be reduced to one-thirtieth of the original value. The use of solid poles would reduce them to half value only. Actual figures for this loss for three machines are given. Without dampers the average loss was three and one-half per cent, but with dampers it was reduced to one-half per cent and the temperature rise reduced from 125 degrees centigrade to thirty degrees. The importance of providing mechanical support for the end turns of sufficient strength is evident when it is considered that a short-circuit on a generator will cause current of fifteen or twenty times normal full-load value to flow. This brings a stress on the coils in proportion to the square of the current, or from 200 to 400 times the normal value. In actual figures these stresses may be from two to ten tons on one end of one armature coil. A satisfactory form of support is shown, this consisting of a heavy girder of bronze.

A paper by Jens Bache-Wiig, entitled "Application of Fractional-Pitch Windings to Alternating-Current Generators," was read, the object of which was to deal briefly with the points leading to the use of a chorded winding for alternating-current generators from the standpoint of manufacture and design and to determine what influence this winding has on the performance of the machine. In general, chorded windings have been adopted to facilitate the manufacture of armature windings, as this enables a standard frame to be used for a number of different ratings at different speeds and voltages. Group windings with a number of slots per pole per phase equal to an integer are generally preferred, and the number of conductors is fixed within a limited range for a given voltage. This often necessitates the use of a chorded winding to get the proper number of effective conductors. An advantage resulting from the chorded winding is the reduced space occupied by the end turns. Moreover, as form-wound coils may be used and space gained, the result is equivalent to taking copper off the end turns and laying it in the slots. This type of winding also reduces the strain on the end turns, making it unnecessary to provide extra insulations there. The demagnetizing effect of the chord winding is practically the same as that of the full pitch winding, and there is also a reduction in magnetic leakage. There is a possibility, however, of currents flowing around the delta of the machine if the electromotive forces of the coils are not pure sine waves. The author concludes that no general rules may be formulated governing the proper arrangement of the chord windings for all cases. Where this is not determined from mechanical reasons, the most efficient chord will depend upon the number of poles, the ratio of pole-pitch to pole-length, the voltage and size of the machine. These must be worked out in each individual case.

The discussion was opened by D. B. Rushmore, who said the greatest difficulty in the construction of large generators is to secure the desired regulation. The mechanical design must always be sufficient to withstand the runaway speed of the turbine, which is a little less than twice the normal. The General Electric Company designs its generators to withstand speeds 100 per cent above the normal. He emphasized the necessity for installing protective apparatus on all large machines.

W. J. Foster pointed out some of the interesting features of the machine described by Mr. Behrend. The armature reaction adapted is unprecedented, which is a good feature. The efficiency is also unusually high. In this machine, nickel steel has been employed, and it is interesting to point out that steel of this class having a high permeability is now available.

A communication from L. Schuler was read by P. H. Thomas, which dealt briefly with the losses in single-phase alternators due to the pulsating armature reaction. He described a method of measuring these losses in which a damper of variable resistance was employed. The use of a low-resistance damper reduces the total loss due to this effect. F. H. Clough criticized the method employed by Mr. Waters of supporting the end coils of his single-phase generator.

Dr. Steinmetz described a method of carrying a single-phase load on a polyphase machine without unbalancing the latter. This consists in placing a reactance coil across one phase and the single-phase load across another. In this way the power loop of the reactive circuit falls behind the two power loops of the load circuit. In other words, power is stored up in the reactance coil during those periods when the external load is not drawing on the generator. In this way it is possible to get a perfectly balanced, uniform load. The arrangement is particularly good for low frequencies.

In closing the discussion, Mr. Waters criticized rather sharply the generator described by Mr. Behrend, saying that in the design it appeared to him mechanically weak. In regard to Dr. Steinmetz's suggested method of balancing the load, he said it was all a question of cost, and the single-phase generator might be the cheaper.

The two remaining papers on the schedule for the morning session were then presented.

J. R. Bibbins, in a paper entitled "Double-Deck Steam Turbine Power Plants," described in some detail the equipment of the West Point station. This is one of the new double-deck stations in which the generating machinery is placed above the boilers on the second floor of the station. Some of the important features of this design are the supporting of the generating apparatus entirely by the steel building skeleton and the carrying of a water-cooled floor column through the middle of a boiler setting to reduce weight and cost of the beams spanning the battery. This arrangement simplifies all the piping and produces a compact, accessible and efficient plant. It is estimated that the total cost of the station, excluding property and siding, was $563,520. As the station has an output of 8,500 kilowatts, this gives a cost of $66.25 per kilowatt.

In concluding his abstract, Mr. Bibbins said that credit for the success of this type of plant must be given to the two engineers, Dr. Louis Duncan and Thomas Elliott, who had designed and built the Fort Wayne station.

J. R. Bibbins, in a paper entitled "Working Results from Gas-Electric Power Plant," gave a report of a thirty-day test on the service plant of the Richmond works of the American Locomotive Boiler Company, of Richmond, Va. This plant contains a horizontal gas engine driving a generator rated at 325 kilowatts. The test showed that the pounds of coal per kilowatt-hour at full load were 1.65. The thermal efficiency, from coal to electricity, at the same load was 14.35 per cent. From the figure obtained at the plant an estimate is given of the cost of installation and operation of a 700-kilowatt gas-engine plant as compared with an equivalent steam-turbine plant. The equipment cost of the first was found to be $96,600, while the fixed charges would be $12,220. This should produce one kilowatt-hour, at full load, for 1.62 pounds of coal. The steam-turbine plant would cost $70,000 to install, the fixed charges would be $8,050 and the coal consumption at full load would be 2.96 pounds per kilowatt-hour. The cost per kilowatt at the gas plant would, therefore, be a little less than one cent, with coal at $1 a ton, and about one and one-half cents with coal at $6. With coal at $1 a ton the steam-turbine plant would save eight and one-half cents over the gas-engine plant; at $2 a ton the two would be about equal; and at $6 a ton the gas-engine plant would save nineteen per cent.

The discussion was opened by C. W. Ricker, who has been associated with the West Point plant and who gave some interesting figures showing the distribution of cost. Assuming as a basis a rating of 3,000 kilowatts, the following cost table was submitted, the figures being the cost per kilowatt:

Building and all cement work........	$21.40
Boiler plant, settings, pump, pipe and pipe covering..........	14.24
Barometric condensers............... ...	6.41
Generating plant.......................	37.59
General supervision of erection..........	2.42
Making a total of..........	$82.06

J. P. Jackson discussed briefly the interesting features of Mr. Bibbins's two papers, and laid much stress upon the necessity for entire reliability.

The session was then adjourned.

WEDNESDAY AFTERNOON SESSION.

The sixth session of the convention was called to order Wednesday afternoon, July 1, about 2.30 o'clock, by Vice-President Armstrong, and four papers pertaining to electric railways were read and discussed.

Dr. J. B. Whitehead, Jr., in a paper entitled "From Steam to Electricity on a Single-Track Road," gave a somewhat detailed analysis of the equipment which has been decided upon for electrifying a single-track steam railroad known as the Annapolis Short Line, connecting Annapolis with Baltimore, Md. This is a single-track road of standard gauge, twenty-five and one-quarter miles in length, with a four-mile extension beyond Annapolis to Bay Ridge, a summer resort on Chesapeake Bay. The Baltimore terminal is in Camden station, the main terminal of the Baltimore & Ohio Railroad. The maximum gradient on this road is one and one-half per cent, of which there is one stretch a mile and one-half long. The severest curves are one of eight degrees and one of six degrees. The present normal service is seven trains a day, making an approximate monthly car mileage of 30,000. The reasons for the change from steam to electricity are to increase the traffic by providing a better train schedule and in this way build up the local traffic and the excursion business. Through traffic between the two cities is not likely to change much, but the section through which the road runs offers many opportunities for suburban homes which are much more likely to be built if served by an electric road. It is not thought that the change will reduce the cost of operation, but profit is expected as a result of other changes. Power will probably be purchased from one of the large modern plants in Baltimore, of which there are two, both having power arrangements with the Susquehanna development. The car selected has seats for sixty-two passengers and is fifty-five feet long. The body weighs about sixteen tons. By using the multiple-unit control trains may be built up of these cars. The system decided upon is one of twenty-five-cycle, single-phase, alternating-current, which has been selected after a comparison with the 600-volt direct-current system. The author goes into considerable detail over the predetermination of the voltage drop in conductors and rails, and in the considerations which led to the selection of the motor equipment. One-hundred-horse-power motors were chosen, four of each being placed on each car. The form of this equipment is compared with that of a similar equipment of ninety-horse-power direct-current motors, and it is shown that in spite of the greater weight of the alternating-current equipment, the average energy consumption of the latter is only 3.2 kilowatt-hours per car-mile, as compared with 3.32 kilowatt-hours per car-mile for the direct-current system. The saving is due to the reduction of rheostatic losses through the use of a transformer in starting. Dr. Whitehead computes that the cost of the alternating-current equipment will be $344,300, including the overhead system, nine cars, power-house and substation apparatus. An equivalent direct-current system would cost $397,300. The cost of operating the electric system is estimated to be 28.47 cents per car-mile, an increase of 5.37 cents over the present figure for steam operation. The author concludes that from a general consideration of all the factors entering into the problem, the electrification will prove profitable.

The discussion was opened by W. I. Slichter, who pointed out the advantages of the high-potential, direct-current railway system for such conditions as those described by Mr. Whitehead. This system is being developed by the General Electric Company.

William McClellan said that in choosing a system to be adopted on any section of road, the engineer should look far enough ahead and select that system which is not merely the most suitable for the particular conditions obtaining on the first section to be electrified, but which will be the most suitable for the electrification of the entire road. We are apt to-day to overestimate the influence of local conditions and to select an equipment to meet them only, without taking into account those conditions which must be met as the electrical zone is extended further and further.

A. H. Babcock referred briefly to the conditions existing on the section of the Southern Pacific Road, the electrification of which is now being contemplated. He said that the first estimates of the cost of equipment with a direct-current system and a single-phase system agreed with one another within the liability of error, hence the selection of the system will turn upon the cost of operation and not that of equipment. He wanted to know what the engineers should recommend under such conditions if they could not obtain entirely reliable information on the costs of operating the two systems. He asked Mr. Whitehead whether the observed drop of potential in the overhead line and track agreed with those which had been calculated.

A communication from A. W. Copley was read, which gave the results of measurements of the impedance of the track return of the New Haven system. Current measurements have shown that the percentage of current returning through the rail varied from twenty-five to forty and that returning through the earth from seventy-five to sixty per cent. The rail impedance at twenty-five cycles is from two and a half to three times the rail resistance. These figures show that the track furnishes a better return for the alternating current than had been assumed when the system was laid out.

Replying to Mr. Babcock's question, Dr. Whitehead said that there had been no opportunity to check the voltage drop on the road which he had described so as to compare it with that calculated, but it had been found that the starting conditions of the cars were very good.

A paper on "Induction Motors for Multi-Speed Service, with Particular Reference to Cascade Operation" was presented by H. C. Specht. This discusses the various methods employed for varying the speed of induction motors. Each of these involves certain disadvantages which have precluded the general adoption of any one of them for all purposes. The most generally employed method is that of inserting resistance in the secondary circuit. This is open to the objection that the speed of the motor then varies with the load. For small motors this method is satisfactory, but for large motors intended to be used at two or three different speeds and giving good efficiency and good regulation it is not suitable. To meet the requirements of such cases independent motors may be used having different numbers of poles, the rotaries of which are mounted on the same shaft; or a single motor with separate windings, each of which gives a different number of poles; or a single winding may be employed, but split up so that it will give a different number of poles; or the secondary of an induction motor may be connected to a synchronous motor; or, finally, two induction motors may be connected either in direct or differential concatenation. This last arrangement gives, in general, four speeds—that of each motor used singly and that produced by each method of combining them. Equations for these combinations are then deduced and discussed and the curves illustrating them are plotted. The practical advantages of the combination are set forth, these being the fairly good efficiency and power-factor procurable, the latitude in design of the motor, the flexibility and simplicity of the speed control and the safety of operation. To illustrate the method, consider two motors, one running at 720 revolutions a minute and the other at 1,200 revolutions a minute; these two speeds are available. Direct concatenation will give 450 revolutions a minute, and differential concatenation 1,800 revolutions a minute; and, if desirable, intermediate speeds may be secured by connecting resistance across the circuit connecting the motors.

Mr. Slichter asked what is the effect upon the performance of the motor of varying the number of poles.

A. E. Averett said that when a change of speed is made by changing the number of poles, the efficiency of the motor is held up, but the power-factor goes down. One-half the problem is in the mechanical design of the motors. If a close range to the normal speed of operation is desired, concatenation works well, but for variations from the normal speeds the arrangement is not good.

A. E. Sperry asked whether the concatenated system as described made practicable the return of energy to the line.

In closing, Mr. Specht said that two motors would develop less torque than a single motor because of the double losses taking place. He then described briefly certain combinations of induction motors which had been proposed by Heyland and others, which he said were good when it was desired to start up a small input.

G. B. Werner read a paper on "The Determination of the Economic Location of Substations in Electric Railways." Of the considerations that govern the layout of the secondary distribution of electric railways, the question of economy is generally preponderant, but the theoretical economic solution may be difficult or impossible of attainment on account of certain operating considerations which may dictate a cross-section of secondary copper other than that indicated by Kelvin's law. For instance, it is necessary that the cars be able to move under the most unfavorable conditions irrespective of the question of economical drop. There may also be important commercial considerations which influence the location of a substation. The author develops an equation involving the number of substations, or the distance between substations, which will render the total annual charges on the installation a minimum. This equation is in terms of the various constants fixed by the length of line, the time-table, weight of the cars, motor characteristics, cost of energy, and equipment charges. There are a number of annual charges which are independent of the number of substations, such as those due to the trolley suspension and to the high-tension distributing system when a separate line is not run to each substation. Algebraic expressions are developed for the annual charges on substations, the annual charges on overhead copper influenced by the station location, the annual cost of substation losses and the annual cost of secondary conductor losses. The author points out that the track losses may generally be neglected because they are relatively small and, when brought in, result in an equation of the third degree. His final equation shows that for a minimum value of the annual charges the cost of copper is equal to that part of the cost of the substations which is independent of the output. The method of applying this solution is demonstrated by an example and the author concludes that his method obviates the usual necessity of solution by trial. By substituting in his equation constants already available from previous technical and commercial study of the service requirements of any road, the economical distance between adjacent substations is at once determined.

S. B. Fortenbaugh read a paper entitled "Conductor Rail Measurements," which consisted of a discussion of measurements of rail insulation which have been made on the Metropolitan District Railway and the Baker Street & Waterloo Railway, both of London. There are fifty-six miles of main-line double track and three deep level "tube" railways, aggregating about twenty-eight miles of double track. Third and fourth conductor rails were installed on the above lines, supported on brown stoneware insulators. In 1905 considerable trouble was experienced in maintaining the insulation resistance of the negative conductor rail, so that an extended investigation was undertaken to account for the trouble. The results obtained were rather erratic. While the voltage between the positive rail and the ground remained approximately 500, that between the negative and the ground was seldom as high as 100, and at times was as low as forty or fifty. Reversing the polarity of the two rails reversed the phenomenon after forty-eight hours; bringing the negative conductor again nearly to the potential of the earth brought back the original condition. The following conclusions are drawn: The difference of potential between the positive conductor and earth is normally considerably greater than the potential existing between the negative conductor and earth. This difference is the more marked the longer the conductors are subjected continuously to a difference of potential in the same direction, and reversal of the polarity is instantly accompanied by a considerable increase in the normal leakage current between the positive and negative conductors. The insulation of the negative conductor to earth can not be proportionately maintained. It is suggested that these results depend upon the phenomena long known in connection with static charges; that is to say, that a negative charge leaks away much more quickly than does a positive charge. A negatively electrified conductor appears to be discharging negative ions, which have the effect of conferring conductivity on the surrounding gas and causing deposition of moisture from air more or less saturated. It seems probable that this same action might render the insulators of the negative rail more or less conductive, due possibly to a film of liquid which gradually spreads out from the conductor over the surface of the insulator. It is possible, also, that the reducing chemical action of the ions may result in the formation of compounds which actually lower the resistance of the negative insulator.

C. J. Hopkins, in opening the discussion, questioned the usefulness of Mr. Werner's formula for the location of substations. He said that too many assumptions must be made when applying it, and, after all, local conditions which can not be allowed for are most likely to settle the question. The problem is thus a practical one, and can hardly be helped by such analytical studies.

Mr. Werner said that he realized fully the difficulties of applying analytical solutions to such problems, but the ordinary method of trial and failure is so laborious that any means of lightening it should be acceptable. Of course, in the actual application of his method, local considerations are very likely to shift the location somewhat.

P. M. Lincoln said that when such a solution as proposed by Mr. Werner was employed, the final location must be adjusted afterward so as to fit all conditions.

P. H. Thomas said that although the method might not give the final solution for all conditions, it is a good plan to make some such general analysis of these complex problems.

(To be concluded.)

Electricity in Churches.

The use of electricity in churches is not large, it is not continuous, so that it would not be feasible to install an isolated plant. To take advantage of the convenience of electricity, however, many churches have been wired for electric current. The main consumption of electricity in churches takes place on Sundays and holidays only. Since they have no plant of their own they are obliged to draw on the local plants for supply. The greater bulk is used for lighting purposes, the remaining portion being used to operate fans, ventilating systems, chime mechanism and for supplying the organ with air.

The accompanying illustrations show what has been done in the harmonious design of candelabra, clusters and brackets. Although not originally designed for electricity, the old-style gas fixtures can be modified for the use of the electric current. It will be noticed in Fig. 1, showing the interior of Cross Church, Dresden, that all the candelabra were originally designed for gas, but have been fitted with electric fixtures. In Fig. 2 is shown the interior of St. Juergens Church, in Kiel, demonstrating the application of tantalum lamps. Owing to the characteristics of this lamp, the individual lamps have been placed farther apart; little use is made of larger clusters. The application of group lighting, such as candelabra, is shown in Fig. 3.

FIG. 1.—INTERIOR OF CROSS CHURCH, DRESDEN, GERMANY.

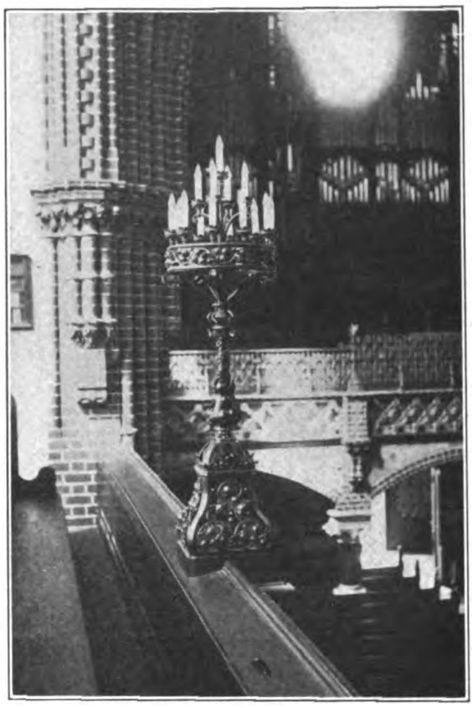

FIG. 3.—INCANDESCENT LIGHTING ADAPTED TO CANDELABRA.

In connection with the lighting of a church it is essential that the wires be concealed and run in approved duct. In the above-mentioned churches the Peschel system of conduit, as used by the Siemen-Schuckert Company, is installed.

FIG. 2.—INTERIOR OF ST. JUERGENS CHURCH, KIEL, GERMANY.

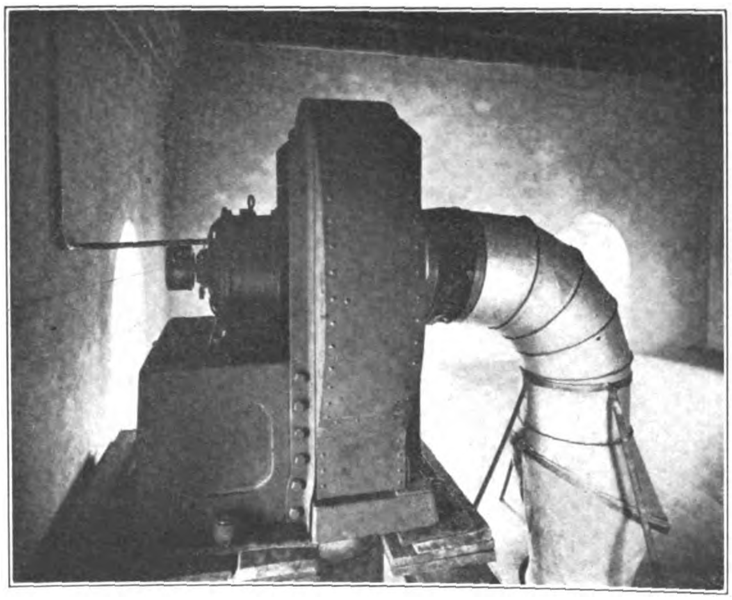

FIG. 4.—MOTOR-DRIVEN FAN FOR SUPPLYING AIR TO ORGAN IN CHURCH AT POTSDAM, GERMANY.

In Figs. 4 and 5 is illustrated the application of the electric current to an organ. Fig. 4 shows the motor-operated fan. The motor is of five horse-power, making 1,400 revolutions per minute. It will readily be noticed that the fan can be placed in any available space. The rheostat for operating the motor is placed conveniently near the organist's stool.

FIG. 5.—RHEOSTAT AT SIDE OF KEYBOARD OF ORGAN IN A CHURCH AT KIEL, GERMANY.

In Fig. 6 is given an excellent illustration of the application of an electric motor. As shown, a six-horse-power motor drives the chime-ringing device of a church in Potsdam, Germany.

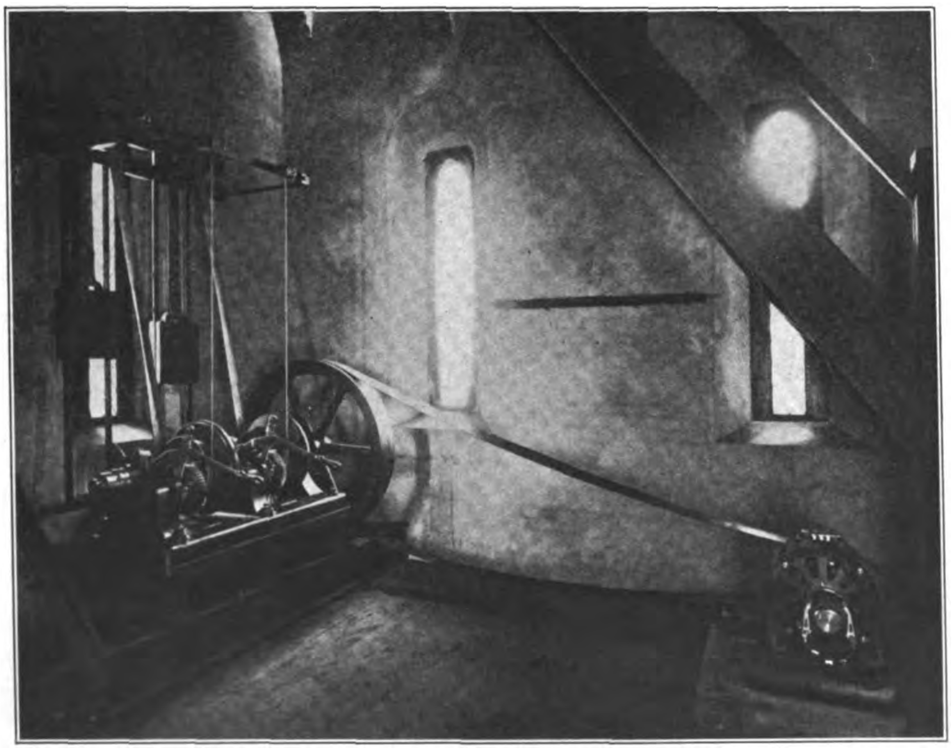

FIG 6.—MOTOR-DRIVEN CHIME-RINGING DEVICE IN A CHURCH AT POTSDAM, GERMANY.

Another very ingenious application of electric motors is their use in winding up the weights of tower clocks; motors of one-tenth horse-power being of sufficient size for the purpose.

The Faraday Society.

The thirty-seventh ordinary meeting of the Faraday Society was held on Tuesday, June 9, at the Institution of Electrical Engineers, 92 Victoria street, London, England, Dr. F. Mollwo Perkin, treasurer, in the chair.

Dr. Albert Frank read a paper, "On the Utilization of Atmospheric Nitrogen in the Production of Calcium Cyanamide, and Its Use in Agriculture and Chemistry."

The practical manufacture of calcium carbide in the electric furnace in 1894 by Willson and Moissan furnished Professor Frank and Dr. Caro with the ideal base required for fixing atmospheric nitrogen in the place of the metallic base which they had previously used (barium) in their experimental search for a commercial method of producing cyanide of potassium for the recovery of gold in mining. As a result of these researches the Cyanid Gesellschaft was founded, which has supplied such a large proportion of the cyanides used in gold extraction in South Africa, Australia and the United States. They also led to the production of calcium cyanamide (nitrolim), a genuine substitute for sulphate of ammonia and nitrate of soda for all agricultural purposes, and which can be produced in unlimited quantities wherever limestone, coal and air are available, containing up to twenty-eight per cent of nitrogen.

The only other practical method of fixing atmospheric nitrogen which has been perfected of recent years for similar uses to calcium cyanamide, is known as lime saltpetre, and has been invented by Professor Birkeland, of Christiania, but this process, though successful from the scientific point of view, requires considerably more expenditure of power than the Frank-Caro process, and the product possesses, for agricultural purposes, several drawbacks which calcium cyanamide does not. The latter has been so long and extensively tried by agricultural experts all over the world that its behavior is no longer doubtful. It can replace for all purposes sulphate of ammonia and for most purposes nitrate of soda, with the added advantage which neither of the others possesses of being alkaline instead of acid. It does not require any greater precautions in application than the other nitrogenous manures, and can with certain precautions become a useful constituent of mixed or complete manures, as has been determined by Dr. Hall's Rothamstead investigations. It is not so subject to being washed out of the upper soil by heavy rains as either of its predecessors and its effect is more persistent. The lecturer illustrated this part of his lecture with lantern slides of the relative results of the nitrogenous manures, including cyanamide, on a variety of crops—wheat, barley, oats, mangels, beets, etc., all showing at least equality with the older and better known manures.

Calcium cyanamide by melting with certain fluxes yields pure cyanide of potassium or sodium, and in the form of "surrogate," which can readily be produced near most gold mines, is an efficient substitute for cyanide in the recovery of the precious metals. Ammonia can also be readily and inexpensively obtained from it. Concentrated into dicyandiamide, it is in increasing demand for the manufacture of organic dyes, and its future as a "deterrent" in the form of salts of guanadine to reduce the temperature of explosion in high explosives and prolong commensurately the life of the inner tube of big guns, is assured; it also does away with the flash accompanying explosion as well as with smoke. Mixed as a powder with other ingredients, calcium cyanamide tempers, hardens and cements steel in the most efficient way.

The author then proceeded to describe the practical features of the manufacture of nitrolim. The carbide is first ground to powder in air-tight mills, filled into furnaces which are kept full of nitrogen, and raised to and maintained at a temperature of 800 degrees to 1,000 degrees centigrade for several hours, then allowed to cool slowly, and finally reground into a fine slate-black powder, which is sent out to the farmer in paper-lined bags, containing from fifty-seven to sixty-three per cent of pure cyanamide, or twenty to twenty-two per cent of nitrogen, with about twenty per cent quicklime, fourteen per cent of carbon, and seven to eight per cent of silex iron oxide and alumina. To replace the present consumption of Chili nitrate by calcium cyanamide would require something like 800,000 horse-power, and works are springing up all over the world to produce it wherever water power is abundant and cheap. The first works established for producing and selling 3,000 to 4,000 tons a year, working for the last three years, were in Italy, at Piano d'Orte (Abruzzi), and are now being enlarged for an output of 10,000 tons. Another works is just being erected at San Marcel (Val d'Aosta) for another 4,000 tons, and the great Terni Carbide Works are laying themselves out for the production of some 10,000 tons in the near future. Dalmatia has followed the Italian example at Sebenico, at Fiume (each for an initial 4,000 tons), and at Almissa, where 50,000 horse-power is available, and a further 10,000 tons output is being planned, all the product being required in the Balkans, Hungary and the Mediterranean coast of Africa, and Egypt.

France already possesses two works for an initial output of 4,000 tons; Switzerland, one for 3,750 tons; Germany, three works with an initial output of 12,500 tons, and one in prospect in the Bavarian Alps for 15,000 tons. The United States Cyanamide Company is erecting a 5,000 to 6,000-ton works at Ontario, in Canada, to begin with, and another to follow in Tennessee of much larger proportions. The central provinces of India are to be supplied from works on the Nerbuddah River, while the Japanese are erecting a works at the southern end of Kuiskzu Island for an initial 4,000 tons. The largest works, however, are due to British enterprise and have just been completed at Odda, in Norway, for an initial output of 12,500 tons, with facilities for a prospective increase to 50,000. At the Odda works the largest Linde plant for obtaining nitrogen from the air ever designed has been erected. These works are supplied with carbide from the adjacent works of the well-known Alby United Carbide Factories Company, with an initial capacity of 34,000 tons, which can be readily expanded to four times that amount by calling further on the available water power at command, up to 80,000 horse-power. Slides illustrating the features of the several works mentioned were thrown on to the screen.

The author concluded by stating that by the end of the present year works for the production of 45,000 tons of nitrolim would be in full swing, but this would not sensibly affect the market for sulphate ammonia and nitrate of soda as the demand for nitrogenous manures and products was increasing so rapidly, by over 15,000 tons of nitrogen a year in Germany alone. Both agriculture and the arts and industries seemed capable of absorbing untold quantities of nitrogen in ever-increasing amounts and there were no signs of surfeit.

Henry Cottrell pointed out that a great advantage of these artificial nitrogenous manures is that they are all alkaline, whereas the native nitrates are acid and produce in time sickness in the soil. It was difficult to persuade the farmer, however, to use new manures.

Walter Reid, referring to some tests he had made on calcium cyanamide, drew attention to the moisture in the soil as having considerable effect on the results of such tests. With regard to the use of calcium cyanamide in smokeless powder, he had found it rather too efficient in slowing the explosion.

Dr. H. Borns hoped the author would furnish some fuller details regarding the efficiency and construction of the electric furnaces in which combination of nitrogen with carbide took place.

Dr. J. H. Voelcker said farmers could not be expected to use new manures until they were perfectly satisfied as to their cost and effect. There were, for example, at present certain disadvantages connected with the use of nitrolim which would have to be eliminated before it could become entirely satisfactory. Beyond that the situation was determined entirely by price.

W. Murray Morrison asked whether the cyanamide could not be made direct from limestone and coal in one operation.

J. L. F. Vogel asked what fear there was of a charge of carbide not being completely nitrated.

The chairman drew attention to the use of cyanamide in synthesis, and hoped that some of the very interesting and important compounds that could be made from it would be manufactured in this country.

Dr. Frank replied to the points raised by the various speakers. Cyanamide was ten per cent cheaper than ammonium sulphate. Its stability was good; although the lime absorbed moisture, there was no loss of nitrogen. Up to the present its manufacture in one operation had not proved successful.

At the meeting of the society held on June 23 a paper was read by J. Härdén entitled "Recent Developments of the Kjellin and Röchling-Rodenhauser Electric Induction Furnaces." Adolphe Jouve communicated a paper entitled "New Applications of Electrometallurgical Alloys."

The following officers were elected to serve for the ensuing year:

President, Sir Oliver Lodge.

Vice-presidents, G. T. Beilby, R. A. Hadfield, Professor W. Hittorf, Professor A. K. Huntington, Lord Rayleigh, Professor A. Schuster, Professor J. J. Thomson.

Treasurer, F. Mollwo Perkin.

Council, Bertram Blount, A. C. Claudet, S. Z. de Ferranti, F. W. Harbord, R. S. Hutton, T. M. Lowry, H. F. K. Picard, James Swinburne, J. F. L. Vogel, N. T. M. Wilsmore.

New British Patent Law.

The representations made by the United States and Germany asking an extension of the time limit beyond August 28, when the new British patent law is to go into effect, have proved unavailing. This law provides that foreigners who obtain British patents must manufacture the patented goods on British soil. President of the Board of Trade Churchill definitely informed the House of Commons on July 2 in this connection that the government had no intention of proposing fresh legislation to modify the sections of this law to which foreign patentees have taken objection.

The Use of Automobile Trucks by the Pennsylvania Railroad Company.

The Pennsylvania Railroad Company, as an experiment, has introduced the use of automobiles to expedite the handling of freight between stations in large cities. Such a service has been started between Kensington and Shackamaxon stations in Philedalphia, Pa., and if it is a success it is planned to try the same experiment in other large terminal cities, such as Pittsburg and Baltimore.

The automobile truck which the Pennsylvania Railroad is using in Philadelphia has saved between six and twelve hours in the handling of package freight between the stations named. This freight automobile has a capacity of five tons and is driven by a six-horse-power electric motor. It averages about seven and one-half trips a day, carrying 2.2 tons per trip; its daily mileage averaging about eight miles.

Previous to the introduction of the automobile in the Kensington district, small lots of freight were sent from station to station in cars. With the automobile service congestions are relieved and the movement of freight by a direct route instead of a circuitous one saves both time in delivery and the use of freight cars.

The Pennsylvania Railroad is also bringing the automobile into use in its passenger service. In Jersey City an innovation is the introduction of large automobile trucks in the baggage service. These trucks are about the size of a three-horse wagon and are so built that, when loaded, the floor of a truck is on a level with and flush against that of a baggage car.

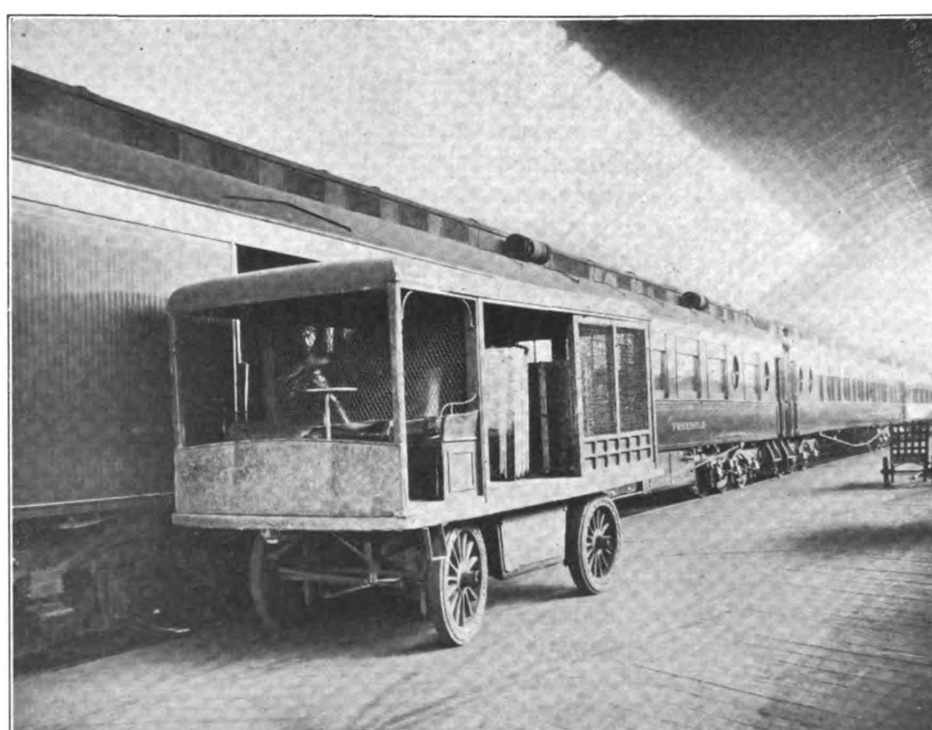
Many hard knocks are in this way saved to every trunk handled through the Jersey City station. In moving a trunk from the car to the truck it receives about the same handling it would get in being shifted about inside the same car. This is but one of the trunk-protective features of the trucks. Another is that they are enclosed entirely with a wire grating and leather top, preventing any scraping or falling in the trip across the river.

The service to which the new trucks are being put entails through trips between the baggage cars and the Twenty-third street station, in New York. They are loaded to their full capacity and are raised and lowered between the ferry level on elevators. The electric power does away with the manual labor formerly necessary to push loaded trucks up the heavy grades at the approach to the ferries, at certain stages of the tide.

The truck is about fifteen feet long and five feet wide, with a seat in front for the driver. Its height of about nine feet is necessary that the floor of the truck may meet the baggage-car floor on a level.

So satisfactory have these automobiles proved in the baggage and mail service that there are now being built a number of small electric trucks for use in the new terminal station in Washington, D. C. These will be similar to the trucks now used in Broad street station, though they will embody improvements which are expected to overcome the slight difficulties experienced with the first automobile trucks that were placed in service.

Automobile Freight Truck Used for Hauling Freight Between Local Freight Stations of the Pennsylvania Railroad in Philadelphia, Pa.



Large Automobile Truck Used by the Pennsylvania Railroad in Transferring Baggage from Cars in the Jersey City Terminal to New York City.

A DIRECTIVE SYSTEM OF WIRELESS TELEGRAPHY.

To the Editor of the Electrical Review:

In your issue of May 9, Mr. O. C. Roos reviews the two articles describing the system of directive wireless telegraphy published by us in *Electrical Engineering* (November 14, 1907 and March 5, 1908).

Mr. Roos characterizes our account as being "interesting, but in some respects indefinite"; that is to say, that our explanation lacked clearness in certain parts, as would also appear from the observations made by Mr. Roos.

We intend now to clear up certain obscure points. The diagrams of the energy emitted or received by an aerial of our system were obtained by the employment of the thermogalvanometer, which responds to the whole of the energy received and not to the maximum amplitude of the oscillations; and only in applying the detectors generally employed (electrolytic, magnetic, coherer, etc.) to our system were we obliged to make reservations as to the diagrams to be considered in the different cases in relation to the special manner in which these detectors operate.

In the description of the transmitting radiogoniometer we said that the primary winding induces in the two aerial circuits currents whose intensity and phase vary with the orientation of the said winding.

To make this point more clear, which we evidently did not sufficiently explain previously, let us consider the case of a single secondary winding connected to a single *closed oscillatory circuit* forming the aerial. When the plane of the primary winding coincides with that of the secondary, the current induced has its maximum value. On turning the primary bobbin through 180 degrees, the current in the aerial will have the same value as before, that is to say, will be a maximum, but its phase will be altered by half a period with reference to the phase of the former current. In other words, when one causes the movable coil to pass from one side to the other of the axis of the fixed winding, the phase of the current changes by a half period while at the same time its intensity passes through zero.

For the radiogoniometer with two secondary windings the phenomena are the same. No special relation exists between the length of wave used and the dimensions of the aerials, for obtaining the phase difference. The radiation from a closed oscillatory circuit is due to the electric field of dispersion, the lines of force from which extend from the armatures of the condenser to the earth's surface; and since at the same instant these lines of force are on the one side of the opposite sign to those on the other side, it follows that the phase of the magnetic field in the one sense differs by one half period from the field in the opposite sense.

When the aerial is formed of two vertical closed oscillatory circuits mutually perpendicular, the space can be regarded as being divided up into four quadrants. The partial fields set up by the two circuits will be in phase in two opposite quadrants and in consequence they add themselves; in the two remaining quadrants they will be opposite in phase and hence they are to be subtracted. If one varies the phase in one of the aerial circuits by one half period, by suitably turning the movable winding, in the two quadrants where previously the fields were in phase they will now be in opposition of phase, and *vice versa;* the direction of the maximum radiation will have passed from one pair to the other pair of quadrants.

Mr. Roos asks with what exactitude the determination of azimuths can be effected with our system when the station is encircled by disturbing influences such as adjacent buildings, ships and other stations, and what accuracy we obtained in our determinations of the bearings of the Channel stations.

To this we can reply that every time it was possible to take a sufficient number of observations of the bearing of known transmitter stations the approximation was always close to about one degree; and in the most unfavorable case, where the signals lasted only a few seconds, it was easy to get within five degrees. In the extreme case, where a station might be so surrounded by buildings that the waves arrived distorted or deviated, it would be possible to find empirically the relation connecting the true bearing with the apparent bearing as given by the radiogoniometer.

As regards the disturbing effects of other transmissions, the only station which affected the directive reception at Havre was the station at Dieppe belonging to the Western Railway of France, which is situated in the same plane with reference to Havre as our own station at Dieppe; and the wave-length employed at this station is nearly the same as at our station, while the energy employed and the damping are both very much greater. Other disturbances arose from the signals from ships inside the harbor at Havre at a distance of only a few hundred metres from our station.

The coupling between the aerials and the exciting circuits has always been loose, which is an inherent condition with closed oscillatory circuits having too great a self-inductance to permit of close coupling being employed.

E. Bellini and A. Tosi.

[The foregoing letter from Messrs. Bellini and Tosi was translated by L. H. Walter, who translated for *Electrical Engineering* the two articles above referred to, and upon which the criticism from Mr. Roos was based.]

Electricity in the Mines and Reduction Works of the Anaconda Copper Mining Company.

In the issue of the *Mining and Scientific Press* of June 27, a very interesting report of the operation of the mines and reduction works of the Anaconda Copper Mining Company is given. Electric locomotives have been installed on several important levels of the Anaconda group and are giving satisfactory results in efficiency and cost of haulage. The new compressor building erected at the Diamond mine contains four electrically driven compressors with a total capacity of 16,000 cubic feet. These are all fitted with steam cylinders for use in case of failure of the electric current. Four new 600-horsepower, alternating-current electric motors and two circulating pumps and four five-ton traveling cranes have been installed.

The Never Sweat compressor plant now consists of five compressors with a capacity of 32,000 cubic feet of air per minute, two of the largest being electrically driven.

Since February, 1907, electric power has been used at the concentrator and in other departments of the works. This power has been found efficient and the cost much below that of steam for the same work. A large part of the electric power furnished at the works is brought from the Missouri River, but during the year the Flint Creek water power and electric light plant has been furnishing a considerable amount of current.

The Washoe company installed in its substation at the works three 400-kilowatt transformers, one voltage regulator for the city lighting system, and additional switchboard capacity for the new blast-furnace blower-house. In the smelter power-house there have been installed one 600-horse-power motor, one 750-horse-power motor for blowing engines, and one 600-horse-power motor for an air compressor. An entirely new blower building has been erected, with a fifteen-ton crane for handling machinery, four 600-horse-power motors, and four blowers, each of 36,000 cubic feet of air per minute capacity.

REVIEWS OF CURRENT ENGINEERING AND SCIENTIFIC LITERATURE

The Influence of Humidity Upon the Electrical Discharge from Points in Air.

An investigation of the effect of moisture upon the electrical discharge points in air has been made by John Zeleny. It is of some importance to establish the magnitude of this effect so that the results of experiments performed on different days in the open air may be directly compared, and so that laboratory results for dry air may be applied to such cases as the discharge from points of lightning conductors or the discharge from high-potential wires. The experiments were designed to determine the influence of humidity upon both the voltage required to start a discharge and the magnitude of the potentials required to produce different currents. The apparatus consisted of a brass wire about a quarter of a millimetre in diameter and four centimetres long. The end was rounded and placed at a distance of one and one-half centimetres from a brass disc seven and one-half centimetres in diameter. The two were enclosed in a brass cylindrical vessel fifteen centimetres high and thirteen centimetres in diameter. The disc was connected to earth through a galvanometer and a telephone, and the point could be maintained at any desired potential by means of a small Wimshurst machine. Air was passed through the apparatus and then through a gas meter. The amount of water contained was determined by measuring the absorption in calcium chloride tubes. The experiments were conducted at various temperatures, and the first important fact noticed was that the effect of water vapor depends upon the absolute water content of the air, and not on its relative humidity. Evidence on this point was obtained by observing the discharge with dry air and then air saturated with water vapor at three degrees centigrade. It was found that the ratio of potential required to obtain a given current in air at this low temperature was smaller than when the air was at the ordinary room temperature, and this ratio for the cold air corresponded in both discharges to that obtained for warm air having equal water content. Two sets of curves are given, the first showing the influence of humidity upon the positive discharge in air. The curve showing the point at which the positive discharge begins is nearly horizontal, the amount of water vapor having but little effect, though apparently with a tendency to diminish the critical potential. The other curves, which show the potential required to maintain different values of current, show that this increases with the humidity of the air, and the increase is somewhat more rapid for the dryer air. From these curves it is possible to plot a second set showing how the current produced by a given potential changes with the amount of water vapor present. The curves showing the effect of humidity upon the negative discharge in air are somewhat more erratic than those for the positive discharge. That showing the potential at which the discharge begins lies below that for the positive critical value, as do all the curves for corresponding currents. The form of these curves corresponds, however, to those for the positive discharge, and the potential required to produce a given current increases with the amount of water vapor in the air, the change being more rapid when the amount of water present is small. The total increase from dry air to saturated air is about sixteen per cent.—*Abstracted from the Physical Review (Lancaster), June.*

The Design of a Continuously Adjustable Resistance.

A certain investigation making necessary a resistance which would vary continuously the current through a coil from a maximum value in one direction to a corresponding value in the other, a study of the problem thus presented was made by J. T. Morris, R. M. Ellis and F. Strude. The results of their investigation are given here. A liquid resistance was first tried, and the type first experimented with consisted of a cast-iron tank containing a soda solution, into which an electrode could be gradually lowered, finally short-circuiting the whole of the resistance. As the short-circuiting occasioned an abrupt change in the current, it became necessary to work with a lower resistance of the electrolyte. This could not be accomplished sufficiently well by the use of soda nor by copper sulphate; consequently, dilute sulphuric acid was tried. A direct consequence of the decrease of resistance now became apparent in an abrupt change of the current immediately the electrode entered the liquid. This effect might have been diminished by using an electrode with a finer point, but the method was abandoned because it permitted a variation in current from the maximum value to zero only, and it was desired to obtain a complete reversal in one operation. For this purpose a liquid resistance was tried. This was in the form of a trough with current passing continuously through it. By means of two movable lead electrodes attached to a shifting belt, so that they would travel simultaneously, a continuous variation in current from the maximum positive to the maximum negative value was obtained; but there was difficulty in obtaining sufficiently large final values with a soda solution, so that sulphuric acid was substituted. The latter, however, gave rise to polarization, causing an abrupt reversal of the current as the electrodes passed one another. A better arrangement was obtained by using two large water resistances, but the device was neither portable nor efficient. An attempt was then made to substitute resistances built up of carbon plates, which could be pressed together more or less firmly. Two such resistances were used, each divided into two portions by insulating plates connected in a way similar to the arms of a Wheatstone bridge. This method was inefficient, and the resistance of the arrangement was uncertain, unless the plates were pressed firmly together. Next a similar arrangement built up of wire was tried, the wire in the first design being wound on a piece of slate. Contact was made by means of two sliders to reverse the screws rotated by a common hand wheel. This arrangement was satisfactory for currents not greater than one ampere, but when larger currents were employed, the adjustment, as the sliders approached one another, became less and less continuous. The arrangement was rather bulky and noisy in operation. It was therefore discarded for a resistance consisting of a single strip of metal folded up in zigzag form, the alternate portions being insulated from one another by mica. The strip was one and one-quarter inches wide and 0.005 inch thick. The total number of folds was

2,000, and two sliders were provided, which are traversed over the same side of the resistance by means of screws. This arrangement answered the purpose admirably. The only objection to it is the time required to shift the sliders so as to produce considerable variations in the current. There is one defect of little importance, which is the slight break in the continuity of changes produced by the short-circuiting of adjacent layers of the resistance by the two brushes as they pass. —*Abstracted from the Electrician (London), June* 26.

Converting Hand-Blown Organs.

Several simple methods of adapting an electric motor to driving hand-blown organs are here described by J. W. Barr. All of these methods have been actually applied by the author. Where a rocking lever is still retained the problem is somewhat troublesome and generally necessitates the installation of a crank-shaft. In one case an organ which required the services of three men was converted to the electric drive by connecting three rocking shafts to a crank-shaft having three cranks, and on which was a thirty-six-inch pulley which was belted to the motor pulley. To control the motor a liquid resistance was placed in the armature circuit, and the electrode suspended from a cord attached to the wind chest. As the latter rises as it is filled with air, the electrode is gradually lifted out, decreasing the speed of the motor. At first there was some difficulty due to pulsations of the motor as the circuit was made and broken when the amount of air drawn from the wind chest was small. In this organ there were two wind chests for furnishing air at different pressures. By connecting the regulator to both chests the operation became smooth. The crank-shaft was driven at thirty-two revolutions a minute. The motor required five amperes at eighty volts. About 350 watts were dissipated in the liquid resistance. The motor pulley was about six inches in diameter, and the speed, when reduced by the resistance, was 200 revolutions a minute. This motor runs within four feet of the organist's seat, and the regulator is placed just back of the organ. The operation is entirely noiseless, and all that is required to maintain the system in good condition is an addition of soda solution once a week to make up for evaporation. Blowing this organ by hand cost $50 a year. To drive it electrically costs about $1.10 a month, with energy at four cents a kilowatt-hour. A second organ which the author transformed to the electric drive had but a single wind chest. The hand-blowing arrangement was a thirty-inch wheel fitted with a handle rotating a three-throw crank-shaft. A leather belt was placed over this wheel and over a motor pulley, and a liquid resistance installed, as in the first case, although here the electrode was counterbalanced so that in case the controlling string should break, the motor circuit would be opened. The author does not think that the induction motor can be used as satisfactorily for organ blowing on account of the disagreeable magnetic hum. He, however, installed a single-phase, five-horse-power induction motor for operating a large organ, belting the motor to the crank-shaft as in the cases just described. In this case it is necessary to install a belt-shifting device for throwing the load off and on the motor, and a damper in the feeder to the wind chest which controls the amount of air supplied to the latter. The running performance was not altogether satisfactory.—*Abstracted from the Electrical Review (London), June* 26.

The Electric Train-Lighting System of the Gesellschaft für Zugbeleuchtung.

The system of train lighting here described is being introduced in Germany, and makes use of the Rosenberg dynamo. This machine, it will be remembered, delivers a fairly constant current independently of the speed at which it is driven. The regulation is secured by short-circuiting the usual brushes and by placing a pair of secondary brushes midway under the poles. The latter brushes furnish the series exciting current, and the charging current for the batteries. The armature reaction produced by the currents flowing through the short-circuited connection not only maintains the output current constant, but maintains unchanged its direction when the direction of rotation is changed. When this system is employed a number of auxiliary devices are necessary, and these are described here in some detail. Two types of generator are constructed, one intended to be placed in the baggage car, where it is more or less under control of the train attendants, and the other for suspension under the cars. The dynamos are completely encased, as is also the driving belt, which is provided with a stretcher. Roller bearings are used, which require but slight attention. There are two methods of applying the system, one employing two batteries which are alternately charged and used, and the other, which is less expensive, uses but a single battery. In the latter case automatic means must be provided for preventing the battery when charged from discharging through the generator. On the Prussian State Railways movable switches are prohibited. In their place an electrolytic valve cell is used. There are two electrodes, consisting, respectively, of aluminum and iron, placed in a solution of ammonium borate. In operation the solution liberates ammonia, which is undesirable, but sodium and potassium can not be used. It is necessary to have the aluminum electrode completely covered by the electrolyte. A rubber-covered lead is attached to it, the lug itself being covered with rubber and vulcanized on the plate. These plates must be formed before assembling, which is done by thoroughly cleaning them and then maintaining them subjected to a potential for several days while in the borate solution. The cells are intended to resist potentials of forty volts. Some of them have been in use for six years without giving trouble. To regulate the potential at the lamps fine iron wire resistances similar to the Potter ballast employed in the Nernst lamp are used. The company has also developed automatic switches, which are installed when preferred to the electrolytic valve. When the latter is used it is necessary to replenish the electrolyte every four days or so in summer, and in winter about every ten days. A fifty-ampere cell weighs complete about eighty-eight pounds.—*Abstracted from Engineering (London), June* 26.

Municipal Lighting at Manchester, England.

The report of the Electricity Committee of Manchester, England, for the year ended March 31 states that on the year's working there was a net surplus of $97,715, of which $9,965 has been appropriated for extension of works (for which borrowing powers can not be obtained), $50,000 has been paid to the city fund in aid of rates, and the balance, $37,725, has been carried to the reserve fund. The total income was $1,923,010. The working expenditure absorbed $1,096,790, and the balance was $826,220. The reserve fund now stands at $69,270. The capital outlay up to the end of the year amounted to $12,212,995. At the end of December prices of current for lighting purposes were reduced from nine cents to 7.25 cents per unit to consumers on the flat rate. To long-hour consumers the reduction was from $35 per kilowatt of maximum demand and 3.5 cents per unit to $35 per kilowatt of maximum demand and three cents per unit.

The total output of electricity from the three generating stations during the twelve months amounted to 82,752,989 units, as compared with 63,056,914 units of the previous year, an increase of 31.24 per cent. The total mileage of main conductors laid on March 1, 1908, equals 338 miles 1,084 yards, being sixteen miles 1,001 yards more than on March 31, 1907.

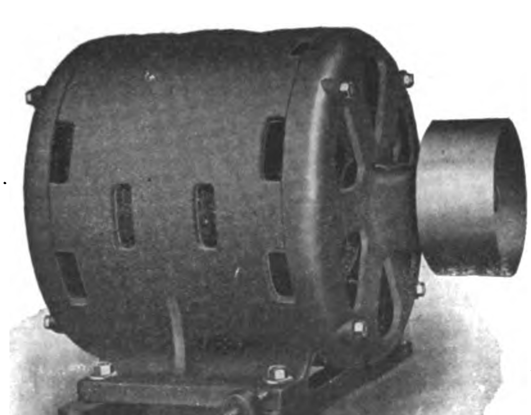
INDUSTRIAL SECTION

ILLUSTRATED DESCRIPTIONS OF NEW AND STANDARD ELECTRICAL AND MECHANICAL APPARATUS

IN the last issue of the ELECTRICAL REVIEW considerable space was given to descriptions and illustrations of electrical apparatus which entered largely into the work of the electrical contractor. The apparatus described and illustrated in the following pages is also of especial interest to the contractor and in many instances is shown for the first time.

The Richmond Electric Company's Polyphase Induction Motor.

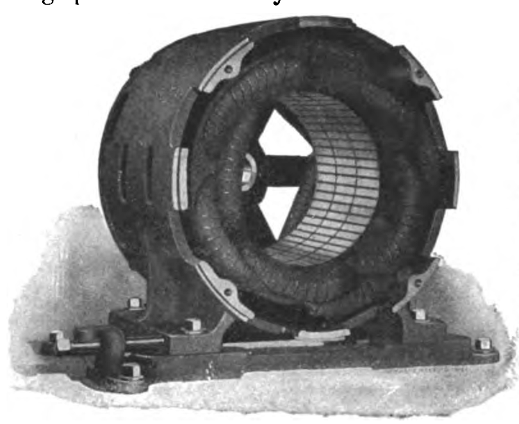
The Richmond Electric Company, Richmond, Va., has placed on the market a polyphase induction motor, illustrations of which are shown herewith. Great care has been taken to make these motors compact, light, free from vibration, and at the same time having the highest possible efficiency and power-factor. The company is now manufacturing these machines of the squirrel-cage type in sizes from one-quarter to fifty horse-power. The stator frames are of cast iron in one piece. The feet are broad, and the entire frame construction is such that there can be no possible springing, and a rigid support for the laminations is secured.



RICHMOND POLYPHASE INDUCTION MOTOR.

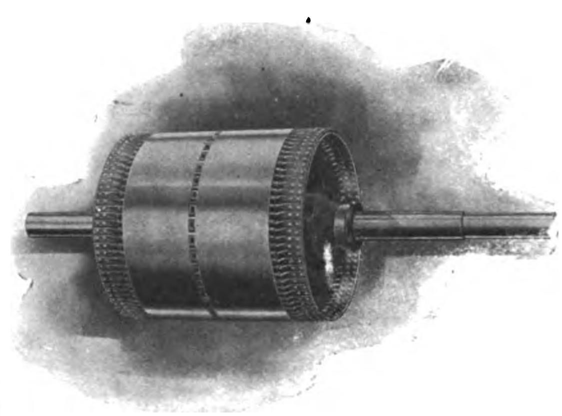
The stator windings are liberally designed for carrying capacity, and sufficient insulation has been used to withstand severe service and avoid breakdowns.

The rotor is built up of thin discs of sheet steel, clamped under hydraulic pressure. These rotors are of the squirrel-cage type, the heavy insulated copper bars being placed in entirely closed slots and



STATOR OF RICHMOND POLYPHASE INDUCTON MOTOR.

riveted to resistance rings at each end. Before winding, the outside diameter of



ROTOR OF THE RICHMOND POLYPHASE INDUCTION MOTOR.

the rotor and the inside diameter of the stator are ground to exact diameters, presenting a bright, smooth surface and insuring an absolutely accurate air-gap.

A special starting winding is placed in the stator slots of these machines. This winding, at the time of starting, is thrown in series with the running coils, and after the machine has been brought up to speed these coils are cut out of circuit with a double-throw switch provided by the company.

Machines smaller than seven and one-half horse-power are not usually furnished with starting coils, but are thrown directly upon the line with an ordinary single-throw switch.

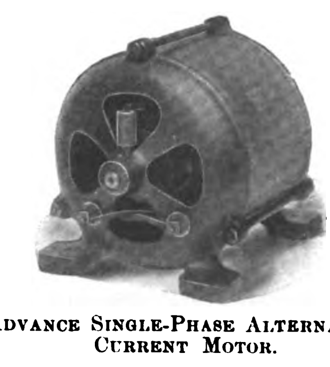
The Advance Electric Company's Single-Phase, Alternating-Current Motor.

The accompanying illustration shows the one-quarter-horse-power, single-phase, alternating-current motor placed on the market by the Advance Electric Company, St. Louis, Mo. This is an induction motor with the field of the usual construction, slotted, laminated and coil-wound, and connected directly to the supply circuit. The induced currents in the armature are carried by two sets of conductors. One set, near the surface of the core, is an insulated winding connected to a commutator which is short-circuited through a set of brushes; and the other set is deep down in the core and consists of copper bars extending through a circle of holes and securely connected to the conducting flanges connecting the armature discs.

The mechanical construction follows the best modern practice, with large steel shafts and ample bronze bearings. The lubrication on the smaller sizes is by grease cups, and on the larger sizes by oil chambers and oil rings.

The motors may be arranged for wall or ceiling suspension, and can be supplied at extra cost with enclosing covers, special shafts, back gears or idler pulleys. The motor is started by simply closing the switch, and may be stopped or started from any distance.

The motor is reversed from the outside without changing connections, by loosen-

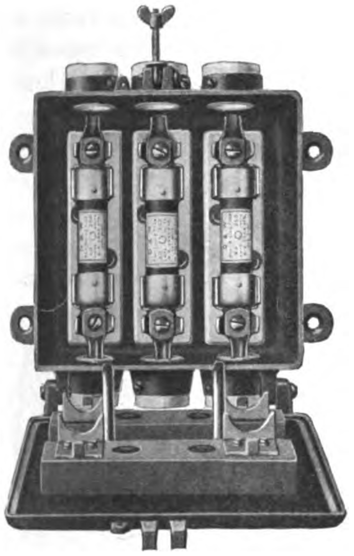


ADVANCE SINGLE-PHASE ALTERNATING-CURRENT MOTOR.

ing a clamp stud and turning the field to an index mark for the opposite direction of rotation. The motor may be operated at any speed below normal by reducing the voltage by either a rheostat or transformer.

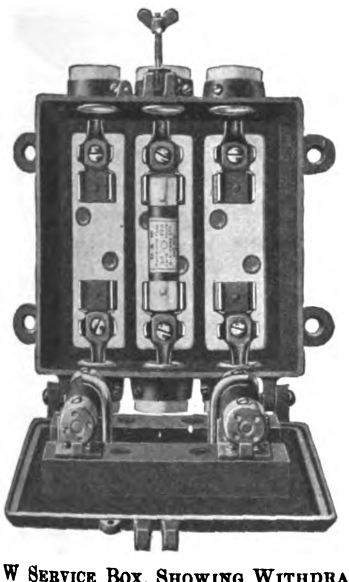
Recent Improvements In Weatherproof Service Switches and Branch Boxes.

There has developed, within the last few years, a large demand for weatherproof service switches, and they have been



New D & W Weatherproof Service Box.

extensively used with the result that severe conditions have indicated ways in which they could be improved. One of the weaknesses of the old-style switch was that the neutral fuse was removed when the switch was opened, which sometimes resulted in accidents owing to the fact that the removal of the fuse opened the



D & W Service Box, Showing Withdrawal Hooks on Positive and Negative Only.

ground connection of the neutral wire. Another point was that while the old-style box was intended as a weatherproof box, not being provided with gaskets, it frequently fell far short of meeting this requirement.

A new line of D & W switches and boxes has been developed in which these defects have been corrected. They are constructed for use both as cutout and switch, and are intended to be placed on the outside of buildings where overhead wires enter, or in cellars where the wires enter from the subway. The accompanying illustrations show how the service switches are so designed that the neutral fuse remains permanently in the box, thus avoiding any possibility of accidents due to the fuse being improperly withdrawn. Withdrawal hooks are provided on the positive and negative only. This avoids any possibility of tampering with the box through ignorance or otherwise, and in case of fire the neutral fuse is drawn, leaving the other fuses in the box.

Fuse guides are mounted in the covers to accurately align the fuses, so that positive contact is made when the cover is again closed, throwing the fuses into circuit. There are also mounted in the covers withdrawal hooks, which, by a one-quarter turn of the levers on the outside of the cover, remove the positive or negative fuse at will, and, when desired, the cover can also be opened without removing any of the fuses. The fuses are of the well-known D & W National Electrical Code standard, and the boxes are provided with rubber gaskets and removable porcelain bushings, thus making them thoroughly moisture-proof when the cables are taped in. The outlets of the box are amply large, so that after the bushing is removed the cable terminals may be passed through the box and sweated on to the cable, which is highly desirable during installation.

To insure a uniform product, the castings are made in the factory's own foundry and are of much finer grade than are ordinarily purchasd in the open market, being lighter in weight as well as having a smoother, finer finish.

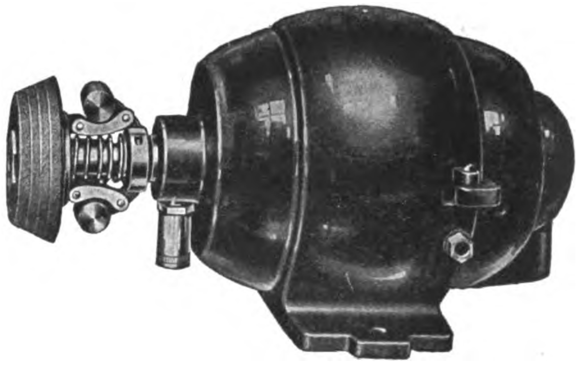
Branch boxes and main-line boxes are manufactured in the types and capacities given below: Type I-7, 0-60 amperes, double-pole; type I, 0-60 amperes, triple-pole; type I-8, 61-100 amperes, double-pole; type I-2, 61-100 amperes, triple-pole; type I-9, 101-200 amperes, double-pole; type I-3, 101-200 amperes, triple-pole; type I-10, 201-400 amperes, double-pole; type I-4, 201-400 amperes, triple-pole; JB-1, thirty amperes, triple-pole, single-branch, 250-volt cutout boxes; JB-2, fifty amperes, triple-pole, single-branch, 250-volt cutout boxes; JB-3, 100 amperes, triple-pole, single-branch, 250-volt cutout boxes.

Branch boxes have split bushings mounted in the covers and boxes, which permit of the necessary connections without any break in the wiring, thereby reducing the cost of installation.

This improved line of cutout boxes is being placed on the market by the Central Electric Company, Chicago, Ill.

Apple Ignition Apparatus.

Although not strictly to be considered as part of an electrical installation, as these terms are generally understood, contractors are finding a very profitable



Apple Dynamo.

field in applying ignition apparatus and in selling ignition supplies for use with gas engines and in the automoble industry.

The Dayton Electrical Manufacturing Company, Dayton, Ohio, has developed an ignition apparatus consisting of an Apple

Apple Snap Switch and Ampere Meter.

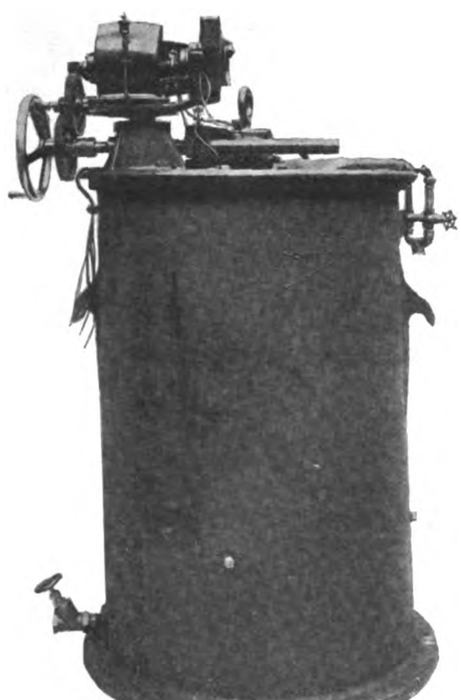
dynamo, a switchboard and a six-volt, sixty-ampere-hour storage battery.

The plan of wiring this outfit provides for taking the ignition current from the storage battery at all times, while the dynamo is used simply to keep the battery recharged. The switchboard acts as a terminal for all wires between the dynamo and the battery, and by means of the meter on the switchboard the operator can ascertain at all times just how much current he has available.

The outfit has two reliable sources of current—the battery and the dynamo. The current should be taken regularly from the battery while the dynamo keeps the battery recharged, but in an emergency the dynamo can be used without the battery.

Westinghouse Potential Regulators.

In order to secure good regulation throughout a central station distribution system means must be provided for regulating the voltage on each feeder. The voltage drop in any feeder depends upon its arrangement, sectional area and length, and upon the amount and power-factor of the load it carries. The time-load curve of each feeder must also be considered in comparing the voltage drops on several feeders, as it is evident that these curves may vary widely, even when the average loads on the feeders are approximately the



WESTINGHOUSE POLYPHASE MOTOR-OPERATED INDUCTION REGULATOR.

same. By compensating for the voltage drop on each feeder independently of all the others, good regulation can be established with widely varying conditions of load. It is for this purpose that the potential regulators described herewith were primarily designed.

The Westinghouse Electric and Manufacturing Company, Pittsburg, Pa., makes regulators of different kinds for varying the potentials on feeder circuits. The two principal types employed are the induction type potential regulator and the step-by-step type potential regulator. The first type effects the regulation of a single-phase circuit by altering the position of a coil in a magnetic field, thereby changing the magnetic flux passing through the coil; the second type by cutting in or out, by means of different taps, sections of the winding of a regulating transformer. Both of these types of regulators are made for either single-phase or polyphase circuits. The single-phase regulators are generally used on feeder circuits supplying electric lights, and the polyphase regulators are used in connection with rotary converters on feeder circuits supplying power either with or without lights.

The design of the Westinghouse potential regulators is such that a minimum amount of material enters into their construction, leading to light weight and compactness, and requiring minimum floor space. Leads from two similar coils are brought out through the case. These can be connected in parallel outside the case, so that double the rate of current can be regulated through half the standard range. A further advantage of the induction type regulator is that it lends itself readily to automatic operation, so that a constant potential may be maintained on the feeder circuit without attention on the part of the station operator.

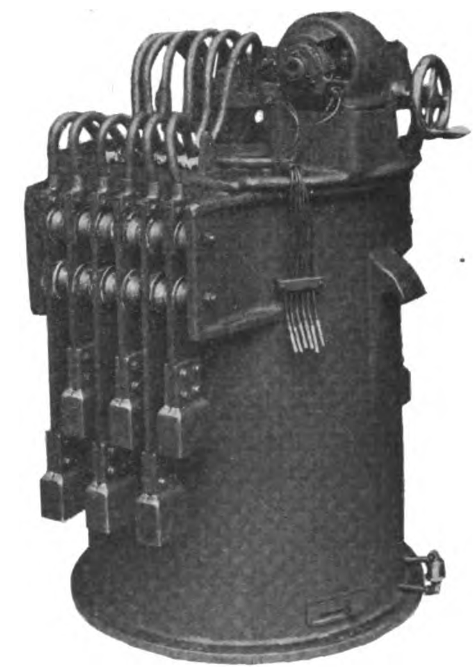
The capacity of the regulator for any given service depends on the range of regulation required and the total load on the feeder. The standard regulators are designed to raise the voltage ten per cent or lower the voltage ten per cent, thus giving ten per cent regulation; and the capacity, therefore, would be ten per cent of the full load of the feeder. For example, a 100-kilowatt circuit with ten per cent regulation would require a ten-kilowatt regulator. If five per cent regulation were required a five-kilowatt regulator would be necessary.

The essential parts of a single-phase induction regulator are a rotatable primary core and windings assembled on a shaft, and a stationary core with windings which is mounted in the regulator case. The rotor is operated by means of a worm wheel and worm, the shaft of the latter being driven either by a hand wheel or by a motor through spur gearing. The cases of both the manually operated and the motor-driven induction regulators are the same, and are made of cast iron well ribbed so as to provide ample cooling surface. The top of the case, which forms the cover, is a separate casting held in place on an accurately machined surface by means of four poles. A hole is bored in the centre of the cover, forming the upper bearing of the primary or rotor shaft.

The rotor shaft is revolved by means of a bronze worm wheel which engages a forged steel worm, the latter being provided with a ball bearing end thrust. The housing for the worm gear is a separate casting which is bolted to the cover. This casting is made separate instead of being an integral part of the cover, in order to permit close adjustment between the worm wheel and the worm.

On the automatic regulators the worm shaft is connected to the motor through a spur gear and pinion. This makes a compact driving device. A handle is also provided on the automatic regulator so that in case of emergency the regulators may be operated manually. When hand-operated regulators are furnished the spur gear is replaced by a hand wheel, and the regulator is driven directly from the worm shaft.

In motor-driven induction regulators the operation of the motors is controlled



SIX-PHASE AIR-BLAST INDUCTION REGULATOR, MOTOR-OPERATED, FOR USE WITH SIX-PHASE ROTARY CONVERTER.

by means of relays. As the current-carrying capacity of the contacts or switches for starting, stopping and reversing the motor must be ample, entailing substantial construction, and as the accuracy of regulation must be approximately from one-half to one per cent under all conditions, it has been found desirable to divide these functions between two relays, one the voltage-regulating relay and the second the auxiliary relay.

The voltage-regulating relay is in effect a contact-making voltmeter which is connected to the circuit to be regulated. Its functions are to close one contact when the voltage of the circuit is below the desired value, and to close another contact when the voltage exceeds the desired value. The relay is mounted in a circular case of the same general appearance as those of the Westinghouse indicating switchboard meters. The total energy required for this coil is about ten watts at normal voltage.

The secondary or auxiliary relay is connected between the voltage relay and the motor circuit, and is designed to relieve the contacts of the primary relay from carrying the whole current required to operate the motor. The auxiliary relay is in effect an electrically operated, double-pole, double-throw switch with carbon contacts. It is so connected as to start the motor in either direction and at the same time release the motor brake. These relays vary slightly in design according to the character of the service and the ampere capacity required. They may be wound to suit the voltage and the frequency of the auxiliary circuit used.

The principle of the operation of the step-by-step potential regulator is practically the same as that of the induction regulator. In the step-by-step type the series coil is divided into a number of sections which may be successively cut in or out of the circuit to be regulated instead of varying the flux through the entire coil as in the induction type. The step-by-step type regulator has been developed in two general mechanical forms—the drum type and the dial type. The former comprises a drum and finger type switch similar to a railway controller, and the latter a face plate with a dial switch for switchboard mounting. The drum type regulator can be placed on the station floor in front of the switchboard or it can be placed behind the switchboard and operated by means of a hand wheel through chains or shaft and gears. It may be mounted in a horizontal, vertical or inverted position as required.

Effective Lighting.

The lighting fixture business in the West has for years been considered a commercial proposition of selling so much metal for its equivalent in money. Most wonderful forms have been created and placed in various buildings without regard to whether such pieces harmonized with the surroundings. The architect, contractor and the consumer have for years visited fixture showrooms contemplating the purchase of lighting effects for their building, whether such building be for public use or for the home, and have been greeted by a maze of metal so dense that it has always caused confusion to the purchaser. After purchasing the desired amount of metal for the building, there still remained a doubt as to whether such pieces as were selected were really appropriate. This condition has caused many disappointments.

For years the Central Electric Company, 264-270 Fifth avenue, Chicago, Ill., has studied the shortcomings of the fixture-supply business in the West, and after looking carefully at all sides of the situation decided that a fixture house which was sufficiently progressive to take a stride forward out of the rut of the past would be appreciated and patronized in a manner which would be profitable. The first step was to acquire a factory equipped for the production of correct and unusual effects in metal. To secure the craftsmen for such an organization it was obliged to locate its factory in Boston, where it now has a designing department, and a factory organization which is second to none in the United States. Each man in this organization has been selected with great care, bearing in mind that to give the public what it desires from the designer of the various effects through to the modeler, the foundryman, the toolmaker and the chaser, there must be in their temperament the necessary feeling for art in its true meaning, and on all of the work produced by this company will be seen in the lines of the model, in the marks of the hammer and the dainty lines forced by the chaser's tools, the characteristics of each individual craftsman.

The following quotation will give some idea of this company's interpretation of the true meaning of the lighting fixture business:

"A lighting fixture must have two inceptions: First, in the designer's thought, made apparent by the use of the pencil, and, second, by craftsmen of sterling worth. It is the service of such an organization that they offer."

In building its studios, the company has given great care to the arrangement of the various rooms so that each fixture is seen individually, and under conditions which enables the purchaser to make intelligent selections. Crowding of the rooms has been avoided, each piece shown being lighted, thus enabling one to see the effect as it will be when the fixture is permanently placed.

The sales organization is composed of representatives having a thorough knowledge of interior architectural detail so that when a prospective client makes known the conditions existing in his building, correct suggestions can be offered. The studios are, undoubtedly, the most complete and beautifully decorated rooms for the display of lighting effects in the West, and every courtesy and convenience is shown prospective clients.

The Central Electric Company cordially extends an invitation to those interested to visit these studios.

A New Strand or Messenger Wire Grip.

As requirements necessitate, the inventive mind is called into play to devise means of supplying something to fill the want. In this particular instance, the requirements were in the nature of a device to handle strand or messenger wire safely, securely and without injury to the wire. For this purpose the grip shown in the illustration herewith has been designed. The grip consists of a body or retaining piece in which two steel wedge-shaped jaws move longitudinally. These jaws are

THE KLEIN "QUICK SAMPSON" WAVE GRIP

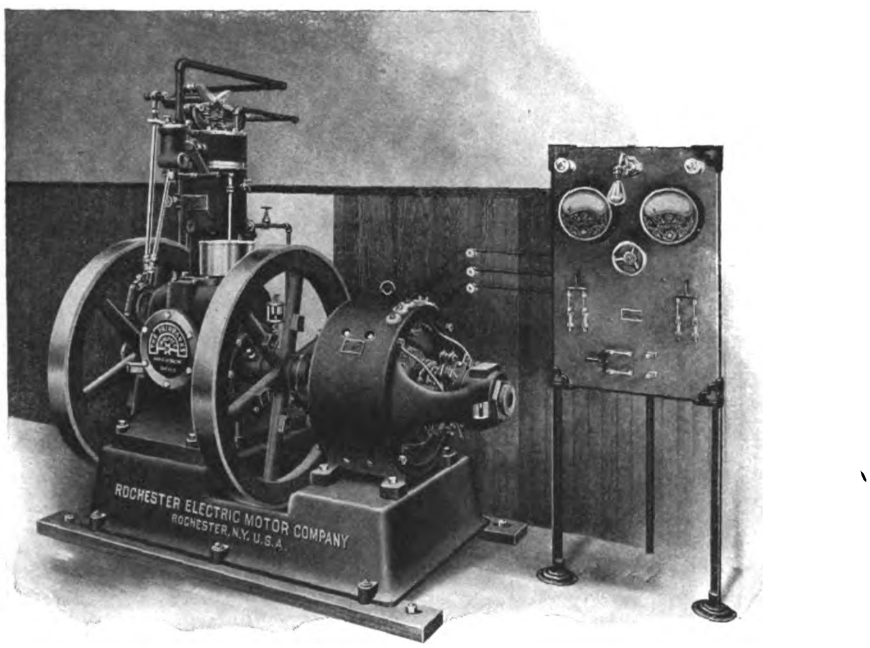
arranged so as to move in either direction simultaneously, thus opening or closing them in unison. The gripping surface of the jaws is concave, and is provided with a series of milled teeth, spread over their entire length. These teeth grip into the spirals of the strand, and being uniformly distributed over the entire length of the jaw, grip the wire at very many points, thus taking a secure hold with the pressure distributed along the entire length of the gripping surface, so that no amount of strain falls sufficiently at one point to crush or injure the wire. The tackle is attached to the two oblong rings in the body piece; these rings, being arranged central, insure a straight pull. The proportions of the various parts are calculated to carry any strain that is necessary to tighten the wire, and the jaws are self-adjusting to accommodate sizes from one-quarter inch to five-eighth inch. This grip is called the "Quick Sampson," and was designed and is manufactured by Mathias Klein & Sons, 87-89 West Van Buren street, Chicago, Ill.

Electric Controller and Supply Company Change of Name.

The Electric Controller and Supply Company, of Cleveland, Ohio, has changed its name to "The Electric Controller and Manufacturing Company." The latter name more truly indicates the nature and scope of its business, as evidenced by the following list of apparatus it manufactures: Controllers, both manual and magnetic switch types for all purposes; lifting magnets, electric brakes, magnetic switches, solenoids, limit stops, arc welders, crane fittings, knife switches, flexible couplings and the electric fault-finder.

The Rochester Motor Company's Gas-Engine-Driven Unit.

The Rochester Electric Motor Company, Rochester, N. Y., is meeting the demands of contractors all over the country for a direct-connected unit of medium size for residence and hotel lighting and for the power equipments of small factories. The accompanying illustration shows a 5.5-kilowatt Rochester type C dynamo direct-connected to a ten-horse-power Fairbanks gas engine.



TEN-HORSE-POWER FAIRBANKS GAS ENGINE DIRECT-CONNECTED TO 5.5 KILOWATT ROCHESTER TYPE C DYNAMO.

For use with ordinary engines the company manufactures a line of generators with a balance or flywheel mounted upon an extension of the shaft. This wheel is of web pattern, turned all over, fitted to a taper bearing, and held in place by both lock nut and key. The bearings are amply heavy to support the balance wheel outboard, and can be easily replaced if necessary. The frame of the dynamo is of a special mixture of cast iron having a high magnetic permeability. In all but the smaller sizes the pole-pieces are built up of punchings of annealed sheet steel. The armature core is built up of carefully annealed discs insulated from each other and mounted directly upon and firmly keyed to the shaft. One-half of the spherical seat is milled from the end plate, the other being an adjustable cone held in place by a lock nut. The commutator is built up of bars of hard-drawn copper insulated with prepared mica, wearing uniformly with the copper. The brushes are of carbon, and no adjustment is needed to compensate for wear or change of load.

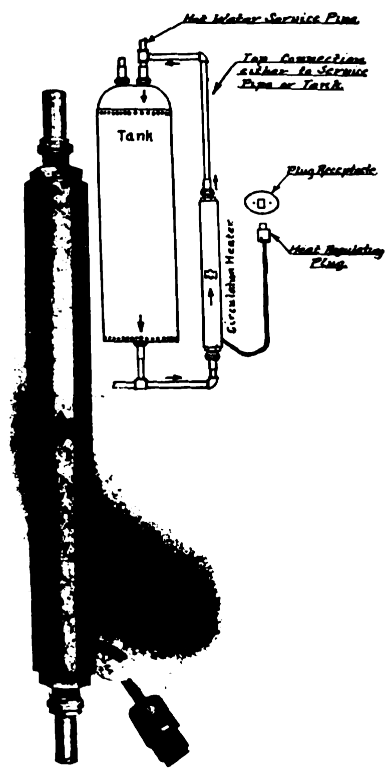
The Simplex Electric Water-Heater.

The Simplex Electric Heating Company, Cambridge, Mass., has recently put on the market a circulation heater for attachment to range boilers which seems to overcome many of the objections and difficulties of taking care of the hot-water problem electrically. As shown in the illustration, the heater is placed along the side of the boiler, connected at the bottom through the pipe that also connects to the range, and at the top with the pipe that supplies hot water to the house. This heater is so constructed that when the current is turned on it will, in a few minutes, begin to discharge water at about 180 degrees into the top of the boiler, drawing its supply from the bottom of the boiler. The maximum power demand for this heater is two kilowatts, and when applied to the boiler in this manner makes the boiler more efficient in the case of quick delivery of warm water than when the range is in operation. The current demand on the station is within reasonable limits, and for all practical purposes meets the average household demands.

The heater is arranged with three heat divisions, so that 500, 1,000 or 2,000 watts may be used as desired. Where considerable hot water is required the maximum heat may be turned on for a limited time and then the temperature of the boiler kept up with the low heat. Where a large quantity is not desired, merely what is needed about the kitchen for ordinary requirements, a short period of the use of the maximum heat enables the supply to be provided at low cost. The efficiency is very high. The heater consists of an enameled tube through which the water passes. Surrounding the tube is an outer brass shell or jacket lined with asbestos, which provides a closed air space between the tube and the jacket.

A peculiar feature of its construction is the control of the circulation, which insures the delivery of high temperature water, thereby permitting hot water to be drawn in a short period after turning on the current while utilizing all present house plumbing in the normal way and yet without having to heat up the entire contents of the boiler.

The use of this device with reasonable control is entirely practicable and commercial in all communities where power rates are made for electric cooking and in many other cases where the convenience and simplicity of the method are allowed to offset the difference in cost over the usual methods. In practice in the ordinary home, even at lighting rates, where care is used the total cost for the use of this heater during such occasional intervals as it may be required in the summer time need never be large, or reach a point which would make its use prohibitive.



SIMPLEX ELECTRIC WATER HEATER.

The installation of the heater involves little work for the plumber and electrician, so that the total cost of the equipment is quite moderate. The device is three inches in diameter, thirty-three inches long, with three-quarters-inch couplings on each end, and when it is connected stands close to the boiler, taking up little room. All of the outer portions are nickel-plated brass. For connecting to the circuit it is provided with a plug switch and flexible conductor.

Automatic Voltage Regulators.

The maintenance of a constant voltage at the lamp not only determines the economy with which a lighting system is operated, but is also essentially the measure by which the customer judges the excel-

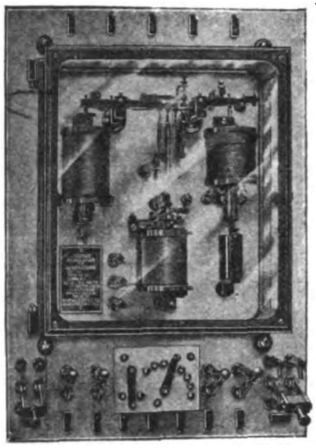


Fig. 1.—Form "A" Voltage Regulator Mounted on Marble Base.

lence of the illumination supplied. The life and candle-power of an incandescent lamp changes rapidly with comparatively small variations from normal voltage and the automatic regulation of voltage at the station so as to give a constant voltage at the lamp is therefore of vital importance and while apparently of benefit

Fig. 2.—Type BR Automatic Regulator.

chiefly to the consumer is in fact of far greater value to the producer.

In order that a practically constant voltage be maintained at the lamp, the generator should be controlled by a potential regulator so as to maintain a constant voltage at the bus or substation independent of load changes. The various feeders branching out from the station should also be controlled by feeder regulators arranged so as to automatically compensate for the drop in that particular feeder due to varying loads.

It is possible to dispense with the regulator controlling the generator by supplying the individual feeders with regulators having a sufficient capacity not only to compensate for line drop, but also to compensate for the voltage variations in the generator. It is, however, advisable both on account of economy and operating conditions to control the generators by a Tirrill regulator. This regulator, shown in Fig. 1, is a relay device mounted on the switchboard and is so adjusted that it controls the generator voltage by rapidly opening and closing a shunt circuit across the field rheostat of the exciter. The action of this regulator is very rapid and there is practically no fluctuation in the voltage. By its use the kilowatt capacity of each regulator for the individual feeders is reduced as well as the number and amount of their adjustments.

Two types of regulators designated as the BR and IR are manufactured by the General Electric Company for automatically controlling the voltage of individual feeders. The feeder regulators of the above types are variable ratio transformers or rather compensators having two separate and distinct windings, primary and secondary, connected respectively across and in series with the feeder to be controlled.

The BR regulator, shown in Fig. 2, consists essentially of a transformer, the secondary of which is divided into a number of equal sections, and a dial switch, the points of which are connected to the sections of the secondary winding. In this type of regulator the moving element is exceedingly light and having but little inertia is particularly adapted for very rapid adjustments. The total time required for obtaining the complete range from maximum boost to maximum lower is about six seconds.

The BR regulator is built only for single-phase circuits and in comparatively small units, since the capacity is limited by the current and voltage which can be conveniently handled by the switch. The capacity of the standard switch is 200 amperes and 220 volts boost and lower.

The induction or IR regulator, shown in Fig. 3, is more rigid, and substantial in construction, and has a less number of moving parts than the switch type and no moving contacts. The efficiency is somewhat higher, but it is slower in operation than the BR regulator as the armature or movable core on which the primary is wound has not only considerable inertia but also a torque depending on the kilowatt capacity, both of which must be overcome by the operating motor.

The three curves shown in Fig. 4 were taken simultaneously and show the com-

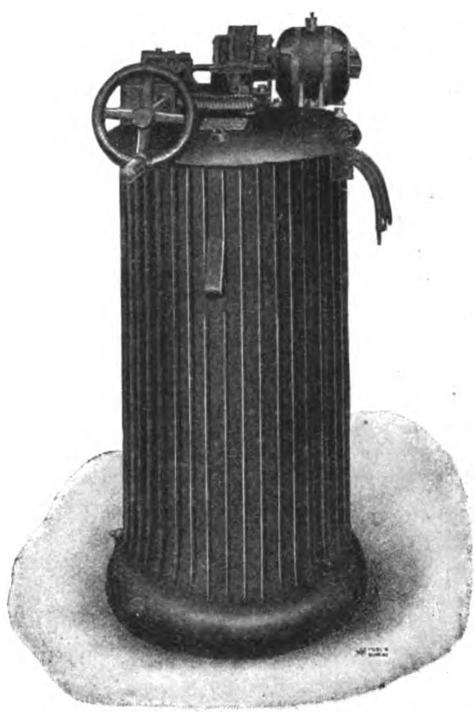

Fig. 3.—Type IR Automatic Regulator.

parative regulation of voltage by General Electric type BR and IR feeder regulators. The middle curve represents the generator voltage, while the upper curve

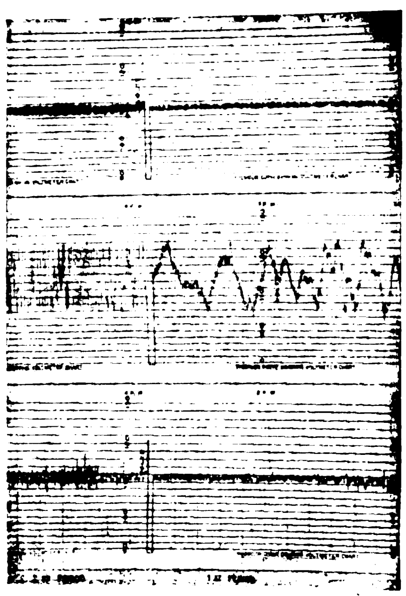

Fig. 4.—Thomson Curve-Drawing Voltmeter Charts, Showing Regulation of Feeder Voltage.

was taken from a feeder controlled by a BR regulator, and the lower curve represents the voltage on a feeder controlled by a regulator of the IR type.

A New Line of High-Efficiency Incandescent Lamps.

The new line of high-efficiency incandescent lamps just brought out by the General Electric Company fills a long-felt want for high-efficiency units of low candle-power. Among the new lamps may be mentioned the twenty-five-watt tantalum, miniature and battery types of tungsten lamps and a complete line of tantalum lamps for train-lighting service in both round and pear-shaped bulbs, made in thirty-fifty-volt and sixty-sixty-five-volt sizes.

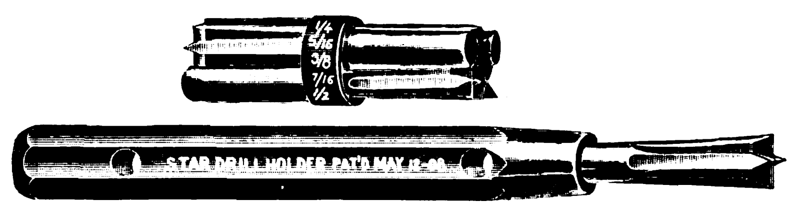
The twenty-five-watt tantalum lamp gives twelve and one-half mean horizontal candle-power. It may be burned in any position and is serviceable on alternating-current circuits of sixty cycles or less. The twenty-five-watt lamp is made in the regular sixteen-candle-power carbon-lamp bulb and presents a more graceful appearance than the tantalum lamps of higher candle-power. This lamp should prove very popular as it consumes but half the current of the ordinary sixteen-candle-power carbon lamp and can be used in conjunction with the tungsten lamp for ordinary socket installations where it might not be desirable to install tungsten lamps on account of their size and higher cost.

The miniature and battery types of tungsten lamps are made in standard and miniature bulbs and can be supplied in any voltage from one and one-half to twenty volts and from fractional candle-powers up to twenty-four candle-power. These lamps are intended for use with electrical novelties, portable devices, pocket lamps, etc., and are particularly applicable for use in automobile service as a substitute for oil and acetylene lamps. The filaments are short, thus insuring good, stable filaments sufficiently strong to withstand the shocks of automobile service. They can be operated from the regular ignition storage batteries very satisfactorily. The efficiency of these lamps is one and one-quarter watts per candle with excellent life and superior quality of light. Tungsten, by reason of the high efficiency it secures, is peculiarly adapted to the battery type of lamps, where low-energy consumption is a prime requisite.

Aside from the miniature and low-voltage lamps the company has also brought out a 250-watt tungsten lamp which is designed for use where the outlets are limited and where a large unit is required to replace present illuminants. The mean horizontal candle-power of the 250-watt lamp is 200, or over 300 candle-power when used as an incandescent unit with a bowl Holophane reflector. The lamp is made in a pear-shaped bulb, five inches in diameter, and is the most powerful incandescent lamp made for lighting service. One of the 250-watt lamps will effectually replace a gas arc or the ordinary electric arc. Recent tests of these lamps in a large department store in Newark, N. J., have shown an average life of 900 hours.

Holder for Drills and Bits.

The Star Expansion Bolt Company, of Bayonne, N. J., has brought out recently an admirable device in the form of an improved holder for electrician's special drills. As will be seen, the holder, while comparatively light, is solid and substantial, enabling a firm hold to be taken and a heavy blow struck, with no danger of breaking even the smallest drill point. Any diameter bit may be had (one-quarter-inch, five-sixteenths-inch, three-eighths-inch, seven-sixteenths-inch one-half-inch) and one size fits in the holder just as readily as another.



Star Drill Holder.

Beyond a large saving in breakage, the Star drill holder possesses another great advantage which will appeal to the man who is in the habit of carrying around a big cumbersome kit with different diameters of drills—all in full twelve-inch lengths. The entire set of Star special drills and the holder itself can be slipped into the pocket, their weight and bulk being scarcely perceptible.

Crocker-Wheeler Company Election.

The following officers of the Crocker-Wheeler Company, manufacturers and electrical engineers, of Ampere, N. J., were elected July 10:

President, S. S. Wheeler.
Vice-president, Gano Dunn.
Second vice-president, A. L. Doremus.
Chief engineer, Gano Dunn.
Secretary, Rodman Gilder.
Treasurer, W. L. Brownell
Assistant secretary, J. B. Milliken.
Assistant treasurer, G. W. Bower.

Westinghouse Electric and Manufacturing Company.

The Merchandise Creditors' Committee of the Westinghouse Electric and Manufacturing Company has issued another circular to the creditors, repeating the figures given out last week relating to its reorganization plan. It reports that ninety-five per cent of all the merchandise creditors have assented to this plan, and that it expects to secure the assent of the major part of the remaining merchandise claims. Substantial progress has been made toward securing from stockholders, employés and others the $6,000,000 of stock subscriptions to assenting stock required by the plan.

With the beginning of July a decided advancement has manifested itself in the business of the Westinghouse companies. It is stated that the business for June was fifteen per cent above that of May, and twenty-three per cent higher than the business of the earlier months of the year. Within the last month it has almost reached its normal point. While the improvement in itself is very encouraging, the character of the orders is of such a diversified nature and the orders have come from so many different sources that they show conclusively the renewed confidence of business men and capitalists. That the revival is not spasmodic is also proved by letters being received from district managers throughout the country.

Long-Distance Telephone Reporting.

The Baltimore *Sun*, in connection with reporting the Democratic National Convention, at Denver, Col., used a 1,800-mile telephone circuit with complete success. A line was formed from Denver to Omaha, to Chicago, to Pittsburg, and then to the long-distance telephone exchange on Belvidere avenue, Baltimore.

Mica Production in 1907.

The total value of the mica produced in the United States in 1907 was $392,111. This is the largest production on record. The imports in 1907 were valued at $925,259.

Current Electrical News

DOMESTIC AND EXPORT.

MORTGAGE FOR $1,000,000 ON GREAT FALLS & OLD DOMINION PROPERTY—The Great Falls & Old Dominion Railroad placed on record on July 9 a mortgage on all its property rights and franchises to secure the payment of an issue of $1,000,000 bonds. The issue comprises 1,000 bonds of the par value of $1,000 each, maturing June 1, 1933, bearing five per cent interest. The mortgage is made to the American Security and Trust Company, of Washington, as trustee. It is understood that under the terms of the mortgage the proceeds from the sale of the bonds may be used to secure acquisitions to the railroad property and to buy other roads. This is the first bond issue of the company.

PHILADELPHIA RAPID TRANSIT $5,000,000 BOND ISSUE—Directors of the Philadelphia Rapid Transit Company have voted to submit the proposition to issue $5,000,000 bonds to stockholders for their approval at the annual meeting September 16. In the meantime no action for the sale of any of the bonds will be taken, as there is no present need of money in addition to that to be received from the assessment payable September 7. In compliance with the regulations of the New York Stock Exchange, where the company's stock is listed, the directors designated a transfer agent and a stock registrar, and arrangements were made for issuing new certificates of stock when the last payment is made in September next.

UNDERGROUND ROAD BETWEEN ST. PAUL AND MINNEAPOLIS—A company, known as the Twin City Underground and Elevated Electric Railway Company, has been organized to build an underground electric railway between Minneapolis and St. Paul. Offices have been established in the Guarantee Loan Building, Minneapolis. The company is capitalized at $50,000 and its officers are: George Norris, president and treasurer; W. E. Stewart, vice-president, and J. W. Crane, treasurer. The estimated cost of the road is $6,000,000. It will be fifteen miles long, and underground trains will make the trip, it is claimed, in twelve minutes. The company says it has opened negotiations with the United States Government for a bridge across the Mississippi River. Officers say they will build a half-way station in the midway district.

MOHAWK POWER COMPANY—The Mohawk Power Company, with principal offices in Glens Falls, N. Y., which is practically a reorganization of the Niskayuna Power Company, and which proposes to develop and sell electricity in several central and northern counties in New York, filed an application on July 1 with the Public Service Commission in the Second District for authority to issue 1,000 shares of its capital stock of the par value of $100. Doubt has arisen as to the right of the old company to transact business and issue bonds, consequently it is proposed to dissolve the old company. Interests in the new company are also connected with the Hudson River Electric Power Company. It is proposed to construct dams across the Mohawk River and its tributaries in the counties of Schenectady, Albany, Saratoga, Montgomery, Herkimer and elsewhere.

TWO-HUNDRED-MILE TROLLEY LINE—An electric railway project that will cover five counties of eastern Oregon has been mapped out by the Wasco County Electric and Power Company. Plans have been made to commence actual construction of a trolley system 200 miles in length during the fall. It is believed by the promoters of the concern that work will be begun not later than August 15. The company was incorporated on May 15, with a number of Portland (Ore.) men in the directorate. Since that time agents have been working to finance the company, and matters have now progressed so far, they say, that a favorable outcome of present negotiations is expected whereby one large syndicate will take the $15,000,000 bond issue authorized by the articles of incorporation. C. D. Charles, financial manager for the Oregon Gold Prospecting and Promoting Company, is promoting the Wasco County Electric and Power Company. His headquarters are at room 318 Marquam Building, Portland. The promotion work is being done under the name of the Oregon Gold Prospecting and Promoting Company, of which Dr. Homer I. Keeney is president and Mark G. Will is vice-president.

REORGANIZATION OF THE UNITED STATES INDEPENDENT TELEPHONE COMPANY PROPERTIES—The reorganization plan of the United States Independent Telephone properties outside of Rochester, as originated by the reorganization committee, is progressing satisfactorily. A large amount of work is being done in Syracuse, N. Y., where a new company, called the Onondaga Independent Telephone Company, is organized to conduct the business under the reorganization. Incorporation of this new company for $1,500,000 was filed with the secretary of state on July 2, with the following named as directors: George R. Fuller, W. Roy McCanne, Joseph W. Taylor and Edward H. Peck, of Rochester, and Alexander H. Cowie, John B. Pierce and Hendrik S. Holden, of Syracuse. The Onondaga company will form an important link in the long-distance chain of the Rochester, Syracuse and Utica systems, which in turn are connected with other long-distance lines. Henry W. Conklin, referee in the foreclosure action of the Security Trust Company, as trustee, against the United States Independent Telephone Company, has filed his report on the distribution of the remaining funds to the non-assenting bondholders. The report shows that the non-assenting bonds amounted to $4,647,000, of which $3,772,000 were proved and $875,000 were not proven. There remained in the hands of the referee, before any deductions were made, $70,527.71, payable to holders of non-assenting bonds. One deduction of $78.50 was made and the remaining amount was increased to $71,198.50 by the interest account. To the holders of the bonds that were proved $58,098.44 was paid, and $13,100.06 is due those not proved. From this amount due bonds of proved ownership $747.27 was deducted for referee's expenses, leaving $57,351.17 as the net balance due the proved bonds, or $15.12 on each such bond.

OBITUARY NOTES.

CAPTAIN THOMAS F. ATTIX, head of the Attix Electrical Engineering Company, of Brooklyn, N. Y., died at his home, 34 St. Mark's avenue, Brooklyn, on July 6, in his seventy-eighth year. He is survived by two sons. Captain Attix fought through the Civil War and in some of the Indian campaigns. He was a member of the Fremont Old Guard and the Montauk Club.

MR. JAMES ROBISON BURNET, a lawyer and president of the Investment Securities Company, died Saturday, July 11, in Roosevelt Hospital, New York city, where he had been operated upon for appendicitis. Mr. Burnet was president of the City Club Realty Company, a director in the Commonwealth Trust Company of Buffalo, vice-president of both the Empire Investment Company and the International Car Wheel Company, president of the Ottawa Water Works and Light Company, vice-president of the United States Land Company and secretary and treasurer of the Publishers' Paper Company.

ELECTRIC RAILWAYS.

BRIDGEPORT, CT. — The Cole's Electric Express Company, which has been doing business in this section for a number of years, has been acquired by the Connecticut Company.

YONKERS, N. Y.—The up-state Public Service Commission has approved of the issuance of $65,000 receiver's certificates by Leslie Sutherland, receiver of the Yonkers Railway Company. The proceeds are for the purchase of fifteen double-truck cars.

NATCHEZ, MISS.—The Southern Railway and Light Company has been incorporated with a capital of $456,700. It is to be the successor to the Southern Light and Traction Company recently purchased at receivers' sale by Lynn H. Dinkins, of New Orleans.

PORTLAND, ORE.—By unanimous vote of the city council on June 24 an ordinance was passed granting to the Mount Hood Railway and Power Company right of way for an electric line across property on the Bull Run Reserve, controlled by the municipality.

YORK, PA.—The York Railway Company on July 1 decided to make four important changes in the road between York and Windsor, which will cost $120,000. They will take out all of the bad grades and curves and establish a solid roadbed with seventy-five-pound steel rails.

FORT WAYNE, IND.—Judge Heaton, of the Superior Court, has authorized J. D. Mortimer, receiver of the Toledo & Chicago interurban road, to purchase new four-motor cars for the line between here and Waterloo. The new rolling stock was much needed. It is to cost not to exceed $22,680.

CHICAGO, ILL.—The Chicago, Lake Shore & South Bend Railway Company, the project of Cleveland capitalists which will gain entrance over the Illinois Central at Kensington, has filed an equipment trust agreement, the Cleveland Trust Company as trustee, to secure an issue of $350,000 equipment bonds.

NEENAH, WIS.—On August 6 the Winnebago Traction Company, operating an interurban line between Neenah, Oshkosh and Omro, will be sold to the highest bidder at auction. The sale is made by virtue of judgment of foreclosure and sale made in the case of the Trust Company of America *vs.* Winnebago Traction Company.

LEXINGTON, KY.—The directors of the Central Kentucky Traction Company, at a meeting on July 2, authorized the building of an interurban line from Lexington to Nicholasville, a distance of twelve miles. The present interurban system extends to Paris, Georgetown, Versailles and Frankfort. The new line will hardly be completed before next spring.

PENDLETON, ORE.—All doubt concerning the Walla Walla Valley Electric Company's intention to extend its interurban line from Milton to Athena has been set at rest with the filing of sixteen right-of-way deeds in the office of the county recorder. The deeds are all across land lying between Milton and Athena, and extend to the heart of the wheat belt. The deeds are all given to two Walla Walla men, E. S. Isaacs and S. M. Drumpeller, and provide that an electric road must be in operation within two years.

ROCHESTER, N. Y.—The Rochester, Corning & Elmira Traction Company applied on July 7 to the Up-State Public Service Commission to modify its order that the entire capital stock must be taken at par before any bonds were issued. The company stated that it has made diligent efforts to comply, but found that by reason of the fact that no part of its road is yet complete or in operation, it is impossible to obtain subscriptions to its entire capital stock at par. The company asks leave to build and put in operation a portion of its line from Rochester and Lakeville to Conesus Lake, twenty-five miles, the cost of which will be $1,277,000, and later to build from Lakeville to Dansville, an additional twenty-five miles, at a cost of $1,705,610. The company asserts that it will be able to construct and put in operation its road from Rochester and Lakeville to Conesus Lake from the proceeds of $1,000,000 and $500,000 stock, and requests authorization for such an issue. The request is made to build a road from Lakeville to Dansville for an issue of $1,250,000 bonds and $750,000 stock at par. It is the intention of the company to operate the first section by purchased power and for the second section it will build a power-house to operate the entire fifty miles proposed. The commission promised to decide the matter at the earliest possible date.

NEW INCORPORATIONS.

HARRISBURG, PA.—Landes Telephone Company, Landesville, $5,000.

CAIRO, ILL.—Home Telephone Company. Capital increased from $5,000 to $10,000.

SPRINGFIELD, ILL.—Industry Telephone Company. Capital increased from $3,000 to $4,000.

MINNEAPOLIS, MINN.—Mesaba Telephone Company. Capital increased from $100,000 to $300,000.

COLUMBUS, OHIO—Delaware Telephone Company, Delaware. Capital increased from $10,000 to $20,000.

GUTHRIE, OKLA.—Starlight Telephone Company, Calumet. $300. Incorporators: George Kennedy, Thomas Jarville and Jeff Pritner.

BOSTON, MASS.—Barnes-Pope Electric Company, Boston. $10,000. President and treasurer, Frank L. Barnes, Waltham; clerk, Herbert A. Pope, Boston.

JEFFERSON CITY, MO.—Lathrop Light, Heat and Power Company, of Lathrop. $5,500. Incorporators: W. C. Young, H. C. Shepherd, S. L. Stuckey and others.

DENVER, COL.—The La Garita Telephone Company, Center, Col. $3,000. Incorporators: C. D. Wadsworth, Michael White, W. E. Gardner, W. F. Bomers and A. W. Dawson.

ALBANY, N. Y.—The Copake Telephone Company, of Copake, Columbia County. $5,000. Directors: Fred Holsapple, of Copake Iron Works; John D. Ackley and Willard Holsapple, of Copake.

NASHVILLE, TENN.—Farmers' Union Telephone Company, of Warren County. $5,000. Incorporators: Robert M. Horton, Aaron B. Moffitt, Alvadore Golloday, Abner D. Womack and Ed Sparkman.

RALEIGH, N. C.—The Little River Power Company. $100,000. To operate a telegraph and telephone line, as well as water, gas and electric plants. Incorporators: M. B. McRae, W. D. McNeill and J. F. Gilmore.

INDIANAPOLIS, IND.—Brookville-Oldenburg Telephone Company, of Brookville. $10,000. Incorporators: I. D. Garrigues, Fred Stumpf, Jr., M. Hubbard, R. S. Taylor, Casper Ritzi, M. Senefeld, F. A. Wright and Herman Trichle.

ST. PAUL, MINN.—Deer River Telephone Company, Deer River. $5,000. Incorporators: Archie McCallum, Deer River; B. L. Freedy, St. Paul; C. D. Rutherford, Floodwood; John E. O'Connell, Deer River; W. Reithner, Deer River.

LAKE CHARLES, LA.—Texas Power Company, Limited, of Houston, Tex. To manufacture, sell and supply gaslight, heat and electric power. $500,000. Directors: Charles A. Cleaver, Charles S. Cleaver, J. A. Reed and Rufus Cage.

RICHMOND, VA.—Mount Olive & Saint Luke Telephone Company, Mount Olive. $6,000. George A. Copp, president, Strasburg, Va.; J. G. Sager, vice-president, Woodstock, Va.; Josiah Wisman, secretary and treasurer, Woodstock, Va.

DUBUQUE, IOWA—Dubuque & Delaware County Telephone Company, Dyersville. $100,000. Officers: President, G. E. McFarland; vice-president, W. J. Van Allen; secretary and treasurer, J. D. Mason; board of directors, C. F. Hall, W. J. Van Allen, G. E. McFarland, J. D. Mason and Charles Hutchinson.

JEFFERSON CITY, MO.—Kansas City, Ozarks & Southern Railway Company, of Ava. $300,000. To build and operate a standard gauge electric railway between Mansfield, Wright County, and Ava, Douglas County, a distance of fifteen miles. Incorporators: J. H. Murray, H. E. Bush, J. M. Adams, A. P. Miller and J. S. Clark, all of Ava.

TILLAMOOK, ORE.—Tillamook Public Service Company. $500,000. Incorporators: John K. Kollock, M. A. Zollinger and Frank E. Smith. To build electric railroads, telephone and telegraph systems, wharves and docks, flumes, boats, steamships, power and electric light plants, etc., and to carry on a public service system. Principal office and place of business, Bay City, Ore.

TELEPHONE AND TELEGRAPH.

JAMESTOWN, N. D.—The Mutual Electric Construction Company has completed a telephone line from this city to Spiritwood Lake and to Courtenay.

READING, PA.—The Pennsylvania Telephone Company has let a contract to R. J. Gordon, of Philadelphia, for underground work in various parts of the town.

LOUISVILLE, NEB.—Farmers west of Louisville have incorporated the Farmers' Co-operative Telephone Association, and will complete a telephone system as soon as possible.

CHICAGO, ILL.—The Chicago Telephone Company announces general reductions in rates around Chicago, in a few cases as high as fifty per cent, as a result of a change in the measurement to the block system, following the introduction of shorter toll lines.

POTTSVILLE, PA.—The American Union Telephone Company has secured possession of the telephone lines of the United Telephone and Telegraph Company. In connection with this deal the company also leased the lines of the Friedensburg, McKeansburg and Ringtown companies.

CHARLESTON, S. C.—The Bell Telephone Company has made a contract to establish a long-distance line connecting Manning with the main line at Pinewood. The line will be operated in connection with the Manning telephone exchange, but it will be strictly a toll line. The service is to be established in sixty days.

LACONIA, N. H.—At the annual meeting of the stockholders of the Citizen Telephone Company the report of the treasurer, S. B. Cole, showed the company as being in a most excellent financial condition with a large increase in subscribers. The officers elected were: President, Dr. A. W. Abbott; treasurer, S. B. Cole; clerk, E. H. Shannon; manager, William D. Johnson. Directors: Dr. A. W. Abbott, John H. Dow, H. Beckford, True E. Prescott, V. C. Haserick, John W. Ashman, of Laconia; C. H. Odell, Sanbornton, and Judge W. B. Fellows, of Tilton.

NASHVILLE, TENN.—A charter has been granted to the Citizens' Telephone Company, of McMinnville, Warren County, which proposes to construct a telephone line from that place to Nashville and various other places in Tennessee. The incorporators are: James Walling, Butler Smith, J. M. Lively, A. H. Faulkner and J. J. Morford. The company has an authorized capital stock of $5,000. It proposes to construct a telephone system and lines from McMinnville, in the county of Warren, to the following cities and towns: Tracy City, Beersheba, Spencer, Sparta, Smithville, Woodbury, Nashville and Manchester, such lines beginning at McMinnville as a common centre and radiating to the several cities and towns specified.

LEESBURG, VA.—At a meeting of the Leesburg Telephone Company Charles P. Janney was elected president; W. S. Jenkins, vice-president, and C. H. Shipman, secretary and treasurer. The officers were elected members of the board of directors, together with W. E. Garrett and M. E. Church. A charter has been applied for from the state corporation commission. The new company will be known as the Leesburg Telephone Company. Incorporated. The stock is nearly all taken by local men. Arrangements are being made to rebuild the old plant as soon as possible, installing a new up-to-date switchboard and central office equipment. All subscribers will be given local and long-distance connections, which will enable subscribers in the town of Leesburg to get direct connection with Washington and other outside points. M. E. Church will have charge of the rebuilding and installing of the new plant.

ELECTRICAL SECURITIES.

While there were several reactions in the stock market last week, prices, as a rule, closed higher, with more interest manifested than for some time. This increased speculation is thought to be due to the analysis that is being made of the future value of many of the stocks now held at rather low figures. There are many signs of betterment in trade conditions. Large orders for copper and for iron and steel, and the re-employment of large numbers of laborers indicate a revival in the metal industry. The American Railway Association reports a large decrease in the number of idle cars, and with the movement of the tonnage indicated by the expanding volume of orders for new material and the promise of bounteous crops bids fair to bring on a day of new profits for the railroad companies. It must be remembered, too, that there have been put into effect many radical savings in operating expenses. These retrenchments, in view of the great increase in business soon to become a fact, should mean largely increased dividends next year.

Dividends have been declared upon the following electrical securities: Guaranteed dividend of 2½ per cent on the stock of the Brooklyn City Railroad Company, payable July 15. Electric Company of America; regular semiannual dividend of 3½ per cent to stock of record July 10. New Hampshire Electric Railways; semiannual dividend of 1 per cent on the preferred stock, payable July 31. Havana Electric Railway Company; a dividend of $1.50 a share on preferred stock, payable August 15. Electric Bond and Share Company; regular quarterly dividend of 1¼ per cent on the preferred stock, payable August 1. American Light and Traction Company; quarterly dividend of 1¾ per cent on the common stock, placing the stock on a 7 per cent basis. The stock was placed on a 6 per cent basis one year ago, and two years ago the dividend was increased from 4 per cent to 5 per cent per annum. The regular quarterly dividend of 1½ per cent on the preferred stock has also been declared. Both dividends are payable August 1. New Orleans City Railway Company; dividend of 1 per cent on the common and the semiannual dividend of 2½ per cent on the preferred stock, payable July 10. East St. Louis & Suburban Company; regular quarterly dividend of 1¼ per cent on the preferred stock, payable August 1. United Traction Company; regular dividend of 2½ per cent on the preferred stock, payable July 20. Omaha Electric Light and Power Company; a semiannual dividend of $2.50 per share, payable August 1.

ELECTRICAL SECURITIES FOR THE WEEK ENDED JULY 11.

New York:	*Closing.*
Allis-Chalmers common	11¼
Allis-Chalmers preferred	34
Brooklyn Rapid Transit	48⅝
Consolidated Gas	126¾
General Electric	136¼
Interborough-Metropolitan common	11
Interborough-Metropolitan preferred	30⅛
Kings County Electric	112
Mackay Companies (Postal Telegraph and Cables) common	64⅛
Mackay Companies (Postal Telegraph and Cables) preferred	65¾
Manhattan Elevated	137
Metropolitan Street Railway	23
New York & New Jersey Telephone	105
Western Union	55⅛
Westinghouse Manufacturing Company	55¾

Boston:	*Closing.*
American Telephone and Telegraph	116
Edison Electric Illuminating	211½
Massachusetts Electric	46½
New England Telephone	112
Western Telephone and Telegraph preferred	65

Philadelphia:	*Closing.*
Electric Company of America	10¼
Electric Storage Battery common	30
Electric Storage Battery preferred	31½
Philadelphia Electric	9⅝
Philadelphia Rapid Transit	15⅛
United Gas Improvement	85½

So far more than one-third of the Electric Company of America stock to be transferred into American Gas and Electric Company bonds, under the proposition made by the Electric Company of America shareholders to the Gas & Electric Company, has been deposited.

Chicago:	*Closing.*
Chicago Telephone	139½
Commonwealth Edison	105
Metropolitan Elevated preferred	49¾
National Carbon common	69½
National Carbon preferred	111

The net gain by Chicago Telephone in the number of telephones installed last month was 3,322, as against 1,858 the previous month and 3,340 a year ago. Total gain this year, 16,632, as against 18,835 a year ago. Telephones in service, 219,396, as against 189,794 a year ago. Unfilled orders, 5,000.

PERSONAL MENTION.

MR. WILLIAM E. EVANS, who has been superintendent of the Butler (Mo.) city electric light plant for the past year, has resigned. He will go into the electrical supply business in Butler.

MR. C. L. REEDER, of Baltimore, Md., has been appointed engineer in charge of the work on the electric plant which will be built at Laurel, Md., in the next few months. Mr. Reeder's appointment has been confirmed by the council.

MR. J. D. WELSH, general superintendent of the Colorado & Southern Railway, has been made superintendent of the Denver & Interurban Railroad Company, an electric line, which has been taken over by the Colorado & Southern Railway.

MR. GEORGE A. McKINLOCK, president of the Central Electric Company of Chicago, with his son Alexander, has been catching bluefish off the shores of Long Island during the past week. They were guests on board Commodore W. L. Candee's yacht.

MR. C. S. HAMMATT, vice-president and organizer of the Florida Electric Company, of Jacksonville, Fla., has disposed of his stock in the company and resigned as vice-president to engage in the precious stone business as the Hammatt-Dickey Company, which is now being organized.

MR. CLARENCE J. McQUAIG, of McQuaig Brothers, Montreal, Canada, has been elected a member of the board of directors of the Tri-City Railway and Light Company, which controls all the street railway, gas and electric light business in the cities of Davenport, Iowa; Rock Island, Moline and East Moline, Ill.

MR. ADOLPH A. THOMAS has become associated as an assistant in the office of Brown & Williams, attorneys and counsellors, making a specialty of patent law. Mr. Thomas, after completing the course in chemical engineering at the Case School of Applied Science, graduated from the law school of Georgetown University. For four years he was an assistant examiner in the electrical division of the United States Patent Office.

MR. CHARLES S. DAVIS, of Somerville, Mass., has assumed charge of the Marlboro Electric Company, Marlboro, Mass., *vice* Eugene W. Godfrey, resigned. Mr. Davis is a graduate of Tufts College, and was also a student in electricity at the Massachusetts Institute of Technology. He was assistant electrician for the Boston & Maine Railroad, and consulting engineer for Concord, Mass., when it was putting in its electric lighting plant. He was the first manager of this plant, and for five years was master electrician in the construction and repair department of the Charleston Navy Yard.

MR. ALBERT J. MARSHALL has severed his connection with the engineering department of the Holophane Company, New York city, and has associated himself in the capacity of chief consulting and designing illuminating engineer with the Bureau of Illuminating Engineering, 437 Fifth avenue, New York city. He was associated with the engineering department of the Holophane Company for about three years, and during the last year of his connection with that company had charge of the engineering department. Previous to his work with the Holophane Company he was associated with the Baltimore branch of the Welsbach Company for a short time. Mr. Marshall has been a prominent figure in spreading the gospel of illuminating engineering in every part of the country. He completed a short time ago a series of illustrated lectures on the subjects of "The Fundamental Principles of Illuminating Engineering" and "The Proper Use of Artificial Light." This lecture trip covered a period of about nine months and a distance of approximately 26,000 miles. About fifty-five or sixty of these lectures were given in various parts of the United States. Mr. Marshall's work with the engineering department of the Holophane Company, the exceptional opportunity which he had to meet practical problems in all classes of service and all existing conditions throughout the country, and his natural adaptability for this work, have fitted him to take up his work as an independent engineer in the science and art of illuminating engineering. The Bureau of Illuminating Engineering has been in existence for about two years, and during that time has engineered the illumination of several notable buildings. On a number of occasions the bureau has been retained by the government for working out the illuminating problems in several of the federal buildings.

MR. ALBERT J. MARSHALL.

ELECTRIC LIGHTING.

ELDORADO SPRINGS, MO.—It is stated that the plant of the Eldorado Springs Electric Company, which was recently destroyed by fire, will be rebuilt if the owners can make satisfactory terms with the city. C. A. Ross, of Wilmette, Ill., is president of the company.

PALESTINE, TEX.—At the annual meeting of the Palestine Light, Heat and Power Company the following officers were elected: E. C. Beach, of Little Rock, president; Volney Foster, of Chicago, vice-president; A. T. Knies, general manager. The affairs of the company were shown to be in good condition.

APPLETON, WIS.—The plant of the Appleton Paper and Pulp Company will be operated only about three months longer. When the present supply of pulpwood is exhausted the plant will be closed down and the company will begin the erection of a new electric power-house, the power to be used for commercial purposes.

RAYMOND, WASH.—The South Bend-Raymond Electric Company has elected the following officers: J. L. Meyers, of South Bend, president; P. H. Ridgway, of Seattle, vice-president and manager; R. L. Fisher, of Seattle, secretary and treasurer. Directors: F. F. Fisher, P. H. Ridgway, Martin Welsh, Mr. Raymond, W. S. Cram, R. L. Fisher, superintendent.

NATCHEZ, MISS.—Pursuant to a decree of the chancery court of Adams County, O. Pollock, as trustee, has sold the local property of the Southern Light and Traction Company, consisting of the electric railway and electric light and gas plants, the purchaser being Lynn H. Dinkins, president of the company and president of the Interstate Trust and Banking Company, of New Orleans, who offered $5,000 above the liabilities of the company. The property is assessed at $125,000 on a fifty per cent valuation.

RED BLUFF, CAL.—The organization of another electric power company in Tehama County is likely to be consummated in the near future. Valuable water rights on Mill Creek are controlled by Gorham King, T. H. Ramsey, S. P. Stice, E. D. Gardner estate, Smith Crowder, W. A. Fish and W. F. Luning, and negotiations are now under way for their sale to a party of capitalists who expect to expend over a million dollars in the construction of a plant to generate many thousand horse-power of electric energy. The completion of the Northern Electric to Red Bluff and Redding will create a demand for a large amount of power.

BALTIMORE, MD.—At the annual meeting of the stockholders of the Mount Washington Electric Light and Power Company, held at the company's offices in Mount Washington, the following officials were elected: President and general manager, Thomas W. Offcutt; vice-president, Alten S. Miller; secretary and treasurer, Harry J. McIntyre. Directors: Thomas W. Offcutt, Alten S. Miller, S. Davies Warfield, Walter R. Townsend and Richard A. Bevan. The Mount Washington Company supplies electric current for public and private lighting in the villages of Arlington, West Arlington, Pikesville, Melvale, Mount Washington, Ruxton, Sherwood, Govanstown, Towson and Lutherville.

SALT LAKE CITY, UTAH—The Davis County Light and Power Company, with a capital of $50,000, in shares of the par value of $1 each, has filed articles of incorporation with the secretary of state. The officers are: J. D. Wood, president; J. H. Wilcox, vice-president; N. B. Stadley, manager; E. F. Richards, secretary-treasurer, and they with O. C. Dixon, constitute the directorate. The company takes over for $6,359 five miles of poles and wire in Farmington, three miles of the line outside of the city limits, a franchise from Davis County, a year lease of water power, a filing on water in Farmington Cañon and the good will of the present holders. Of the capital stock $43,641 is for the present left in the treasury.

INDUSTRIAL ITEMS.

THE CENTURY ELECTRIC COMPANY, St. Louis, Mo., in bulletin No. 10 describes and illustrates its single-phase motors. Copies of this bulletin will be furnished to those interested upon request.

THE AMERICAN CONDUIT COMPANY, Marquette Building, Chicago, Ill., manufacturer of bituminized fibre conduit for underground construction, is mailing a postal-card illustrating a line entrance insulator for bringing high-tension lines through the wall of the central station.

THE MANHATTAN ELECTRICAL SUPPLY COMPANY, 17 Park place, New York city, has ready for distribution its catalogue No. 24, entitled "Something Electrical for Everybody." This catalogue is supplemented by the confidential net price list, which is available to those interested in the distribution of electrical supplies.

THE CONDIT ELECTRICAL MANUFACTURING COMPANY, Boston, Mass., has moved to larger quarters at 76 and 78 Batterymarch street. The company owns its own building at this point, and is occupying five floors and a basement. There are complete facilities for large stockrooms and storerooms and for office departments.

THE RIDGWAY DYNAMO AND ENGINE COMPANY, Ridgway, Pa., announces that in order to take care of its southern territory it has concluded negotiations with the Machinery Sales Agency, at 1021 Prudential Building, Atlanta, Ga., to handle its complete line of side and centre-crank engines, as well as direct-current electrical machinery.

THE GENERAL COMPRESSED AIR AND VACUUM MACHINERY COMPANY, St. Louis, Mo., has prepared several very interesting booklets devoted to compressed-air and vacuum cleaning apparatus and tools. The compressed-air and vacuum system of dust removal is gaining great favor for factories, hotels, residences, central stations and car-cleaning departments. This apparatus is arranged to be driven by electric motors, engines or manually, according to the style of equipment desired. Full information and illustrated catalogues will be furnished upon request.

THE ARTHUR JONES COMPANY, Old Colony Building, Chicago, Ill., has issued a booklet giving special prices on motors and generators, new and second hand, for both alternating and direct current. These machines are of recent and modern design, built in modern shops to meet all conditions. Prices are figured very closely and on the basis of spot cash on delivery. The company has unexcelled facilities for executing orders, and will be pleased to give full information to those interested upon request. The list given in this book is very complete, and it should be in the hands of every one finding it necessary to make quick purchases of electrical apparatus of this character.

THE WESTERN ELECTRIC COMPANY, 463 West street, New York city, has issued a number of attractive booklets on intercommunicating telephone equipments. These equipments are manufactured both in key and jack types for residence, factory and office use. The booklets call attention to the time-saving features and convenience of the intercommunicating system, also to the elimination of telephone operating expenses and the availability of the system for use at all hours of the day and night, owing to a telephone operator not being required. Explicit instructions are given regarding the installation, wiring and operation of each of the different equipments listed.

THE STANDARD GAUGE MANUFACTURING COMPANY, Syracuse, N. Y., has ready for distribution bulletin No. 1, devoted to "Eclipse" oil filters. "Eclipse" continuous-oiling systems and exhaust heads. The filter department is an addition to its well-known line of standard indicating and recording gauges for all purposes. Besides the standard line of "Eclipse" oil filters, this bulletin illustrates special forms for particular conditions; also several arrangements of the component parts of the "Eclipse" oiling system, so that engineers will find the problem of the recovery and purification of lubricating oil worked out for plants of all sizes and types. Copies of this bulletin will be furnished to those interested upon request.

Record of Electrical Patents.

Week of July 7.

892,410. SWITCH MOUNTING. Arnold E. De France, Toledo, Ohio. The switch is mounted on a rectangular metal box.

892,411. INSULATED COUPLING FOR ELECTRIC CONDUCTORS. John J. Dossert, New York, N. Y., assignor to Dossert & Company. A two-part coupling joined by a third threaded member and enclosed in a two-part insulator.

892,419. SYSTEM OF ELECTRIC-MOTOR CONTROL. Fletcher D. Hallock, Wilkinsburg, Pa., assignor to Westinghouse Electric and Manufacturing Company. Locking means are provided, preventing the closing of the controller if any part of the starting resistance is short-circuited.

892,421. SYSTEM OF ELECTRIC-MOTOR CONTROL. Ford W. Harris, Wilkinsburg, Pa., assignor to Westinghouse Electric and Manufacturing Company. The starting circuit is automatically opened if the individual starting switches are closed out of the predetermined order.

892,429. SYSTEM OF ELECTRIC-MOTOR CONTROL. Henry D. James, Pittsburg, Pa., assignor to Westinghouse Electric and Manufacturing Company. Means are provided for delaying the closing of the individual starting switches.

892,445. ELECTRIC LIGHTING SYSTEM FOR AUTOMOBILES. Frank L. Parrill, Vincennes, Ind. The lighting dynamo is mounted on a rocking shaft allowing its driving wheel to be brought into contact with the main driving wheel.

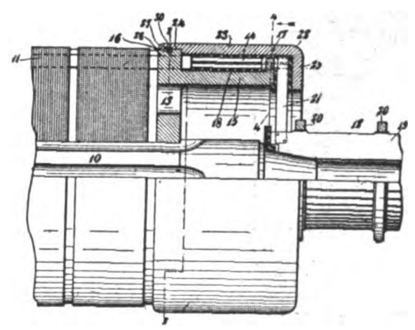
892,464. CONTROLLER. Emmett W. Stull, Norwood, Ohio, assignor to Allis-Chalmers Company. A magnetically operated switch is provided which opens the circuit when the controller reaches its first operative position as it is moved backward.

892,470. SYSTEM OF DISTRIBUTION. Hermon L. Van Valkenburg, Norwood, Ohio, assignor to Allis-Chalmers Company. A polyphase system utilizing a number of series transformers, enabling one instrument to be connected into any phase.

892,475. ARC-LAMP REGULATING MECHANISM. Ernest P. Warner and Carl Wiler, Chicago, Ill., assignors to Western Electric Company. A retarding device is attached to the feed clutch.

892,487. TURBO-GENERATOR CONSTRUCTION. Alfred H. Wouters, Norwood, Ohio, assignor to Allis-Chalmers Company. The commutator leads are carried on a ring and held by a second ring enclosing them.

892,500. BATTERY INDICATOR. Rufus N. Chamberlain, Depew, N. Y., assignor to Gould Storage Battery Company, New York, N. Y. A permanent magnet indicator.



892,487.—TURBO-GENERATOR CONSTRUCTION.

892,554. SHUNT. Frank W. Roller, Plainfield, N. J., assignor to Whitney Electrical Instrument Company. A convoluted conductor with its convolutions extending in planes at right angles to the terminals.

892,608. ELECTRIC BATTERY. William Morrison, Chicago, Ill., assignor to George Rumrill Coryell, Chicago, Ill. The negative element supports a deposit of bromin.

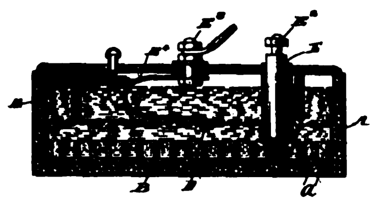
892,616. MEANS FOR CONTROLLING MACHINERY. Henry A. Peters and Charles W. Morgan, Paterson, N. J. The controllers are locked by an electrically actuated detent.

892,626. ELECTRICAL INSULATOR. Hugo F. Selinger, St. Louis, Mo., assignor to Wagner Electric Manufacturing Company, St. Louis, Mo. An insulator for transformer terminals or the like.

892,636. CONTROLLING APPARATUS FOR RAILWAY APPLIANCES. Hiram C. Williams, Utica, and Francis B. Harrington, Albany, N. Y., assignors to General Electric Company. A time-limiting circuit-closer actuated by the interlocking levers.

892,637. CONTROLLING MEANS FOR RAILWAY APPARATUS. Hiram C. Williams, Utica, and Francis B. Harrington, Albany, N. Y., assignors to General Electric Company. The magnet controlling the movement of the signaling lever is itself controlled by a switch requiring a predetermined interval for closing.

892,655. BATTERY-CHARGING APPARATUS. Frederick G. Duryee, Fort Wayne, Ind. A vibrating pole changer.



892,608.—Electric Battery.

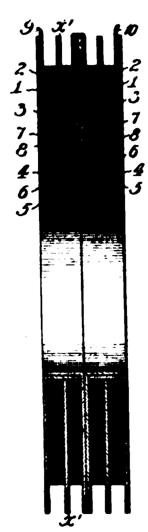
892,656. CONTROLLER FOR ALTERNATING-CURRENT MOTORS. George W. Euker, Boston, Mass., assignor to Diehl Manufacturing Company. A variable inductance is inserted in one of the leads.

892,670. ELECTRIC SNAP SWITCH. Walter S. Mayer, Philadelphia, Pa., assignor to the Machen & Mayer Electrical Manufacturing Company, Philadelphia, Pa. A pivotal snap switch.

892,677. SAFETY APPLIANCE FOR ELECTRIC RAILWAY TRAINS. Edwin T. Munger, Chicago, Ill. A device for rendering the motor controller inoperative whenever the brakes are out of order.

892,712. SAFETY APPLIANCE FOR ELECTRIC RAILWAY TRAINS. Adolph H. Daus, Chicago, Ill. Electromagnetic means placed on the car which prevent the operation of the controller except when shunted through a low-resistance path, which is maintained as long as the brakes are in operative condition.

892,713. SAFETY DEVICE FOR ELECTRIC TRAINS. Adolph H. Daus, Chicago, Ill. A device for rendering both controllers on an electric car inoperative when the brake system is out of order.



892,763.—Induction-Coil Unit.

892,734. SAFETY APPLIANCE FOR ELECTRIC RAILWAY TRAINS. Harley A. Johnson, La Grange, Ill. A magnetic device permitting car controllers to be used when the brakes are in operative condition.

892,749. ELECTRIC SIGN APPARATUS. Richard F. Le Brocq, Etna, N. J., assignor of one-half to Edwin J. Selley, New York, N. Y. A switching device for controlling a number of lamp circuits.

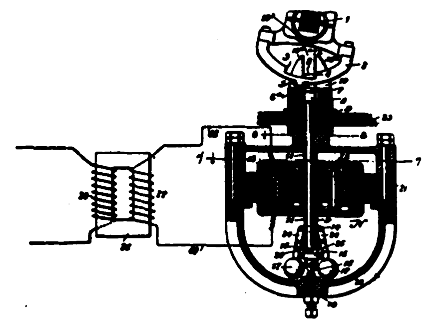
892,755. PLUG FOR ELECTRICAL CONNECTIONS. Walter S. Mayer, Philadelphia, Pa., assignor to the Machen & Mayer Electrical Manufacturing Company. A plug formed of nonconducting material with perforations for receiving the conductors.

892,763. INDUCTION-COIL UNIT. Carl A. Pfanstiehl, Highland Park, Ill. A coil section formed of a pair of outer spools, one of which fits over the other.

892,764. HIGH-FREQUENCY APPARATUS. Charles C. Ruprecht, Cleveland, Ohio, assignor to the Cleveland High Frequency Company, Cleveland, Ohio. The combination of a circuit, having in series therewith the primary coil of a transformer with a circuit including the secondary winding of the same transformer.

892,768. ELECTRIC ARC LAMP. Charles P. Steinmetz, Schenectady, N. Y., assignor to General Electric Company. A smoke flue is provided within the lamp.

892,770. APPARATUS FOR GOVERNING THE PASSAGE OF CARS OR VEHICLES ALONG A RAILWAY. John D. Taylor, Wilkinsburg, Pa., assignor to the Union Switch and Signal Company, Swissvale, Pa. The controller on the car is unlocked electromagnetically.

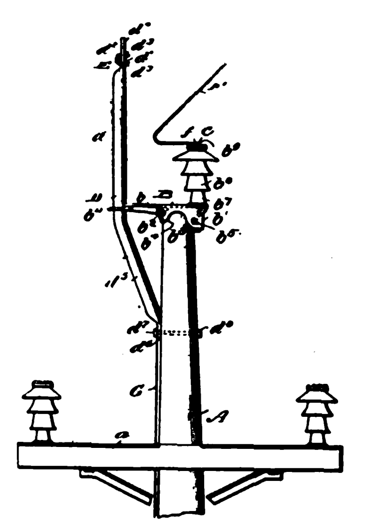


892,770.—Apparatus for Governing the Passage of Cars or Vehicles Along a Railway.

892,814. ELECTRIC INDICATING SYSTEM FOR RAILWAYS. Herbert G. Dorsey, Ithaca, N. Y. A pair of conductors is carried parallel to the track and each train is equipped with a generator, the voltage of which depends upon the speed of the train, the current from which actuates indicators on other trains.

892,822. POLE-TOP CAP. James W. Fraser, Charlotte, N. C. A cap for a transmission-line pole, which provides a support for an insulator pin.

892,841. SYSTEM OF CONTROL. Henry D. James, Pittsburg, Pa., assignor to Westinghouse Electric and Manufacturing Company. A plurality of electromagnetic switches is provided for cutting out steps in the starting resistance.



892,822.—Pole-Top Cap.

892,857. ELECTRICALLY OPERATED SIGNAL FOR RAILWAY CROSSINGS. George W. Lancaster, Richmond, Va., assignor to Lancaster Automatic Railway Crossing Company, Inc., Richmond, Va. Certain of the signals at a railway grade crossing are released by the approach of a train, the others remaining locked.

892,868. CLUTCH. Thomas G. Morse, Erie, Pa., assignor to Morse Iron Works, Erie, Pa. The clutch is applied by two electromagnets.

892,872. ELECTRIC SWITCH. Hervey H. McIntire, South Bend, Ind. A switch the contacts of which are movable longitudinally.

THE OSCILLOGRAPH IN THE SHOP.

The oscillograph is certainly one of the prettiest of research instruments devised by physical science in recent years. Thanks to the ingenuity of Duddell and others we have here an instrument capable of following rapidly changing physical effects; and by the means of auxiliary devices we may either make permanent records of transient phenomena or actually watch these changes as they take place. Until the development of the oscillograph the student of electrical science was considerably handicapped, as all his instruments gave merely averaged values, and when these are used for measuring rapidly changing quantities, such as exist in a circuit through which an alternating current is flowing, the values thus found seem to indicate a departure from the laws known to apply to circuits in which the current is steady. For these reasons it has become more or less customary to study the flow of alternating currents from the mathematical rather than the physical standpoint; the fact that Ohm's law is always the fundamental law of electric flow, no matter what the type of current, is often overlooked.

When attempts are made to study the character of change going on in the alternating-current circuit, before the oscillograph was available, tedious step-by-step methods were necessary, and these were applied at times under a disadvantage, since the points of the curves thus obtained were not instantaneous values, but averages of many such values. But the oscillograph enables us to trace not only the true instantaneous changes, but also to record, when desired, the average series of changes which are going on. The instrument thus became one of considerable scientific importance, and we must credit it with many valuable researches. Nevertheless, it is usually looked upon as a purely scientific instrument, whose place is in the laboratory, not in the shop. For this reason, a short paper contributed to the July issue of the *Electric Journal* by H. H. Gallehar is interesting, as he takes the stand that a suitably designed and equipped oscillograph is an essential piece of apparatus for every testing floor. Such an instrument is not difficult to use and may be easily set up and is not easily influenced by external forces. When such a device is available many troublesome questions which arise during the testing of any electrical device may at once be answered. It will not only show the true character of the current and electromotive-force waves, but it will also show the true difference in phase between them. It gives the testing-floor staff the ability to watch the effects of any changes in conditions upon the apparatus being tested and to determine when the desired conditions for testing have been obtained. It thus forms a valuable addition to the usual equipment of the testing floor.

It is always interesting to notice the adoption of what is considered a purely scientific instrument to the utilitarian purpose of the testing floor, but it is even more interesting to notice how scientific the methods of the testing floor have become. Indeed, so far as the study of electrical apparatus is concerned, it would be pretty difficult to draw a line separating the so-called practical from the really scientific work.

A NOTEWORTHY HYDROELECTRIC SYSTEM.

One of the interesting and instructing papers presented at the recent meeting of the American Institute of Electrical Engineers at Atlantic City was that by Mr. J. W. Fraser which describes some of the important phases of the hydroelectric developments in North and South Carolina.

On the Pacific Coast and in other sections of the Far West fuel is expensive, and cheap power, or rather cheaper power than can be produced in a steam-driven station, is the desired end and the engineers of the transmission systems which have been built up out there have had this end constantly in view. To supply this demand for power it has been found profitable to transmit it electrically over distances far greater than those covered by transmission systems elsewhere in the world. On the other hand, at Niagara Falls and one or two other places a different condition exists. Here the reason for development was not the high cost of fuel but the opportunity offered by the enormous power represented by the falls and the possibility of producing mechanical power in large quantities at a less cost than could be done by the use of comparatively inexpensive fuel. There was, at the time the work was undertaken, no immediate market for this power; the nearest large market was Buffalo and it was anticipated that the output of the power plants at the falls, after it had been decided to develop them electrically, would be transmitted and sold at distant points. The outcome, however, was somewhat different, for while a good deal of energy was disposed of in Buffalo and other nearby towns, a greater part of it was sold to new industries established at the falls to take advantage of the low rates made them.

In the Carolinas, however, a condition different from either of the above faced those who undertook to develop the water powers of these states. Here there is a large market for power, not concentrated in one point, but scattered over a not very large territory. There are many cotton mills thickly dotted throughout the central part of the two Carolinas which offer the main outlet for the sale of energy. At these mills power was already supplied by steam-driven plants of fairly good efficiency and reliability. Fuel is not particularly costly, and as many of the plants are comparatively new they were not handicapped with old and inefficient machinery. The electrical system must, therefore, compete with good steam-power plants and it must not only be able to sell energy to the mills at a less cost, all things considered, than the mills can make it for themselves, but it must insure as great reliability as a simple steam engine belted to a series of line shafts.

For these reasons reliability became the controlling factor in design, since no mill could afford to depend upon unreliable power, however low the price; yet it was necessary to secure this reliability without an excessive cost of construction. To this end the engineers of the Southern Power Company, whose system is the one described by Mr. Fraser, studied carefully the insulation problem and adopted a factor of safety higher than that usually deemed satisfactory. The apparatus was selected with special reference to reliability and the protective system was thoroughly planned. On one of the more recent lines the factor of safety has been again raised, but this is with the expectation of doubling the transmission voltage on this line some time later. The practical reasons which lead to the selection of 44,000 volts for the present system of transmission lines and for the adoption of the frequency of sixty cycles are given in Mr. Fraser's paper, which is published elsewhere in this issue. Had the present company initiated the work the selection might have been different; but it had to consider one hydroelectric station already existing and the many motors which were in operation in certain of the mills.

There is another interesting phase of the power development of the Southern Power Company's system which was brought out in a few remarks made by Mr. Lee in discussing Mr. Fraser's paper. As on most of the southern rivers the problem of handling floods is serious and the variation in the flow of the rivers is great, the main power station is primarily planned for only the minimum flow. The question then rises if it will be profitable to install more apparatus in the power station and a reserve steam plant which will run during, say, two months of the year. This is one of the points discussed by Mr. Fraser and his conclusions are interesting; but Mr. Lee brought out another phase of the question which we do not remember to have heard discussed before. It will be remembered that a large number of these southern mills have adopted the electric drive because of the increased and improved output of the mills thereby secured, and although a power company might not be able to offer them terms sufficiently low to induce them to abandon their own power station, it might sell them energy at very low rates for about six months of the year and let them run their own power plants during the months when the water is low. To make such an arrangement profitable would require a much larger hydroelectric development than the usual considerations would warrant, but the plan may lead to a solution of the secondary power development entirely different from that arrived at by Mr. Fraser.

To indicate the importance of this southern power system, it may be said that it owns eleven power sites aggregating 150,000 horse-power, and as Mr. Fraser's paper deals mainly with the transmission-line problems some may be interested in learning in more detail the character of the hydroelectric stations which the Southern Power Company is installing. An excellent description of these was given by Mr. Fraser in the ELECTRICAL REVIEW, September 8, 1906.

SLAVES OF THE CLOCK.

Until recently we have looked upon the clock as an interesting physical device adapted by man to divide the day and night into convenient arbitrary periods; but it seems that in London, at least, the clock has risen from this menial position to one more dignified and important. Over there, it appears, the clock regulates man's actions, rather than man the clock's. It fixes the time for his getting up and going to bed; when the office is to be opened and when closed and the time of day when he shall rest his weary body. His brain, we surmise, needs no rest, either because it is never greatly exercised, or else, perhaps, because it has been worn beyond repair. At least, these are the impressions given one when reading the discussions of the proposed plan to shift the working period of the day an hour ahead during the summer and back again to its normal position during the winter, merely by moving the hands of the clock. As a simple suggestion and with the idea of saving a part of the expense of lighting streets and homes by inducing men to start their work earlier in the day, stopping, of course, just that much sooner in the evening, the idea might call forth a few interesting psychological remarks, but when a bill is introduced into Parliament for carrying out this plan, one begins to wonder by what mental process the originator of this plan and those who favor it arrived at the conclusion that the mere shifting of the hands of a clock at the dead of night will bring about a complete rearrangement of the working hours in the British Isles.

The measure is known as the "Daylight Saving Bill," a name which fits it about as well as it itself will fit in with human habits. Those in favor of the scheme seem to be under the impression that since the banks and telegraph offices of London do not open until the summer sun has been trying to shine through the London fog for five or six hours, no one else goes to work any sooner than that, and because custom has fixed the hour for opening certain offices at nine or ten o'clock, or even later, as the case may be, the only way they see of changing this custom is to change the clock. It seems to be a childish way to bring about a reform. Every one is to start to work during the summer an hour earlier than he is accustomed to, but his clock is to show the same old time; therefore, he will not be able to resent the change. But why, if the plan should work successfully during the summer months and show an unquestioned saving of daylight—why should the country return to the old plan during the winter, as it is not apparent that either method would be more economical of light than the other during the short winter day in England?

These questions, however interesting, are psychological rather than electrical and hence we should perhaps be more concerned about the effect the proposed plan would have upon the electric light companies of the British Isles; should not any such attempt to curtail their sales of energy be resented? Yet we have not been so careful in our use of light heretofore, and too frequently we are satisfied if we pay the lighting bills, caring little how the light itself is used. Hence this sudden conversion and a consequent effort to abandon old and wicked ways should be received with caution. Yet we doubt very much, even supposing every one minded the clock, if there would be such a great saving of artificial light as is promised. Would not those who now enjoy the night as a time for pleasure rejoice so much the more at having an hour more for enjoyment that they would unwittingly draw out the time to an hour and a half, or maybe two, with considerable benefit to the lighting companies and with perhaps some detriment to their own welfare? With the latter consideration we have no concern, and since it does not seem likely the lighting companies will suffer seriously from the plan, we are not much alarmed at the prospect presented. We therefore await the issue of this campaign without undue anxiety, leaving it to the Englishman to fight the matter out with his clock, for as Humpty Dumpty said, "The question is, Who is to be master?"

REFUSE DESTRUCTORS AND POWER PLANTS.

During the presidential address of Mr. Herbert Talbot before the Incorporated Municipal Electrical Association of Great Britain at the meeting held in June, the speaker referred briefly to the performance of the refuse destructor plant at Nottingham, England, and from the experience gained there drew an interesting conclusion. The conclusion is about as follows: Town refuse is a more expensive fuel than coal under the conditions existing at Nottingham; hence, it would be cheaper for the electrical system not to utilize the steam produced in this destructor and to produce all of its steam in its boiler plant. To do so would not involve any increase in the staff of the station and indeed would rather improve, as a whole, the operation of this plant, since the load-factor of its boilers is lowered by the operation of the destructor plant. Taking a broader view, however, it is admitted that burning is the best method of disposing of city refuse, and the heat thus produced might as well be utilized. It is then merely a question whether the destructor plant is to be operated for destroying purposes alone and the cost of so doing frankly paid, or whether it is to be operated in connection with the electrical supply system and the latter is to be saddled with the cost of destroying the refuse. The latter arrangement probably results in a small saving to the town, but it rather complicates the work of the electrical department.

THE MANUFACTURER AND THE ENGINEER—AND ENGINEERING.

A somewhat unusual communication on the subject "Should Manufacturers Cease Doing Free Engineering" appears in this issue. For its originality, if for no other reason, it is entitled to consideration. The suggestion therein embodied is certainly radical and, whatever the merits of the case presented, it could only be introduced by a series of transition stages. It would be difficult to conceive of a sudden reversal of the custom which has heretofore obtained, even though the resulting benefits should be all that our correspondent would expect. The subject is important and timely. No doubt there will be forthcoming expressions of opinion from the various sources interested.

Should Manufacturers Cease Doing Free Engineering?

To the Editor of the Electrical Review:

The series of communications on the subject "Is the Consulting Engineer Necessary?" which have appeared in recent numbers of the London *Electrician* and your own British namesake, the *Electrical Review,* and the editorial comments thereon, have probably come before you and your readers.

The consideration of these writings has induced an idea which I herewith lay before you in the hope that it will either be approved and confirmed and lead eventually to a change in the present order of things, or its fallacy pointed out.

My suggestion is, that no manufacturer should bid on apparatus except under specifications from the prospective purchaser or his engineer, and that the manufacturing companies cease making plans and specifications. This suggestion is made in the interests of both the manufacturer and the consulting engineer, but the benefits would accrue principally to the manufacturer. The reasons which appear to make this course advisable are:

(1) The manufacturers would eliminate the cost of an enormous amount of futile engineering, done for people who have not the means to carry out their schemes nor the power to interest capital in them.

(2) The sales departments would have their work, records and expenses greatly reduced because of the elimination of projects which can never be brought to fruition.

(3) Manufacturers of high-grade apparatus would have a better opportunity of getting business on a basis of merit and worth.

(4) Business would be done between the manufacturer and an engineer, and therefore more understandingly, and on a better basis and at a lower cost.

(5) The practice of having one manufacturer prepare plans and specifications at his own expense, to be hawked about to other manufacturers, would be done away with.

(6) Where a prospective buyer applies to several manufacturers for plans and specifications it means that an equal number of specifications—no two of which coincide—are made for a single installation. This obvious and expensive waste of work would be avoided.

The manufacturers could confine their attention to turning out apparatus at the lowest cost consistent with the production of high-grade machinery, reducing their general and sales expenses, because in nearly every instance requests for quotations would come from responsible parties who would be actual purchasers, for no penniless promoter would retain a consulting engineer.

The adoption of this proposed system would require either an agreement among all the manufacturing companies or the independent action of the head of some company who is sufficiently big, broad, strong and wise to take this action, knowing that by his reduction in cost and the friendly attitude of the engineering profession toward any policy which would thus advance its interests, his company would possess no small advantage and would reap the reward of sanity and good judgment.

Engineer.

New York, July 11, 1908.

FINANCIAL REPORTS OF ELECTRICAL COMPANIES.

KANSAS CITY HOME AND LONG DISTANCE TELEPHONE COMPANIES.

The report of the Kansas City Home and Long Distance Telephone Companies for the year ended March 31, 1908, shows gross earnings of $955,212, an increase of $162,338; net earnings of $462,901, an increase of $85,738, and surplus after charges of $258,917, an increase of $68,033.

The Toledo Home Telephone Company, of Toledo, Ohio, reports gross earnings for the year ended December 31, 1907, of $354,618, an increase of $39,330, and surplus after charges of $129,091, an increase of $15,033.

The Kinloch Long Distance Telephone Company, of Missouri, shows gross earnings for the year ended December 31, 1907, of $1,139,151, an increase of $148,911, and surplus after charges of $282,425, an increase of $89,858.

LAKE SHORE ELECTRIC COMPANY.

The Lake Shore Electric Company reports gross earnings for May of $69,538, a decrease of $4,344; net earnings of $29,498, a decrease of $1,421, and surplus of $3,686, a decrease of $3,919. For five months the gross earnings were $307,439, a decrease of $10,521, and net $118,251, a decrease of $4,941. After allowing for interest charges there was a deficit of $10,174, an increase of $15,227.

CHICAGO RAILWAYS COMPANY.

Since the beginning of the present fiscal year, on February 1, the Chicago Railways Company has shown increases in both gross and net earnings. The April, March and February reports, which complete the first quarter of the fiscal year, are given in detail as follows:

Earnings.	April, 1908.	March, 1908.	February, 1908.
Passenger	$847,220	$840,743	$742,826
Sales of power	1,440	1,552	......
Other income	16,775	15,437	16,116
Gross	$865,435	$857,732	$758,942
Expenses:			
Maintenance of structure	$54,262	$47,262	$30,087
Maintenance of equipment	80,688	69,943	61,245
Operating cars and power plants	356,190	371,276	364,525
General	113,585	99,595	88,362
Real estate income	5,000	3,624	4,008
Taxes	16,608	16,609	16,609
Totals	$626,333	$608,309	$564,836
Balance (actual)	239,102	249,423	194,105
Balance, 30 per cent of gross	259,630	257,320	227,683
Interest, 5 per cent on value of property	136,492	136,065	135,788
Net income	$123,138	$121,255	$91,895
Division:			
City's 55 per cent	$67,726	$66,690	$50,542
Chicago Railway's 45 per cent	55,412	54,565	41,352

As shown by the above figures, the actual operating expenses in April were seventy-two per cent of gross, in March the percentage was seventy-two, and in February they were seventy per cent. This is due to the work of rehabilitation, but after the first part of the work is completed the ratio should decrease rather than increase.

The terms of the ordinance provide that seventy per cent shall be charged to income account for operation. At the end of the year any excess of that figure will be paid into the earnings account out of the capital account, unless the cost of operating should fall below that figure during succeeding months of the year.

The Chicago Railways Company's balance sheet, as of April 30, 1908, compares with that of March 31, 1908, as follows:

ASSETS.	April 30.	March 31.
Road and equipment	$33,030,238	$32,758,146
Cash	323,866	1,357,241
Total	$33,354,104	$34,115,387
LIABILITIES.		
Capital	$32,589,047	$32,589,047
Reserve for damages	580,098	545,758
Due city of Chicago	184,959	980,582
Total	$33,354,104	$34,115,387

The total passengers carried by the Chicago Railways Company lines, cash fare, free and on transfer, increased 1,603,376 in April and 1,092,794 in March. The earnings per car-mile and per passenger are also given in detail for the two months named.

Passengers carried:

	April, 1908.	March, 1908.
Revenue passengers	17,132,869	16,935,066
Free passengers	215,777	184,724
Transfer passengers	11,667,959	11,866,843
Total	29,016,959	28,486,633

NATIONAL ELECTRICAL CONTRACTORS' ASSOCIATION.

EIGHTH ANNUAL MEETING, HELD IN CHICAGO, ILL., JULY 15, 16 AND 17.

The eighth annual meeting of the National Electrical Contractors' Association was held at the Auditorium Hotel, Chicago, Ill., July 15, 16 and 17. The convention was opened with a session of members and guests on Wednesday morning, July 15. A number of contractors from several states were in attendance and there was present also a large representation of manufacturers.

The address of welcome was made by Henry Newgard, president of the Illinois Electrical Contractors' Association. The first paper, entitled "The Electrical Contractor's Opportunities in the Illuminating Field," was read by the author, George Loring. An abstract of this paper is presented elsewhere in this issue.

A paper entitled "The Relations Between the Underwriter and the Contractor" was read by W. H. Merrill, Jr., manager of the Underwriters' Laboratories, Chicago, Ill.

These papers were discussed briefly, both Mr. Loring and Mr. Merrill replying to numerous questions. Mr. Merrill invited those attending the convention to visit the laboratories, which are conducted under the direction of the National Board of Fire Underwriters.

The contractors were the guests of the Chicago Electric Club at luncheon, and in the afternoon a business session was held at two o'clock.

On Wednesday evening banquets for both the ladies and gentlemen were held in the Auditorium Annex, the banquet rooms being thrown together after the repast and a fine vaudeville programme thoroughly enjoyed.

On Thursday morning there was an open session for members and guests. J. R. Cravath presented a very interesting discourse on "Illuminating Engineering." In the course of his remarks Mr. Cravath said: "The contractor who has a sufficient knowledge of illuminating engineering so that he can go to the dissatisfied user of an unsatisfactory lighting installation and guarantee him more results for the money he is expending for light can create business and get work which otherwise would not be available." He called attention to some of the first principles of interior illumination and indicated the proper method of attacking such problems of artificial illumination as would ordinarily come within the province of the electrical contractor.

Alex Dow addressed the session on the topic, "The Relations Between the Lighting Company and the Contractor," followed by Seth B. Wetherbee, on the topic, "The National Electrical Contractors' Association."

On Thursday afternoon a brief business session was held, and the members were later taken in tally-hoes to the National League Park, where an exciting baseball game between the New York and Chicago teams was witnessed. The party returned to the Auditorium in tally-hoes. During the afternoon the ladies enjoyed an automobile trip through the south parks and boulevards.

At 7.30 o'clock Thursday evening the members met in business session, the ladies attending the performance of "The Top o' the World" at the Studebaker Theatre. At nine o'clock a Rejuvenation of the Sons of Jove was held at which fifty new members were initiated into the mysteries of the order.

On Friday all the members and guests enjoyed an all-day outing to Michigan City, going by way of the steamship Theodore Roosevelt. A repast was served on both trips and while at Michigan City there were races for the ladies, a fat men's race, potato race, swimming race and a baseball game between the eastern and western contingents, the former winning by a score of ten to seven.

The following officers were elected for the ensuing year:

President, G. M. Sanborn, Indianapolis, Ind.

First vice-president, M. L. Barnes, Troy, N. Y.

Second vice-president, Charles R. Krieder, Chicago, Ill.

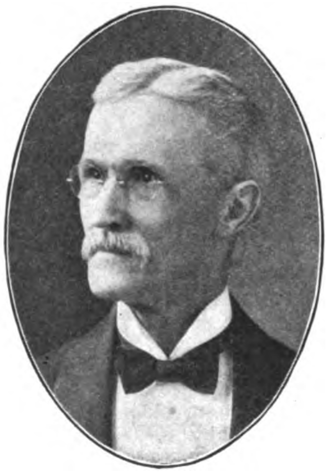
Third vice-president, H. S. Potter, Boston, Mass.

Treasurer, John R. Galloway, Washington, D. C.

Secretary, W. H. Morton, Utica, N. Y.

Sergeant-at-arms, J. C. Sterns, Buffalo, N. Y.

G. M. SANBORN,
President National Electrical Contractors' Association.



JOHN R. GALLOWAY,
Treasurer National Electrical Contractors' Association.

W. H. MORTON,
Secretary National Electrical Contractors' Association.

There was very little display of electrical apparatus by the manufacturers, but there was a fine attendance of representatives, among whom the following were present:

George S. Searing, Chicago sales manager, Hart & Hegeman, Hartford, Ct.

W. W. Cheney, Jr., president; Julian S. Jackson, sales manager; A. Benson, secretary, International Electrical Meter Company, Chicago.

G. W. Cooper, district sales agent; Frank E. Johnson, district sales agent, the Ohio Brass Company, Mansfield, Ohio.

John Brooks, sales manager; G. V. W. Ingham, Chicago sales manager, Pass & Seymour, Solvay, N. Y.

I. A. Bennett, W. J. McKenna, I. A. Bennett Company, Chicago.

Sherman M. McFedries, secretary and treasurer; W. R. Harvey, J. L. Schureman Company, Chicago.

J. G. Pomeroy, western sales manager, Adams-Bagnall Electric Company, Cleveland, Ohio.

G. A. Furbeck, Furbeck & Hurt, St. Joseph, Mo.

Arthur O. Einstein, sales manager, Crescent Company, Chicago.

James G. Gilchrist, general manager;

H. W. Markham, sales manager; H. F. Frosch, Federal Electric Company, Chicago.

Frederick L. Merrill, Chicago manager Triumph Electric Company, Cincinnati, Ohio.

George Loring, Shelby Electric Company, Shelby, Ohio.

W. J. Guntz, G. R. Clover, Nernst Lamp Company, Pittsburg.

M. B. Austin, president; W. A. Brown, treasurer; R. J. Thorne, Michigan representative; Arnold H. Friend, M. B. Austin Company, Chicago.

Edwin R. Rockwell, secretary Guarantee Electric Company, Chicago.

C. E. Corrigan, vice-president and general manager; Milton Mill, southwestern sales agent, National Metal Molding Company, Pittsburg, Pa.

Victor L. Crawford, W. N. Matthews & Brother, St. Louis, Mo.

George C. Knott, H. E. Watson, Benjamin Electric Manufacturing Company, Chicago.

H. B. Crouse, president; F. F. Sheel, western manager, Crouse-Hines Company, Syracuse, N. Y.

Homer E. Niesz, manager Electrical Trades Exposition Company, Chicago.

M. F. King, George C. Richards, P. J. Cratty, Richard Wildauer, Thomas Grier, American Circular Loom Company, Chelsea, Mass.

Henry Newgard, president Henry Newgard & Company, Chicago.

J. R. Wiley, J. E. O'Neill, R. S. Hopkins, E. J. Pietzcker, Standard Underground Cable Company, Pittsburg, Pa.

H. D. Haring, O. O. Tucker, M. R. Lash, F. H. Van Gorder, H. W. Dye, H. F. Boardman, J. H. Dutton, G. H. Lounsbery, George H. Porter, H. M. Kennedy, F. A. Henderson, L. J. Baldwin, H. M. Post, E. S. Kiefer, E. H. Peterson, Western Electric Company, Chicago.

E. J. Johnson, Consumer's Rubber Company, Bristol, R. I.

William Low, president; E. R. Field, H. R. Remington, Perry R. Boole, C. A. McCarthy, H. E. Sanderson, A. J. Seltzer, Robert Mitter, Electrical Appliance Company, Chicago.

A. S. De Veau, T. C. Walsh, De Veau Telephone Manufacturing Company, Brooklyn, N. Y.

F. F. Corby, C. W. Larsen, D. L. Markle, Mark Manufacturing Company, Chicago.

U. S. Armstrong, American Conduit Manufacturing Company, Pittsburg, Pa.

E. P. Bartlett, H. G. Wilson, John A. Roebling's Sons Company, Trenton, N. J.

W. Ennis, manager Pittsburg office, Buckeye Electric Company, Cleveland, Ohio.

Oscar Carman, General Electric Company, Schenectady, N. Y.

W. Johnson, Clark H. Methot, Manhattan Electric Supply Company, Chicago.

C. M. McDonald, Allis-Chalmers Company, Chicago.

P. F. Lyons, National India Rubber Company, Bristol, R. I.

E. B. Kittle, manager Chicago office; Alfred E. Braddell, Harry H. Hornsby, Sprague Electric Company, New York, N. Y.

F. B. Badt, P. A. Westbury, F. B. Badt & Company, Chicago.

Robert Garland, H. D. Hodskinson, H. O. Waterman, Safety Armorite Conduit Company, Pittsburg.

Skyles R. Fralick, Blake Signal and Manufacturing Company, Boston, Mass.

H. M. Frantz, H. W. Johns-Manville Company, New York, N. Y.

E. R. Blyler, Crescent Insulated Wire and Cable Company, Trenton, N. J.

E. W. Kearns, Monarch Electric and Wire Company, Chicago.

W. P. Crockett, Bossert Electric Construction Company, Utica, N. Y.

Maurice Lewison, Detroit Insulated Wire Company, Detroit, Mich.

B. J. Moorenhaupt, Dale Company, New York, N. Y.

American Telephone and Telegraph Company.

Hayden, Stone & Company have prepared a circular giving an exhaustive analysis of the American Telephone and Telegraph Company. The circular says that the company is fully financed for all present requirements, having paid off on July 1, $10,000,000 of American Bell Telephone four per cent bonds maturing on that date, and is now free of any floating indebtedness, and has an excess of $10,000,000 cash on hand. The capitalization, including bonds and notes amounting to $330,484,855, as well as the capital obligations of the subsidiary companies, is represented by property, the replacement value of which, without considering any value in rights of way or franchise or patents, is estimated at $10,000,000 in excess of the entire capital of every kind. The franchises and rights of way are in the greater part permanent, and could not be secured at the present time at any cost within limits. Never since its incorporation in the present form, in 1900, has the company failed to earn its entire fixed charges more than three times over. The circular says:

"No company could possibly attain the tremendous scope of the American Telephone and Telegraph Company, and remain local in any particular. As the American company has become national in the operation of its business, so it must surely become national in the method of its financing and in the demand for its securities. The evident and increasing attraction of its securities will draw capital from all parts of the country, and the shares of the company, already held by 25,000 investors, will become still more widely owned. The inevitable result will be the development of a large and active market for both the bonds and stock of the American company in the financial centre of the country, New York."

The New York, New Haven & Hartford Railroad to Build New Lines.

The New York, New Haven & Hartford Railroad Company has announced that it would expend $1,000,000 on the construction of three new trolley lines. The contracts are to be let at once, and work will be begun on all three lines this fall. One of these lines is to be run from Hartford to Middletown, another from Hartford to Boonfield and the third from Willimantic to South Coventry.

The expenditure on these roads will be the first that the New York, New Haven & Hartford road has made since the financial flurry of last fall, when the company began a policy of retrenchment.

Samuel Higgins, general manager of the New Haven, in discussing the electric system of the road, has expressed his own satisfaction with it and added that the company was well pleased with it. The system was constructed by the Westinghouse Electric and Manufacturing Company, and has a high-potential alternating-current with an overhead trolley.

Mr. Higgins said that the electrification of the New Haven had been so satisfactory in every respect that there had been no thought on the part of the company to substitute another system for the one now in use.

The last payment for the installation, said the general manager, had been made to the Westinghouse company about four months ago, which was further proof of the satisfaction of the railroad company.

SOME ENGINEERING FEATURES OF THE SOUTHERN POWER COMPANY'S SYSTEM.[1]

BY J. W. FRASER.

It has been aptly stated that in order to build a hydroelectric power system there are three fundamental requirements:

1. A sufficient source of power.
2. A market for the sale of power within economical transmitting distance.
3. The necessary capital.

It is not the intention of the writer to discuss these three fundamentals in a general way, but to take a concrete example and show how the conditions governing the sale of power must affect the design of the system as exemplified in that with which he is connected; to describe in a general manner this system and proposed ultimate extension of the same.

We will assume for the purpose of this paper a sufficient source of power, as any discussion of the hydraulic conditions would lengthen this paper undesirably. In passing, attention will be called only to the location of the various sites shown on the map, Fig. 2. These aggregate not less than 150,000 horse-power. One only, the Catawba plant of 10,000 horse-power capacity, was partially developed. The nine others are scattered along the Catawba River for a distance of 120 miles, with one on the Broad River about thirty miles west of Catawba station.

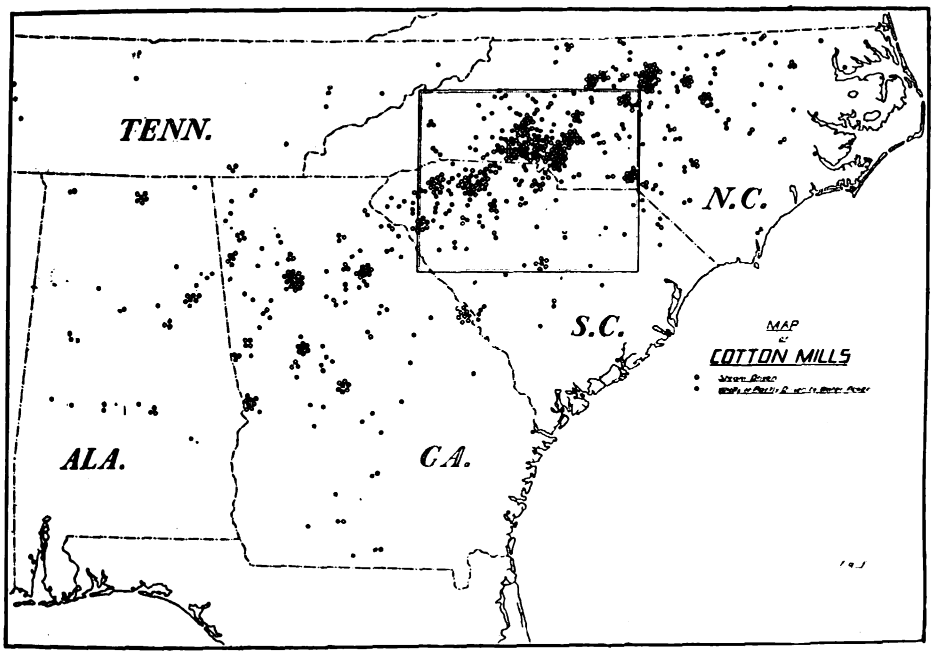

Fig. 1.—Map Showing Location of Cotton Mills.

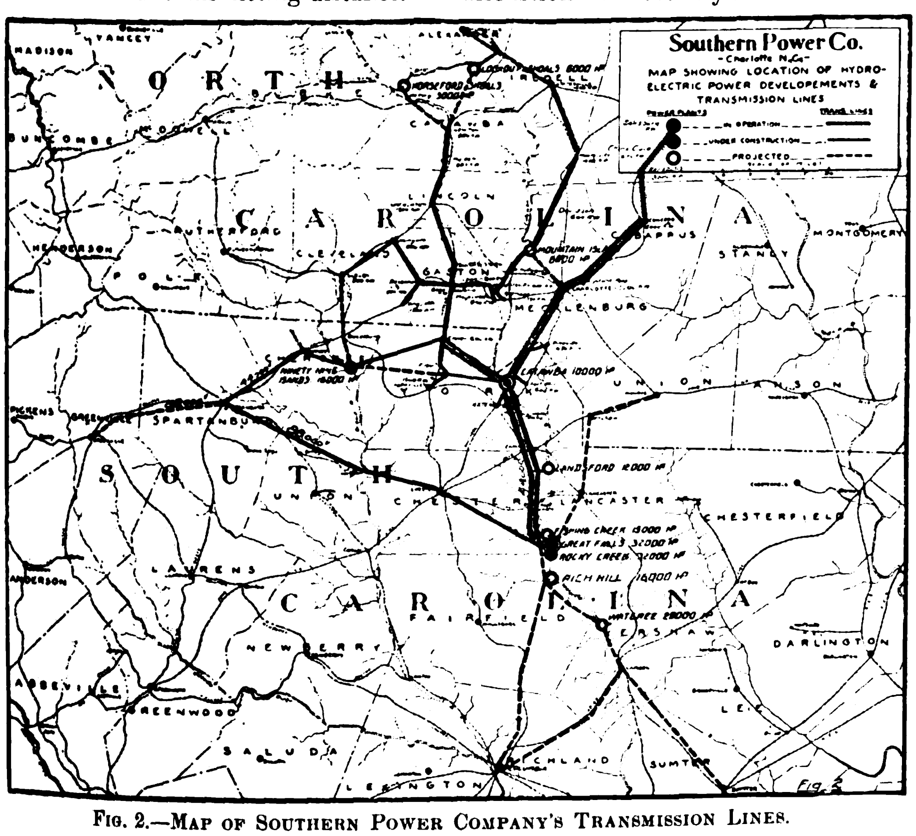

Fig. 2.—Map of Southern Power Company's Transmission Lines.

In discussing the market at the time when the Southern Power Company was organized (1905), attention is first called to the map, Fig. 1, showing the location of cotton mills in the South, on which is shown a rectangle covering an area of 140 miles north and south by 180 miles east and west, about equally distributed in North and South Carolina. This area is enlarged on the map, Fig. 2. It will be noted that it contains the largest number of mills that can be taken in by any such area in the South. It represents a power consumption of approximately 200,000 horse-power, one-fourth of which is water power. It is all within easy transmitting distance from the various power sites referred to in the above paragraph.

Before investing in these sites a careful investigation showed the average cost of power to be in the neighborhood of $34 per brake-horse-power-year of 3,366 hours; that, although a few of the larger mills had got this cost down to $30, the majority of the smaller mills could not produce power for much less than $40. With coal at $3.50, power could not be distributed for less than $28, even from large central steam stations. Experience acquired from the Catawba station and some smaller stations, to the records of which access was had, showed a fair margin of safety after transmission and other losses were taken into account.

True it is that in recommending investment in these sites it had to be considered that although the electric drive had demonstrated in some instances its reliability, convenience and economy, yet the unsatisfactory history in other instances, the general impression that power was produced for much less than it actually cost, and the fact that mill owners were averse to further investment, would make the sale of power a difficult matter. Still the main question which interested the investor was the cost of steam power, for prejudice could be overcome and the real cost of power could be demonstrated. In a further discussion of the market it is found convenient to treat of it under separate heads embodying the various engineering features.

Frequency—In determining what frequency would best suit the market condi-

[1] A paper presented at the annual convention of the American Institute of Electrical Engineers, Atlantic City, N. J., June 30. For a description of the different power sites owned by the Southern Power Company see Electrical Review, September 8, 1906, p 367.

tions the following had to be taken into consideration:

a. That the sixty-cycle generators at Catawba station and some 8,000 to 10,000 horse-power in induction motors receiving power from that station would have to be rewound or exchanged, if other than sixty-cycle were used, on account of the fact that separate lines would be too expensive and would complicate matters. Motor generators would make the cost prohibitive, because of the large number of distributing points.

b. That sixty-cycle motors to a total of approximately 8,000 horse-power were driving mills in the vicinity of proposed lines, which load might be obtained, provided the frequency was the same.

c. That there were also quite a few small city plants operating at sixty cycles. At present this might not amount to much, but the growth of these cities had to be considered, particularly in reference to arc lighting. In three years 2,500 arc lights have been put in service and if motor-generators had had to be installed the cost to small mill towns would have been excessive.

d. That a high frequency would give a better power-factor, due to the leading charging current.

e. That twenty-five-cycle generators, transformers and motors would cost at least ten per cent, twenty-five per cent and ten per cent, respectively, more than sixty-cycle generators, transformers and motors.

f. That there was very little prospect in the near future of a rotary converter or railway load, and there were plenty of cotton mills in the district covered to use all the power which could be generated from the rivers.

Against the above is the extra line drop, but when all the developments are completed very little power will be transmitted more than forty miles except over trunk lines where the drop may be taken care of by raising the generator electromotive force. For instance, the voltage at Catawba and at Spartanburg, two centres of distribution, can always be maintained at 44,000 volts.

These considerations seemed to favor sixty cycles, but as exact figures were necessary in this case the following rough calculation was made: The saving in cost of generators and transformers amounted to $75,000, and if the saving in copper due to increased power-factor is added the total will be in the neighborhood of $100,000.

There is an additional loss of about ten per cent of the loss which there would have been at twenty-five cycles and the integrated loss over the present lines when fully loaded will be in the neighborhood of twenty-seven per cent. In power

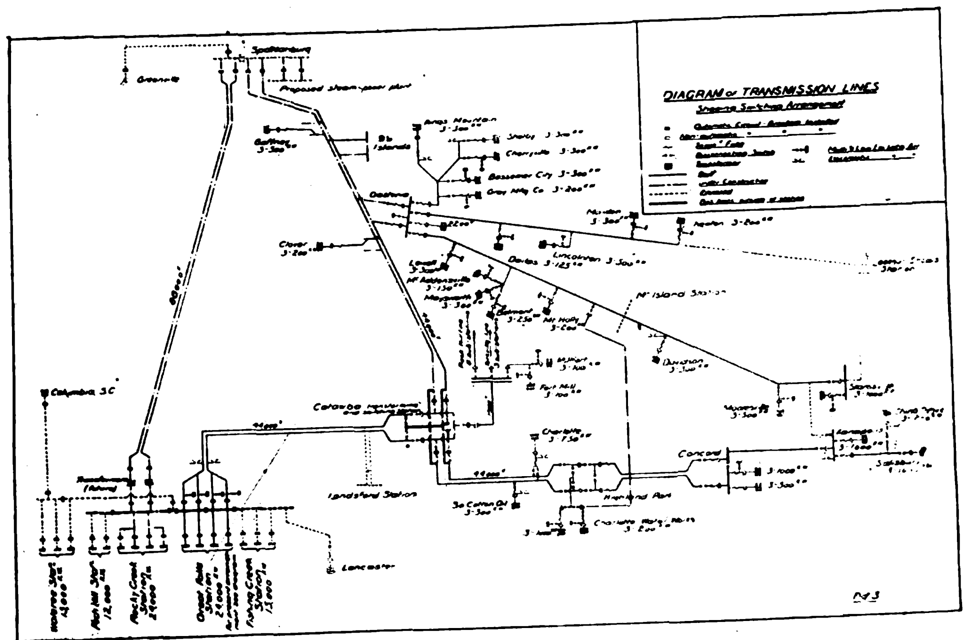

Fig. 3.—Transmission Lines and Switching Arrangements.

this amounts to ten per cent of twenty-seven per cent of 26,000 kilowatts = 700 kilowatts, which at $5 per kilowatt is $3,500. Capitalized at six per cent this amounts to $60,000—a balance of $40,000 in favor of sixty cycles. It is possible that a very careful analysis might show this loss to be a little greater but the error

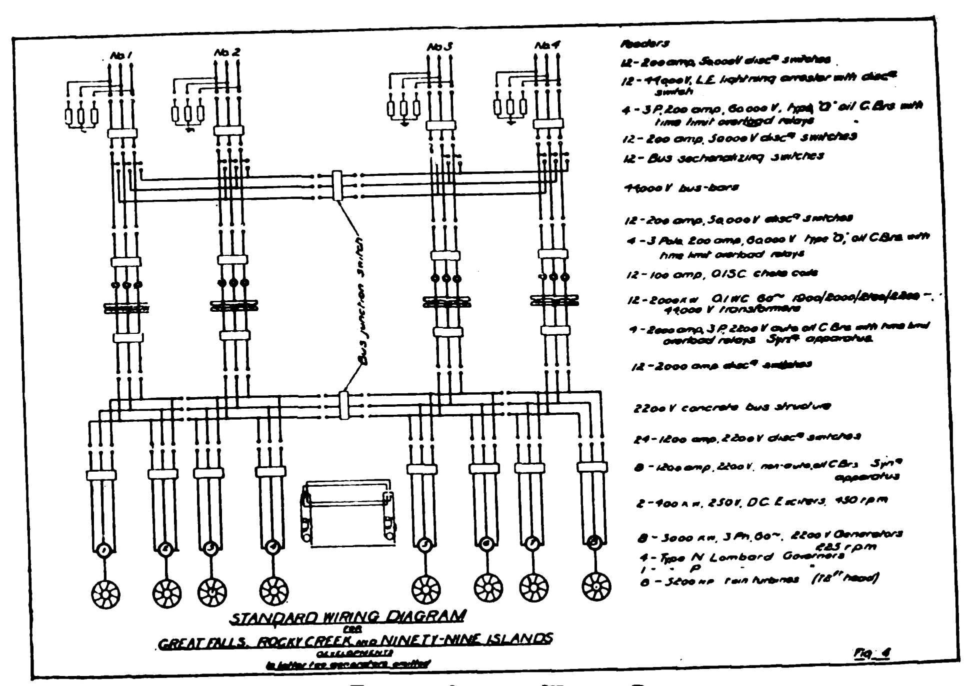

Fig. 4.—Type of Station Wiring Diagram.

can not be over twenty-five per cent, as the integrated loss referred to has been taken over a period of six months and covers losses from generators to meters on load. The only other error which could be made would be in estimating the line drop when the present lines were fully loaded, but as the drop on the present load has been measured the error could not be very large.

Considerations (*a*), (*b*) and (*c*) have been left out of the above numerical calculation but might easily amount to several times the figure mentioned.

Voltage—Some of the reasons for keeping the electromotive force as low as 44,000 volts were:

a. That 44,000-volt transformers would cost from eighteen per cent to thirty-three per cent, depending on the size, less than for 66,000-volt transformers.

b. That transformers and switches were more reliable at 44,000 volts.

c. That insulators would cost about eighty cents less each.

d. That line operation would be more successful.

e. That smaller transformer stations could be built.

It was estimated that the extra copper to give the same drop over the entire system at 44,000 volts as compared with 66,000 volts would not exceed the extra cost of transformers, insulators, substations, switches and other apparatus. The estimate proved correct. With the present 30,000-horse-power load there are on the system 72,000 kilowatts in step-up and step-down transformers and the additional cost if 66,000-volt transformers had been used would have been $64,000; additional cost of 30,000 insulators at eighty cents, $24,000; additional cost of thirty 66,000-volt substations, *i. e.*, twenty per cent on $125,000, $25,000; additional cost of step-up transformer stations, *i. e.*, ten per cent on $200,000, $20,000; a total of $133,000. Against this is the saving in copper in the transmission line had the higher electromotive force been used, roughly, fifty per cent, $130,000.

This shows a saving of only $3,000, but the present lines will carry a great deal more power than they are now carrying, which will increase this amount materially.

One line only of those proposed stands out as an exception, the trunk line running from Great Falls to Spartanburg and thence to Greenville, about 100 miles in length. This line now under construction will be so built that when overloaded at 44,000 volts delivered electromotive force it can be changed to 88,000 volts (*i. e.*, 100,000 volts at generating station). This will be accomplished at a very small additional expense by mounting pins and insulators similar to those now used on our wood-pole lines on the towers as shown in diagram, Fig. 5, for after conversion to a higher electromotive force these pins and insulators can be used on 44,000-volt lines, or this line may be permanently used for local distribution. The intention is that this 88,000-volt trunk-line will not be tapped at any point except Spartanburg. This could be done more easily by using 100,000-volt suspension-type insulators but it is felt that by the time it is necessary to change to the higher electromotive force there may be enough improvement made in these insulators to warrant the extra expense which would be incurred.

Transmission Lines—Further examination of the transmission-line map will show that two-thirds of the obtainable power is in the neighborhood of the Great Falls development, which position was selected as a main switching station, the idea being to mass the output of Great Falls, Fishing Creek, Rocky Creek and Rich Hill at this point on outdoor bus-bars and control the line switches from the operating room in this station.

The generators and transformers were designed to operate continuously at eighty-five per cent power-factor to take care of an induction-motor load, and at 115 per cent normal electromotive force to take care of line drop as the load increased. The main trunk line, from Great Falls to Catawba station, will take care of 20,000 kilowatts at eighty-five per cent power-factor, with a line drop of 13.5 per

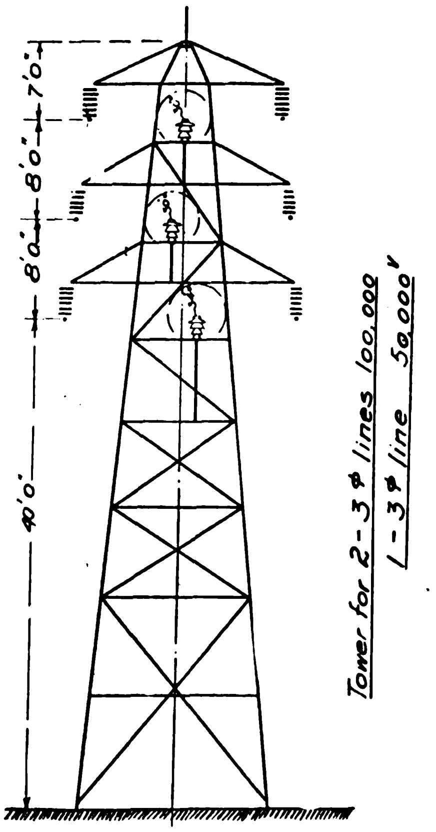

Fig. 5.—88,000-Volt Tower.

cent and a loss of 7.25 per cent. This represents the economical section of copper at twenty cents per pound with power costing $5 per kilowatt-year.

It should be pointed out before leaving the subject of transmission lines, that the impossibility of making contracts with mill owners on account of their skepticism with regard to the electric drive, before the greater part of the present lines was actually built, made the estimates on the amount of power to be sold in any one territory so difficult that the location and size of transmission lines could not be determined even approximately. In other words, where and in what amounts power was to be sold was a very uncertain matter.

This brought up the question of wood-pole lines *versus* steel towers. A little consideration showed that if the cost of towers per additional foot in height erected were $7 and copper were at twenty cents per pound, a No. 0 Brown & Sharpe gauge would be the smallest wire which could be strung economically on account of the increased sag in wires below this size for 500-foot spans; that a single-circuit tower line would cost approximately twice as much as a pole line and would last probably twice as long; that a double-circuit tower line would cost very little more than a double-pole line; and that it would be more economical for cotton mills to shut down for a small percentage of time than to pay the additional price for power which would be necessary to cover the extra expenditure for steel-tower lines. It therefore seemed good practice to build main trunk-lines of steel towers and all single lines below No. 0 gauge of wood poles.

Still another factor increased this difficulty. One large development under construction and several others recently financed by competing companies tended to make mill owners hold off for better prices. I refer to this merely to show how such a matter may affect the design. Considerable discussion resulted as to whether Great Falls and Rocky Creek should not be made into one development by means of a canal and pipe-lines. This would take at least as long again as to develop one source and would cost the same as separate developments.

(To be concluded.)

Extensive Trolley-Terminal Plans.

Plans were made known on July 16 for a new trolley terminal in Jersey City, which, it is said, would be one of the largest in the world. The terminal will be operated in connection with the tunnel system to Manhattan, and work on the improvement will be started in a few weeks.

It is planned to draw many of the New Jersey trolley lines to a point in Exchange Place, Jersey City. An underground passageway will run from the tunnel station to Exchange Place. A half dozen loops will be laid for the cars and sheds will be built. Trolleys from almost every district in Hudson County will be brought to the terminal.

Another transfer point in Jersey City may be at Henderson street and Newark avenue. It is proposed to divert several main lines to the point, thus enabling passengers to gain time in reaching the McAdoo tunnel.

Annual Convention of the American Institute of Electrical Engineers—III.

Report of Concluding Sessions, Thursday, July 2.

THURSDAY MORNING SESSION.

THE seventh session of the meeting of the American Institute of Electrical Engineers, which was held at Atlantic City, N. J., June 28 to July 2, inclusive, was opened on Thursday morning, July 2, at 9.30 o'clock, with President Stott in the chair.

The reports of the preceding sessions were given in the issues of the ELECTRICAL REVIEW for July 4, 11 and 18.

Dr. C. P. Steinmetz read a paper entitled "The General Equations of the Electric Circuit." Due to our incomplete knowledge of the phenomena resulting from the stored energy of the electric field, we are greatly hindered in a practically unlimited extension of high-potential transmission and distribution. The study of these phenomena represents the most important problem of electrical engineering. Dr. Steinmetz has been investigating the general equations of the electric circuit and here presents his first results. The work is still incomplete and in some instances may require modification. The paper represents an attempt to investigate mathematically the phenomena which may occur in the most general case of an electric circuit.

Dr. Steinmetz said that the investigation was incomplete, but brought out some important facts. One is that the general equation of a circuit shows that it may be considered as having two electric waves moving in opposite directions, each of which gives rise to a reflected wave. Another point is that when a transition takes place from one part of the circuit to another having different characteristics, there is both a voltage and a current transformation, and since both at the point of transition must be identical, there must be a sudden change in phase. In concluding, Dr. Steinmetz said that from what has already been done, he thought it safe to predict that in a few years we shall be able to treat the transient phenomena of electric circuits with as great accuracy as we can now deal with simple alternating currents. When we are able to do this we will be in a far better position to handle those disturbing effects on transmission systems which he calls lightning, and these will probably lose their terrors.

Dr. F. Bedell said that one great value of Dr. Steinmetz's classic paper was his interpretations of his own results. This is often neglected in such analytical studies. He pointed out that in the general case the current may not be the same in all points of the circuit, and said the hydraulic analogy might be applied to the general case by substituting an elastic tube for the rigid pipe. He pointed out that different components travel at different rates along the line, and this is the reason distortion takes place in telephone circuits.

D. C. Jackson said that in looking over Dr. Steinmetz's paper many old friends reappear, but there are also new equations which go much further than the old ones. He thought the best analogy for the general case was a vibrating string having different characteristics at different parts, these corresponding to different values of inductance and capacity.

Dr. Charles P. Steinmetz presented a paper entitled "Primary Standard of Light." In this it is pointed out that since light is a physiological effect, and not a physical quantity, it can not be measured in absolute physical units, but must be measured by comparison with an arbitrarily chosen standard of physiological effect. As a result of this, even the difficulties of reproduction and of maintaining its constancy are such as to involve errors very far beyond those considered permissible in physical measurements. A radical increase in the accuracy of reproduction and maintenance of a primary standard of light appears possible only by relating the standard of light in such manner to physical quantities that it can be determined by energy measurements. This led to the recommendation of defining the primary standard of light by the energy of radiation; but this requires a definition of the quality of radiation, since the physiological effect of radiation has no direct relation to the energy of radiation. Moreover, the physiological effect is not merely a function of the quality or color of the light, as lights of the same intensity and color—that is to say, physiologically identical—may be entirely different physically and represent different amounts of power. The power of the visible radiation is, therefore, not a measure of light. For this reason the definition of the absolute unit of light as the effect of one watt of power of visible radiation requires an arbitrary definition of the distribution of power throughout the visible range. Such a standard of light might be that given by black-body radiation at a different temperature and included between certain wave-lengths of the spectrum, but Dr. Steinmetz does not think that such a standard would be satisfactory, because the intensity of the red end of the spectrum is too high, the physiological effect too small, the absorption constant of glasses is different for different wave-lengths, any deviation of the radiator from black-body radiation offsets the result, and the color of the light would be yellow and not white. He thinks a more satisfactory primary standard of light, based on measurement of radiation power, can be produced by selecting three primary colors of the visible spectrum. Let these colors be of definite wave-length, about equally distant from each other, and of such character that they can be absolutely reproduced at high intensity; such, for example, as the spectrum lines of a luminous gas. Then define the unit of light as that given by one watt of power radiated at these three wave-lengths in different proportions, chosen so as to give white or yellow-white light. The primary unit of light may be taken as the physiological effect produced in this way. Such a standard requires three sources of monochromatic radiation which can be maintained constant with any desired exactness. The mercury-vapor lamp constitutes such a source. By properly adjusting the current density in the mercury-vapor lamp, three bands may be picked out: one in the violet, one in the green and one in the red, which are about equally distant. These are the lines having respectively the wave-lengths 43.55, 54.6 and 69.1 microns. To obtain them two low-temperature mercury lamps will be required for the blue and green and one high-temperature quartz lamp for the red. These could be maintained at constant radiation by maintaining the currents constant and also the condition of ventilation and surrounding temperature. By properly selecting the proportions of these colors, a white or, better, a yellowish-white light could be fixed upon as a standard. Such a selection of colors would give an exact numerical expression of the physiological color of any light by defining the ratio of three intensities of the primary elements.

A communication from Dr. W. S. Franklin was read, which said that the plan proposed by Dr. Steinmetz was novel and important, and he suggested that the Bureau of Standards, at Washington, take up the proposed standard and see whether it could be employed with any success. He did not expect complete success, as the inherent errors in any photometric measurements are too large.

Carl Hering said he was pleased to see the scientific standard of light proposed based upon the unit of power. He pointed out several advantages of the standard, one being that it did not require the determination of a new mechanical equivalent.

Dr. C. H. Sharp thought that the proposed standard gave promise of offering a general solution of the problem of devising a standard of light. He referred briefly to some of the other attempts, particularly that proposed by Violle, which depends upon the light emitting from a given area of molten platinum at the moment of solidification. He questioned whether such a mixture of monochromatic light as proposed would give the same color as a corresponding mixture of polychromatic light.

J. B. Taylor asked why Dr. Steinmetz had used the wave-length of the light waves for the scale of abscissas. The wave-length depends upon the medium, while the frequency is absolute and should therefore be employed. He asked also why Dr. Steinmetz had used the musical analogy in arranging his scale of colors. Pitches are recognized in sound, but not in color.

Dr. E. B. Rosa thought it would be a good plan to make a trial of Dr. Steinmetz's proposed standard, for even if the attempt to secure a satisfactory standard was unsuccessful, the investigation would be worth while for its own sake. He said the work was clearly one suitable for the Bureau of Standards.

Dr. H. S. Carhart pointed out that the proposed plan made use of three different wave-lengths, giving rise to three distinct sensations. He called attention to the fact that this method of mixing colors was entirely different from that of mixing colored pigments.

Mr. Hering then moved that the convention recommend to the board of directors the presentation of this proposed standard of light to the Bureau of Standards for investigation. The motion was carried.

Dr. Steinmetz, in closing the discussion, said that he had selected red and blue lights which were equidistant from the green, as this seemed to be the logical method of procedure. Regarding the criticism of his scale of abscissas, he had merely followed custom, as, of course, the proper factor to be considered was frequency and not wave-length. The mixture which he proposed would probably produce a yellowish light, and the proper proportion of colors to give a pure white light would probably be about fifty-five per cent of red, fifty-five per cent of green, and minus ten per cent of blue. Put in another way: The color of the mixture which he proposed as a standard would probably be identical with pure white light if ten per cent of blue be added. Referring to a statement which had been made that the value for the mechanical equivalent of light indicated that with an efficiency of 100 per cent we should get five and one-half candles per watt, Dr. Steinmetz said more recent researches had indicated that the true equivalent was probably 0.018, or something over fifty candles per watt for pure white light.

The paper by Carl Hering on "An Imperfection in the Usual Statement of the Fundamental Law of Electromagnetic Induction," which was read before the Philadelphia section of the Institute, on February 10 last, and which was discussed in the ELECTRICAL REVIEW for March 21, was brought up for discussion and a number of communications were read. The experiment consists in passing a loop formed of two springs attached to a galvanometer circuit over the pole of a horseshoe magnet and then drawing it off across the middle. The first movement gives a deflection; the second does not. Dr. C. P. Steinmetz considered the paper interesting since it called attention to a looseness in the form of expressing the law of electromagnetic induction which is frequently the cause of serious misunderstanding and the waste of much energy and time. This is illustrated in the many attempts to invent a coil-wound homopolar machine. The experiment described is not startling, as the reverse case—the continuous production of electromotive force without any change in the number of interleakages of the circuit with the magnetic flux—is illustrated in practically every unipolar machine. Maxwell's law is an integral expression derived from the general or differential law by integration over the whole circuit under the terminal or limit conditions of continuity of conductor and continuity of motion, and does not apply to Mr. Hering's experiment or to the general design of unipolar machines which do not fulfil the conditions of continuity of motion, but have parts of the conductor sliding over other parts. Faraday's expression is the general law, but in its application to unusual cases it must be kept in mind that the line of magnetic force is merely a pictorial representation of the magnetic field in space as characterized by two constants—intensity and direction. This pictorial representation, when carried so far as to apply to its physical existence, may lead to wrong conclusions; for instance, when discussing whether the lines of magnetic force of a revolving magnet move with the magnet or stand still. In such a field, if the intensity and direction do not change, the field is constant regardless of the motion of the magnet. Unfortunately, in teaching, instead of the general law of induction, there is frequently given to the student its specific application to the term of the closed continuous conductor as more convenient to illustrate and understand. While this is permissible in giving an elementary introduction for a complete understanding, it should be supplemented by an exact discussion of the general induction law; that is, the mathematical formulation of Faraday's pictorial representation.

Dr. A. E. Kennelly does not think that the experiment is in disagreement with either Faraday's or Maxwell's statement of the law. Maxwell's specifically rules out the case of multiple-connected regions, and when the law is stated it is inherently assumed that the circuit is not interrupted and re-established around a new boundary. In Mr. Hering's experiment this is practically what is done. The experiment shows, however, that the cutting of the flux is the primordial conception, and it is well to remember that this electromotive force occurs as much in insulators as in conductors, although it is only revealed in the latter case. In Mr. Hering's experiment the law is juggled by changing it from a simple connected to a multiple connected space, which is not permissible.

Dr. Elihu Thompson accepts the views expressed by Dr. Kennelly, holding that the slipping of the clips over the leg of the magnet virtually opens the circuit, inasmuch as an immovable section of the conductor is substituted in the gap where all the flux to be cut then exists. There seems to be one universal law which may be expressed as follows: "It is not possible, without chemical or thermoelectric action, to generate a continuous current in a closed circuit without sliding contacts"; or, to put it in another way, "A magnetic induction machine for direct currents must have a commutator or sliding contacts of some sort." Although apparently some such rectifying action might be secured by means of the change in resistance of selenium, due to its exposure to light or bismuth, due to its exposure to a magnetic field, such effects would be rather pulsating than rectifying.

Dr. W. S. Franklin, while agreeing in general with Mr. Hering, will not admit that Maxwell's statement of the law is not strictly correct. He does not think that those who accept Maxwell's generalization have forgotten the ideas of the actual cutting of lines of force, but it may be that they are likely to be led to forget this because of Maxwell's statement. Although we are obliged to think of one variable only changing at a time, we should never forget that all things may change together.

Percy H. Thomas said that the experiment is not conclusive, as the slipping of the springs over the magnet practically cuts off a portion of the circuit. The same view is held by G. T. Hanchett.

W. P. Graham believes it is open to question whether Maxwell's statement of the law is sufficiently precise, and he thinks that the cutting of the flux by the conductor is the point to be emphasized if Faraday's statement is to be preferred.

R. E. Hellmund, in a paper on "The Graphical Treatment of the Rotating Field," evolved diagrams by means of which nearly all the phenomena of the rotating field may be easily studied and the various factors necessary for the calculation of flux, exciting current, etc., are exactly determined. He develops diagrams for the fluxes in the individual teeth, for the space values of the total field, the potentials, time values of the total field, the equivalent sinusoidal field, showing the characteristics of the rotating field, the reactive effect of the secondary, and shows how the different coefficients may be deduced from these and the values thus found used in practical calculations.

C. A. Adams expressed his appreciation of Mr. Hellmund's paper, as the diagrams which the latter had developed show clearly the various relations existing in the motor. Such studies are good, not only for the student, but for the designer as well, because they give a visual picture of what is going on. In closing, Mr. Hellmund said that one of the difficult parts of the problem is the study of magnetic leakage and the determination of this factor.

Harold Pender presented a paper entitled "A Minimum-Work Method for the Solution of Alternating-Current Problems." The complex forms for impedance and admittance render the formulas for most alternating-current problems exceedingly complicated and numerical calculations become extremely tedious after the first and second operation. To avoid this a simpler method is desirable, and the one here described makes use of certain factors, namely, the ratio of the reactance to the resistance, which is called the reactance factor, and the ratio of the resistance to the impedance, called the power-factor. Introducing these factors into the expressions for the different quantities reduces them to simple forms and greatly lightens the labor of solving problems. The use of this method is illustrated by applying it to a number of alternating-current problems.

The discussion was opened by P. H. Thomas, who said that he did not think Mr. Pender's method and the use of the factors which he proposed would save much labor, but that his careful tabulation should be given the credit for lightening the work.

C. A. Adams said that he had used a similar method without, however, making use of the two factors proposed. He did not think that such short-cut methods were desirable for students' use, as the latter are then apt to lose sight of the true relations. They are, however, of value when there are a number of similar problems to be solved.

C. J. Fechheimer, in a paper entitled "The Relative Proportions of Copper and Iron in Alternators," discussed those features in the design of alternators which affect this ratio. The early generators were designed by rule-of-thumb methods, and the relative proportion of copper to iron was high. These machines had poor regulation and gave way to the so-called iron machines, in which the proportion of copper was less than that of the copper machines and the regulation was better, but the design more expensive and heavier. Hence it was endeavored to develop a cheaper design without sacrificing good regulation. This is the stage which has been reached to-day, and it demands an intimate knowledge of the results of previous work and careful balancing of the conflicting factors. The author derives equations for the weights of the principal parts of the alternator, the weight in each case being easily expressed as some factor which is easily determined, multiplied by some power of the flux per pole. The weight of these parts is then multiplied by the price per pound of material used and certain other factors introduced to allow for waste and for parts not included in the equation. The sum of these costs will give the cost of the material and the principal parts of the machine in terms of the flux, and it can then be determined what value of flux will give the minimum cost of the material. This being known, the rest of the design follows at once. The method is illustrated by the design of an 800-kilowatt alternator.

W. L. Waters, while expressing appreciation for such studies, said that machine design is an art rather than a science, and there is little real value in such academic studies. Past experience is the best guide in actual design.

C. A. Adams, while admitting that past experience must be depended upon to guide the designer, said that a general analysis of the different factors entering into the design is always of value and should help to reduce materially the amount of cutting and trying.

The session was then adjourned.

THURSDAY AFTERNOON SESSION.

The eighth and concluding session of the convention was called to order Thursday afternoon, July 2, at two-thirty o'clock, by President Stott, and three papers dealing with educational topics were presented in abstract.

M. W. Alexander presented a paper entitled "A New Method of Training Engineers." This calls attention to the desirability of giving the college student practical experience at the same time that he is following the theoretical studies. After some years' experience with the student course offered by the General Electric Company, at its Lynn works, Mr. Alexander has come to the conclusion that the best way of giving this practical training is to combine it with the theoretical work. The colleges should confine themselves strictly to teaching theory and underlying principles, and the student should alternate between the college and the shop. This should go on for four years and the entire senior year should be given up to theoretical work. This method is being tried at the University of Cincinnati, but Mr. Alexander thinks that the length of the period selected there—one week—is too short. The proper length can only be determined by experience.

D. B. Rushmore, in a paper entitled "The Relation of the Manufacturing Company to the Technical Graduate," discussed those qualities of the young engineer which render him most valuable to the manufacturing company. Naturally the man who has had a college training is more efficient than the one who has not, and the ranks of industrial concerns are now largely filled with college graduates. The importance of the technical organization is insisted upon, and it is thought that one of the most promising signs of the times is the close study and co-operation between manufacturers and colleges.

A suggestive paper, entitled "The Relation of the Manufacturing Company to the Technical Graduate," was read by B. A. Behrend, chief electrical engineer for the Allis-Chalmers Company. Mr. Behrend says that the qualities necessary for a man to rise to a high position in an engineering company are integrity, moral courage and intellect, and while there are many possessing any one of these qualities, there are few who possess all three. Yet it is such men that the manufacturing companies are looking for. He thinks that in supplying such men the colleges are doing remarkably well, but they are not always supported in the right direction by the manufacturing companies. The latter should not seek the man, but force the man to seek a position, thus not giving him an exaggerated opinion of his own importance. There is, unfortunately, among the colleges and graduates a most ominous disdain for painstaking accuracy and devotion to laborious detail which are so essential to all really great work in engineering. The wish to take up the work of some one else and make it a commercial success is easily explainable, but not so easily excused. This condition is really a menace to the stability and continued prosperity of manufacturing interests which must be remedied lest it produce a far-reaching result in discouraging graduates from the pursuit of new and important creative engineering work. Those who have been engaged in the building up of large manufacturing organizations have been impressed with the fact that the absence of moral qualities frequently mars a successful career, as frequently, perhaps, as the absence of purely intellectual qualities.

Before the discussion was taken up, the usual resolutions of thanks to the convention committee for the excellent arrangements it had made for the visiting members; to the Philadelphia section for its assistance in making the convention a success, and to Mr. Gummey, the proprietor of the Casino, who had allowed the Institute to make use of it for the reception Monday night, were adopted.

President Stott announced that, according to custom, Percy H. Thomas, the chairman of the papers committee, had tendered his resignation, and that A. H. Armstrong has been appointed chairman of the new committee. President Stott then thanked the various committees for their excellent work during the year.

The discussion on the three papers which had been read was opened by Professor J. P. Jackson, who said that if the results obtained by the training given in technical colleges are not satisfactory, the manufacturing companies have themselves to blame. They should get in close touch with the engineering departments of these colleges, find out what they are doing, and if they do not approve of the work as conducted, they should not hesitate to criticize. The manufacturers, however, should take care that they do not crowd out the so-called culture courses entirely in the technical work. Professor Jackson said that part of the blame for the present conditions must be laid on our general educational system. The study of history deals mainly with political movements and wars; it neglects scientific progress and the engineering work of the countries with which it deals. He suggested a number of subjects which might be profitably included in the engineering courses, such as railroad economics, labor problems, economic geography, etc. One method of improving the engineering courses, which is now to be tried, consists in appointing a number of consulting professors—men who are not engaged in teaching—whose duty it will be to advise with the department regarding the work to be taken up and the method of presenting it.

Mr. Behrend said that the co-operative courses recommended by Mr. Alexander and Mr. Rushmore could be adopted at but few colleges. Moreover, there are comparatively few manufacturing establishments at which the student really learns a great deal. He is more apt to be put to some manual work, such as drilling holes in name-plates, and kept at that for months without any opportunity to increase his knowledge of the process of manufacturing. One serious objection to such courses would be the prevention of concentration. No important problem can be solved in a week, or even a month, and to oscillate the students between the college and the shop would simply fritter away their time without giving them any thorough training. His criticisms were not directed toward the trade schools, which are necessary, but he thinks the co-operative courses would be a mistake for the college of high standing. He said frankly that the suggested plan would be one of the most vicious and dangerous innovations that could be made at a university.

P. H. Thomas believes that more commercial work is necessary to give the student true appreciation of the value of costs. The best way to secure this would be to overlap the last end of theoretical study with the first part of practical work. There is, however, a chance of overdoing this. It would not be safe to cut out shop work from the technical school, because it is there that the student learns the reason for the best methods. To send the students into the shop would distract their attention from theory and concentrate it on the commercial side. This would be dangerous.

Professor Morgan Brooks said he looked at the subject from the side of the technical school. The object of the school is to train men in character, and it would be difficult to do this if the student were oscillated from college to shop and back. For example, all colleges encourage athletics, but no student taking such co-operative courses as had been proposed could take any part in athletics at the college. There would also be much difficulty in administration with such co-operative work, particularly when special courses are offered. He thought it was a good plan for the students to enter some shop during the summer and possibly to take one year off and devote it to practical work, but these periods should not be less than one-half of the college year. He thought that a man who has done good practical work would have done still better work if he had had a college training.

Secretary R. W. Pope said he thought the Institute might profitably devote some of its energies to the training of parents. Few parents to-day seem to know what to do with their sons, and try to throw the responsibility for selecting their profession on the Institute or elsewhere. Moreover, the greater number of the members of the Institute could improve their own work by giving more attention to minor details. There is hardly an associate who applies for transfer to full membership in the Institute who seems capable of filling out properly the application blank.

Professor H. H. Norris said that the college work must necessarily be arranged for the average student, but unfortunately the average student prefers to work with his hand rather than his head. The favorite position in laboratory work is holding speed. A co-operative plan such as proposed would cause a severe loss of time when changing from one occupation to another. There is generally about a week lost after every term in college work, and to overcome this it had been suggested by the faculty of Sibley College, Cornell University, to break up the year into two long terms without any vacations at all, long vacations being allowed between the terms. Professor Norris thinks that the students are apt to lose interest in the theoretical work if their attention is directed greatly toward practical problems. They should be given just enough practice to enable them to think. The shop work must be kept at the college, as that is really the preparatory laboratory of the manufacturer.

Dr. Steinmetz said that from the college professor's standpoint, instruction in practice is desirable, but there is not time enough for it. The question, therefore, is not to teach what is desirable, but to teach what the student can not learn elsewhere. Hence the main effort should be to ground him thoroughly in science and give him a broad general culture. It is no criticism of the college to say that it does not turn out men fitted to drop into commercial positions. Indeed, he would suspect the training given at a college which claimed to do this, as it could only be done by omitting essentials. What the college should do is to make the students understand that upon graduation they have really only begun their work. The technical colleges are not the only educational institutions at which practical work may be taught, as there are trade schools which devote their entire time to training in the various trades. Then come the correspondence schools, which do work of a little higher class, and do it well. Next come the technical schools, which should carry the training of the men still further. There is one serious defect in the schools offering higher education: this is the inefficiency of the system, as the effort is made to work up the entire mass of material into engineers, although but few of them are really capable of developing into good engineers. In this way time and effort are wasted and the good men are neglected. Dr. Steinmetz spoke of the foreign colleges, particularly the German schools, where instruction is offered in every possible subject, but the responsibility for learning it is thrown upon the students. In this country, on the other hand, the college assumes a good part of this responsibility. The result of this is that American colleges produce few leading engineers. Far better results would be accomplished if the men were sorted out more stringently.

Professor D. C. Jackson said that the question is physiological and psychological. There is as good material to-day for producing such men as Watt and Newcomen as there was in the early days of the steam engine. He thinks that there is need for real professional education—that is, education similar to that given to law and medical students. These men first obtain their general college course and then attend a school where their entire time is given to professional studies. He thought in the future that we would have to depend upon the great engineering schools for producing the leaders. Professor Jackson approved of Mr. Alexander's plan and did not think it necessary to have the shop near the school. This matter could be adjusted. There should be closer co-operation between the manufacturers and the schools.

Professor C. A. Adams said that Mr. Alexander's scheme was being tried. The result remained to be seen. He did not take the same view of professional schools as did Professor Jackson, for at the law schools the students study cases and do not argue them; and at the medical schools they attend clinics, but do not operate. There is another difference which should not be overlooked. When the medical student is given his degree he must be equipped to be able to take the responsibility of his patients' lives, while the technical graduate is not required either to be responsible for life or for the success of the company with which he first connects himself. The plan advocated by Dr. Steinmetz is being tried at Harvard, as the students are allowed to take a general course in science or arts, obtaining the A. B. or B. S. degree in three years. After this they enter the Lawrence Scientific School as graduate students and obtain the engineering degree.

Professor Albert F. Ganz said that Mr. Alexander's plan would cut down the study of theory to three years by the elimination of laboratory work. This can not be cut out if Dr. Steinmetz's plan is to be followed. The first two years should be given to scientific instruction, and only in the third year should much time be devoted to practical questions. He asked President Stott whether he would like to have Mr. Alexander's plan applied in his power stations so as to give the students experience in the operation of large electric plants. To this suggestion Dr. Steinmetz interjected that the experience would certainly be good for Mr. Stott.

Charles F. Scott said that the discussion seemed to overlook the most important feature of the college education. The aim of this is to develop men of character and power, not to turn out men manually dexterous. There is need of great teachers to develop the proper type of man. The study of theory and practice must go hand in hand, and if the time lost in changing from one to the other is not too great the plan proposed would be good. The object of the college courses should be to turn out men thoroughly trained, and not graduates plastered with learning.

G. S. Dunn said that his experience had shown that the best graduates had usually had some practical experience. He thought that the students should come in contact with manufacturing methods before graduation. The discipline and training in the shop are good, and even if the men are kept at drilling name-plates for months, this is in a sense military training. If the man has any ability he will be able to pick up, while drilling, a great deal of useful information. He did not think it was necessary to have the college work and shop work as intimately mixed as Mr. Alexander's plan, and for this reason he was opposed to it. The college graduates are better than the other men, because of the discipline and experience which they have had. There would be some difficulty in applying Mr. Alexander's method generally, as it would be necessary for all factories in the country to take some of these students, while not all of them are in shape to do so.

E. R. Taylor said that one phase of the general problem should not be overlooked. At present we have good manual training schools in the cities. Such schools should be established in all the smaller towns, and they should be depended upon for selecting men for the technical colleges.

This completed the discussion on the educational papers, and then resolutions were adopted sympathizing with Dr. F. A. C. Perrine on account of his illness, which had lasted during the entire convention.

J. H. Finney spoke of the necessity for teaching the general public the great need for conserving the natural resources of the country. He quoted Speaker Cannon as saying recently that there is but one grain of wheat to the bushel of chaff of what the engineers have said. Mr. Finney said that if every member of the Institute, particularly those connected with local sections, would see to it that the true need for conserving our resources was appreciated by all with whom they had any influence there would soon be a good deal more than one grain of wheat to the bushel. He urged every member of the Institute to become a missionary in this work, and said he hoped that the engineers of the country would become the leaders in the movement.

The business of the convention having thus been completed, President H. G. Stott declared the convention finally adjourned.

ELECTRICAL CONTRACTORS' OPPORTUNITIES IN THE ILLUMINATING FIELD.[1]

BY GEORGE LORING.

What is the position of the electrical contractor in the field of artificial illumination and how may he extract profits therefrom? Lamp manufacturers devote their time to building illuminants with the highest attainable commercial efficiencies in hundreds of different sizes and styles to meet every conceivable lighting condition. Central stations generate and sell, at the lowest possible cost, the energy necessary to operate the lamps. The electrical contractor may profitably see that the public, the consumer of the lamps and the current, is made aware of every convenience and advantage which may be secured by their proper use, and is thoroughly posted as to the economical methods of producing a most satisfactory illumination at the lowest total cost. Lamp manufacturers, central stations, electrical contractors and the consumer should work in harmony. It is to their advantage to always have one another's welfare at heart.

HOUSE-LIGHTING SUGGESTIONS.

A plan, the carrying out of which gives much satisfaction and is also extremely economical to the consumer and creates business for the contractor, is the equipping of many parts of a domicile, whether it is or is not already electrically lighted, with fourteen-watt (three-candle-power) carbon lamps in addition to the larger ones which are always installed. Small lamps may generally be operated only when any of the sections in which they are located are not occupied. Larger lamps should naturally be out of service at such times. The utilization of fourteen-watt lamps will result in decreasing the number of rooms and halls now left in darkness after dusk, especially when the family is away for the evening; thus adding to the general comfort and appearance of the home and to the safety and security of the people and property therein.

As an example, showing how these small illuminants will work out, we will take a nine-room, three-story house which has a piazza in front. A fourteen-watt (three-candle-power) lamp equipped with Holophane reflector No. 2,677 and placed seven feet above the veranda, one foot out from the middle of the front door, will produce an illumination with an intensity of 0.2 foot-candle upon the centre of the door, making, in the majority of cases, the number thereon, if there is one, and there always should be, distinctly visible from the street. The fourteen-watt lamp will also sufficiently light, during the cold

Copper declined 5s in London with spot closing at £58 and futures at £58 10s. The local market was dull and unchanged with lake quoted at $12.87½@13.00; electrolytic at $12.62½@12.87½ and casting at $12.50@12.62½.

FIG. 1.

evenings, the piazza, the steps, and at least a portion of the path leading up to same. The imprint, shown in Fig. 1, with an illumination upon it of 0.15 foot-candle, may be read by the average person at a distance of eighteen inches. This will give an idea of the amount of illumination necessary to make clear from the highway a number upon a house.

There should also be located over the centre of the piazza a large lamp, such as a forty-watt tantalum or tungsten or a fifty-watt metallized-filament, which could be used when people are sitting upon the veranda in the summer and care to read or desire a higher illumination for any other purpose.

We will suppose that there is a hall, living room, library, dining room and kitchen on the first floor of this house. When any of these sections is not occupied, a fourteen-watt lamp could always be burning therein at a very low expense between the hours of dusk and the time the party retires.

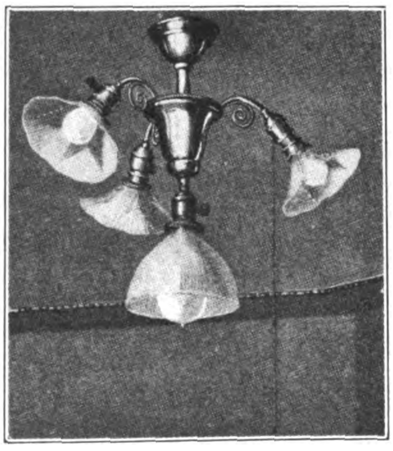

FIG. 2.—LIGHTING FIXTURE IN LIVING ROOM.

In the hall on the second floor a fourteen-watt lamp may be left burning all night and will also be found to give a sufficient light the majority of the time when it is necessary to have artificial illumination. The same may be said regarding a fourteen-watt lamp in the bathroom. In these places there should also be lamps of sufficient luminosity to furnish a higher illumination when necessary.

It costs only one-seventh cent an hour to operate a fourteen-watt lamp when current is ten cents per kilowatt-hour. It will therefore be seen that when the family is not using the first floor of this house, low-candle-power lamps, giving a surprisingly satisfactory light, may be operated in the hall, living room, library, dining room and kitchen for five-sevenths cent per hour, and may be in service in the hall and bathroom of the second floor at a cost of only two-sevenths cent per hour, and that one of these illuminants may be left on in the hall of the second floor all night at an expense of burning from 10 P. M. to 7 A. M. of one and two-sevenths cents.

We will assume another case where these low-candle-power lamps may be used to good advantage. Imagine a six-room apartment, consisting of a living room, two bedrooms, a hall thirty feet in length, dining room, den, kitchen and bathroom. Let the living room, dining room, hallway and bathroom each be equipped with a fourteen-watt lamp as well as a larger one. When any of these places is occupied, the large-candle-power lamp should be operated, the small-candle-power lamps being in service in the other sections. The bed chambers are off the hall and will naturally receive a small amount of light if their doors are left open. By following out this plan you have an illumination practically throughout the dwelling, and persons desiring to go from one place to another do not have to hunt around in the dark for a switch before making their way about. The home is also far more cheerful, as instead of certain parts being dark and gloomy, it is all comfortably lighted. The fourteen-watt lamps in the living room, hall and dining room may be left on any evening, when the home is temporarily deserted, at an expense of three-sevenths cent per hour. This is certainly a most cheaply acquired protection against theft.

In planning the lighting of a house utmost care should be used in placing lamps where they are most needed and employing only those which are efficient to the highest degree commercially and are equipped with accessories which will aid them in producing the necessary illumination at the lowest total cost. The accompanying illustrations show several inexpensive, highly efficient fixtures which may be used respectively in the living room, hall, dining room and a compart-

[1] Abstract of a paper read before the National Electrical Contractors' Association, Chicago, Ill., July 15.

ment, which, for lack of another name, we will call a den.

The living room is fifteen by twenty feet. The lighting fixture is hung from the centre of the ceiling, as is shown in Fig. 2. The lamp placed in a vertical position and suspended from the end of the fixture has its centre of luminosity eight feet above the floor. It is a forty-watt -tungsten, bowl frosted, equipped with Holophane reflector No. 6,046. With the tungsten lamp alone in service, the light directly from it produces an intensity of illumination upon the floor, at any place within a radius of seven feet from a point directly under the tip of the lamp, of from 0.3 to 0.4 foot-candle. This illumination is at least doubled on account of the light reflected from the walls, the reflecting coefficient of which is not less than 0.5. The direct intensity of illumination upon a book or table placed two and one-half feet above the floor, and located within a radius of five feet from a point under the tip of the lamp would be from 0.6 to 0.8 foot-candle. This illumination would be doubled by wall reflection. In other words, from this one lamp we receive a uniform illumination of high intensity over a large area. When no one is in the room the tungsten lamp is not operated and one of the fourteen-watt lamps, which will be seen upon the arms of the fixture, is lighted.

In the hall, placed as high as possible above the floor and suspended from the centre of the ceiling, is a fixture (Fig. 3). This is only a temporary device, but it demonstrates how easily a small and a large-candle-power lamp may be installed in one bracket. In this case the results are most satisfactory. The large lamp is a forty-watt tungsten, which gives an excellent light throughout the hall, the length of which is thirty feet. The small (fourteen-watt) lamp is used alone for low illumination, and at such times there is a sufficient light to allow everything in the hall to be plainly seen. It will be noticed that a Holophane reflector is used also with this lighting unit. The adoption of this accessory, when correctly located, increases the ordinary illumination of the lamps at least forty per cent.

Fig. 3.—Hall Light.

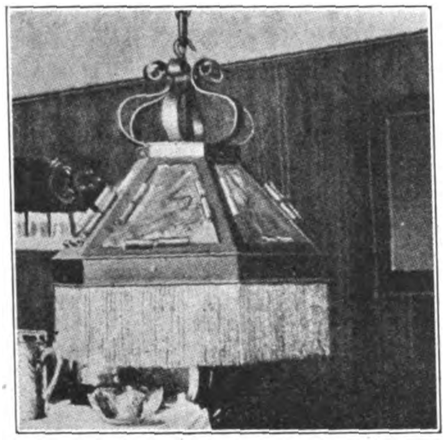

Fig. 4.—Dining Room Light Fixture.

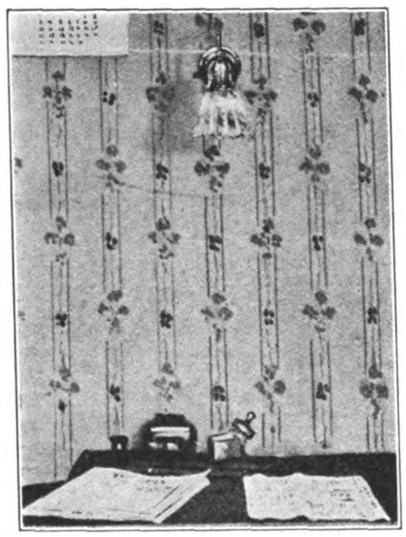

Fig. 5.—Den Lighting Fixture.

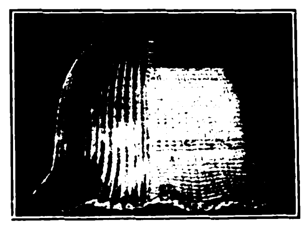

Fig. 6.—Special Reflector.

Fig. 4 shows a fancy dome used over the dining-room table. Enclosed within the dome is a fourteen-watt lamp and also a Holophane No. 6,045 reflector, used in conjunction with a forty-watt tungsten lamp and nearly hidden from view when parties are seated at the table. The reflector is employed for the purpose of preventing the great waste of light which would take place if all the upward rays from the lamp were allowed to come into contact with the glass of the dome. This glass would, on account of being highly colored and fairly thick, absorb about eighty per cent of the light which fell upon it and only part of the remaining twenty per cent would be reflected downward upon the table, whereas, by the use of the Holophane reflector the dome is made sufficiently bright, and the mean lower hemispherical candle-power of the tungsten lamp is increased forty per cent. In lighting this dining room, which is fifteen by eighteen feet, the intention is to have an illumination of as high intensity as is comfortable upon the covering of the table, which, by reflecting the light falling upon it will cause the rest of the room to be satisfactorily illuminated.

The den is seven by ten feet. The paper has a reflecting coefficient of about 0.6. Upon the centre of one of the narrow walls, and five feet above the floor, is a bracket supporting an eight-candle-power lamp and Holophane No. 245 reflector (Fig. 5). This reflector (Fig. 6) has one side consisting of prisms intended to reflect light and one side made up for diffusing light. It is the first side mentioned which is placed toward the wall on which the bracket is mounted. The result of the combination of the eight-candle-power lamp and the reflector is that the intensity of illumination upon a table located under the lamp is at least three foot-candles, and the candle-power in the direction of the wall nearest to the lamp is from only one-half to one-third of that in the direction of the opposite wall. The sum and substance of the whole matter is that by means of this reflector the horizontal light, which has only a short distance to go before lighting a part of the area to be illuminated, and the upward light, of which only a small amount is necessary, is curtailed, whereas the horizontal rays, which have to travel the greatest distance, as well as those in a downward direction, which are most useful, are increased, and last, but not least, the light is properly diffused. With few exceptions, I do not advocate illuminating by wall brackets. When such fixtures are already installed, however, they must be used to the best advantage.

Electrical contractors to-day have greater opportunities than ever for profitably working out lighting advantages in dwellings. On account of the introduction of the tungsten lamp and also most efficient reflectors, houses may be better illuminated, whenever high illumination is necessary, with a material decrease in meter bills. By causing those now using electric lights to be better satisfied they become stronger advertisers for electricity, which will mean more business for the central station and the contractor.

STORE LIGHTING.

If the standard of illumination in the dwelling of a business man has been raised there will be little difficulty in getting him to listen to a plan to change his store lighting.

When replacing carbon with tungsten lamps the endeavor should be made to install two forty-watt tungsten units for every three sixteen-candle-power carbon lamps displaced, provided the installation is as efficient as is possible with carbon-filament lamps. This method increases the illumination thirty-three and one-third per cent, and at the same time makes a net saving of twenty per cent on total lighting expense when current is six cents per kilowatt-hour. Net saving, in this instance, means that if a party using carbon lamps is receiving them free, the saving on lighting will amount to twenty per cent after deducting the price of the tungsten lamps, provided that current is six cents per kilowatt-hour.

If a person is illuminating his store by means of gas or gasolene lamps, his business should be secured through the medium of tungsten illuminants, installed either in units consisting of one lamp with proper reflector, or with tungsten clusters. Tungsten arcs containing either five sixty-watt or three 100-watt lamps will give a more satisfactory illumination than a Welsbach four-burner gas arc. With gas at $1 per 1,000 cubic feet, the expense of operating tungsten clusters will be no greater if current is seven cents per kilowatt-hour. Two 100-watt tungsten lamps will produce better results than a four-burner Humphrey gas arc. In this case the cost of lighting will be no greater with the tungsten lamps when current is nine cents per kilowatt-hour and gas $1 per 1,000 cubic feet. The initial lower mean hemispherical candle-power of a four-burner Welsbach gas arc is under normal conditions 281 candle-power. There will be a drop in candle-power, however, of twenty per cent within the first 100 hours and thirty-three and one-third within the first 300 hours of service. In other words, at the end of 100 hours the mean lower hemispherical candle-power will be 225, and at the expiration of 300 hours 188 candle-power. Under normal conditions, during its life, which averages 800 hours, a tungsten

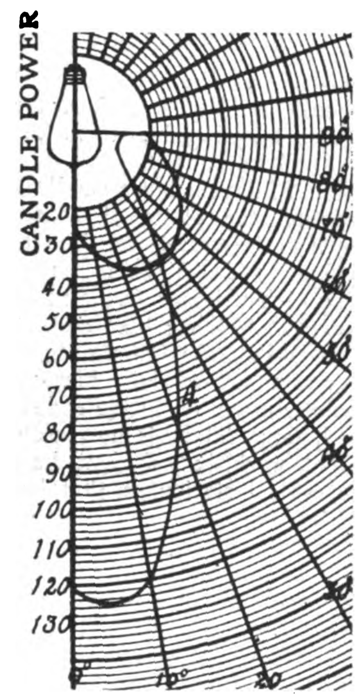

FIG. 7.—VARIATION IN DISTRIBUTION OF LIGHT WITH CHANGED POSITION OF REFLECTOR.

lamp does not drop more than ten per cent, and will therefore produce better illumination from the quantity standpoint and a clean pure light of superior quality.

GENERALITIES REGARDING LIGHTING BY ELECTRIC INCANDESCENT LAMPS.

It is most important, in order to do electric lighting justice, that the right reflectors be employed with the lamps and their relative position be correct. Untested reflectors and shade holders should not be used in a haphazard fashion.

The curves on Fig. 7 show the great variation in candle-power distribution and illumination resulting therefrom caused by simply changing the relative position of the reflector to the lamp.

Curve 1 is the candle-power distribution of a forty-watt, bowl frosted, tungsten lamp with a B2 crimped Holophane reflector in a given position. By bringing the reflector one and one-half inches nearer to the tip of the lamp a distribution such as is shown by Curve 4 is produced. This change of one and one-half inches in the relative position of this particular reflector to the lamp increases the candle-power in the direction of the tip 460 per cent. At all other angles up to approximately fifty-eight per cent the candle-power is greater than it was before. Between thirty-eight per cent and ninety per cent, however, it is materially lessened. Curves 1-D and 4-A (Fig. 8) show the intensities of the illumination received upon a horizontal plane within a radius of sixteen feet of a point directly under the tip of the lamp when it is suspended vertically over and has its centre of luminosity ten and twelve feet, respectively, above the plane illuminated, and when the candle-power distribution is the same as that shown on Curves 1 and 4 respectively. It will be seen that the intensity of the illumination as shown by curve 1-D is practically even upon a horizontal plane within a radius of five feet from the point directly under the lamp, and that if this radius is increased two feet the intensity of the illumination within that radius is very even, the ratio between the maximum and minimum being as 3:2. Curve 4-A, although depicting the intensity of illumination produced by the same lamp used with the same reflector employed to secure the illumination represented by Curve 1-D, and with all other conditions similar with the exception of the position of the reflector being altered one and one-half inches and the lamp being raised two feet higher above the objective plane, shows an illumination which is extremely uneven, the ratio of the intensity of the illumination at the point on the plane directly under the lamp compared to that

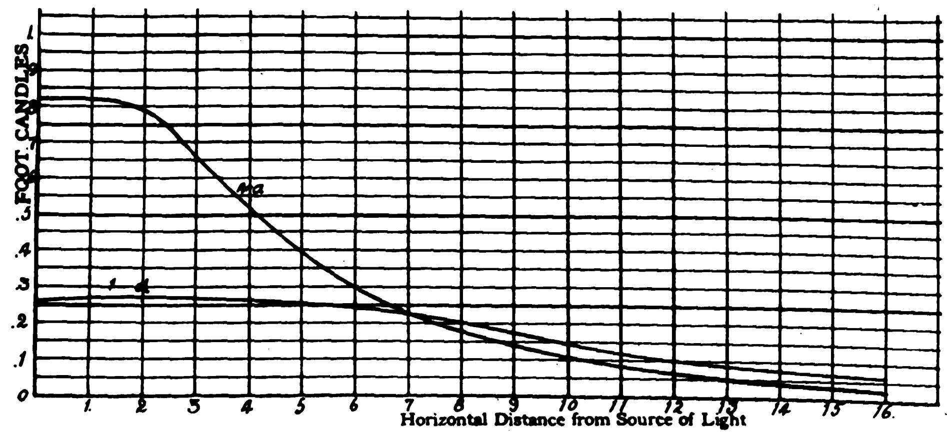

FIG. 8.—INTENSITY OF ILLUMINATION ON HORIZONTAL PLANE.

upon the plane eight feet from the point just mentioned being as 100 : 24. Lighting units having a candle-power distribution as shown by Curve 1 should be located with the distance between them equal to 1.2, 1.5, or two times their height above the objective plane to produce an even illumination upon it.

Fig. 9 represents a plane to be illuminated by lamps located with their centres of luminosity ten feet above it, the distance between them being fifteen feet. The reflectors upon the lamps are placed in such a way that each lighting unit has a candle-power distribution similar to that shown in Curve 1, Fig. 7. The intensity of illumination upon the Plane A-B, Fig. 9, when only two lamps, namely, those directly over *a*, *b* are in service, is from 0.31 to 0.4 foot-candle. The intensity of illumination upon Plane A-B, when the lamps over *a*, *b*, *c*, *d* are in use, ranges from 0.37 to 0.44 foot-candle. The intensity upon Plane A-B, when lamps over *a*, *b*, *c*, *d*, *e*, *f*, *g*, *h*, *i*, *j*, *k*, *l* are operated, is from 0.54 to 0.61 foot-candle. The illumination upon X produced by the illuminants over *a*, *b*, *c*, *d*, *e*, *f*, *g*, *h*, *j*, *k* is 0.576. The illumination upon Plane Y-Z, from lamps over *s*, *y*, *r*, *z* and *c*, is from 0.4 to 0.5 foot-candle. The area of the plane illuminated is 5,644 square feet. Total watts used in lighting it are 1,220; watt per square foot, 0.21, and the watt per average foot-candle, 0.36. No reflection from sources other than the reflectors used with the lamps has been taken into consideration in figuring the foot-candles upon the objective plane.

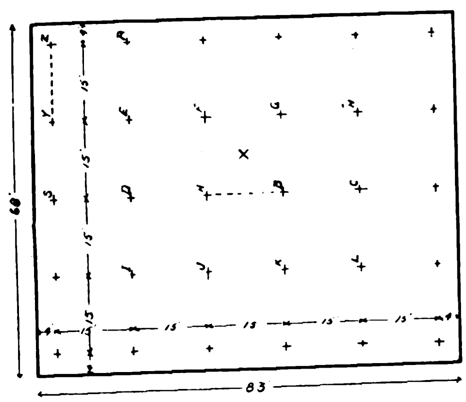

Fig. 9.—Illumination from Various Light Sources upon Horizontal Plane.

It should be the aim of every one endeavoring to produce satisfactory illumination to have its intensity, with few exceptions, highest and apparently equal and uniform upon the objects most necessary to be seen. All surfaces other than those of such objects, being of secondary importance, should, if possible, be more lowly and to a certain extent unevenly illuminated, thus forming a background for that which it is desirous to make most conspicuous and eliminating the possibility of flatness in the lighting scheme. In the majority of cases the illuminants themselves should be of such a character and so located and equipped as to make their presence absolutely unfelt.

The sale of lamps is but a small part of the work of the electrical contractor. Ofttimes it is impossible for him to sell them owing to the lighting companies furnishing carbon lamps free and disposing of tungstens at less than cost. Even when this is the case the profits of the contractor may be materially increased by giving proper attention to the lighting of stores or homes. There is no reason why he can not work in sufficient harmony with the central station so that he may secure orders for practically all materials for furnishing light, with the exception in some cases of the lamps.

The contractor should give to his customers the illuminants which are the most economical (based on lamp and operating cost combined), not necessarily the longest lived. After the lamps are sold the contractor should endeavor to see that they are properly placed and most efficiently equipped. Give a man the best which can possibly be obtained for his money, show him how he can add to his personal home comforts or increase his business through the proper equipment and use of many lamps, which at the present time he does not understand, and it will be found that the lighting end of the business, which has probably had very little attention, will be bringing in a most profitable revenue.

Condemns New York City Fire-Alarm System.

The report of the commissioner of accounts, dealing with conditions in the New York city fire department, condemns the present fire-alarm system as obsolete and a menace to the city and recommends that it be replaced by thoroughly modern apparatus.

The estimated cost of the proposed new fire-alarm system, as given in the report, is $2,680,000.

The danger that the city's fire-alarm system might be entirely put out of commission in event of a fire or other serious mishap at fire headquarters, where the main or central office is located, is pointed out in the report.

In addition to recommending an up-to-date alarm system the commissioner, to obviate the danger at headquarters, suggest that the "central" alarm station be installed in the southern part of Central Park, or, if that should prove objectionable, in the neighborhood of Fifty-ninth street.

Experiments on a Directive System of Wireless Telegraphy.

A. Tosi on May 22 read before the London Physical Society a joint paper by himself and E. Bellini on the above subject, in which they described the results obtained in the course of their work upon a further development of their original directive system.[1] In their earlier method it was not possible to say from which side of the receiving station the transmitted waves arrived, for though the radiation was practically confined to the plane of the aerial system, it was emitted equally in the opposite direction to that desired.

In the new unilateral system, it is said, the waves are sent in a single direction only, and the problem of getting rid of the backwardly extending radiation has thus been solved. The method adopted consists in superposing a bilateral directive system, as previously described, upon an ordinary or vertical antenna system. Since the two half-diagrams of the directive aerial are opposed in phase, it follows that when the two systems (directive and vertical antenna) are simultaneously excited and in phase, the one half of the directed radiation will add itself to, and the other half subtract itself from, the radiation due to the vertical-antenna system. The diagram of the vertical-antenna system being a circle, the resultant diagram of the superposed systems will, for the case where these are in phase as regards excitation, be a cardioid whose maximum radius vector is double that of the diagram of the directive system alone. Since then the directive system is able to vary the direction of its maximum emission by means of the radiogoniometer, it follows that by moving the position of this latter it is possible to shift the direction of the resultant emission represented by the cardioid, in a corresponding manner. Several energy diagrams obtained by means of the thermogalvanometer are reproduced in the paper, and these show that, even where the excitations are not exactly in phase, the only result is a slightly less good diagram. Diagrams of the scheme of connections employed during the taking of the energy diagrams are also given.

The same principle of the superposition of the two systems has been applied to the case of the reception. In this case a phase displacement of ninety degrees in the excitations is produced in a suitable manner and in this way, when the pointer of

[1] See Electrical Review, May 9, p. 727; July 18 p. 101.

the radiogoniometer is directed, say, toward the transmitting station, the reception is a maximum, while when turned at 180 degrees from this it is a minimum, or zero. Diagrams of received energy and of the connections employed are also given in this case.

The system of unilateral directive wireless telegraphy now described by the authors is of special interest owing to the facility with which it is possible to change over from one system to the other, thus, from the ordinary vertical-antenna system to the bilateral directive or the unilateral directive, or *vice versa*. The aerial arrangements, moreover, remain exceedingly simple. When a message from a station of unknown position is expected, the vertical-antenna or ordinary system would be employed; on once effecting reception, one can pass to the bilateral or unilateral directive system and thus determine the direction and on which side the transmitting station lies, at the same time making oneself independent of other transmissions. In the same way, with the transmission, the vertical antenna would be employed for calling up an unknown station or for simultaneously sending to several stations; on once getting a reply the operator can then readily determine the position of the receiving station, with the aid of the unilateral system, and thenceforth will transmit solely in that direction.

The authors further called attention to the advantages which such a directive system offers in the case of the commercial services, as well as for military and naval purposes.

A discussion followed in which Dr. J. A. Fleming, Dr. W. H. Eccles and W. Duddell took part.

Dr. Fleming, after congratulating Bellini and Tosi on their skill and inventiveness in the investigations, said that the experiments confirmed, in many ways, his own theory of the operation of a bent antenna as employed by Mr. Marconi. When Marconi described his experiments on directive telegraphy before the Royal Society in March, 1906, he gave no theory in the matter. Dr. Larmor pointed out then that an antenna partly vertical and partly horizontal was equivalent to the sum of a magnetic oscillator and an electric oscillator. Shortly after, Fleming went more carefully into the matter mathematically and showed that the observed effects could be accounted for on that theory. Both Marconi and Fleming had obtained by the same methods as Bellini and Tosi the same type of pear-shaped radiation curves by combining the effects of closed and open oscillators. Although Dr. Mandelstam had lately criticized this theory there did not seem to be sufficient grounds for objecting to it. Marconi had long employed directive antennæ in Poldhu and Clifden power stations, and had also given demonstrations showing that the position of ships out of sight could be located by means of such receiving directive antennæ. Nevertheless, Bellini and Tosi had worked out extremely ingenious arrangements for determining the direction of the radiant point without moving the antennæ themselves. Fleming said that he had also shown that, having the power to locate the radiant point, two stations equipped with such antennæ at a known distance apart could, by simultaneous observations, determine also the distance of the radiant point, and this might become important in connection with marine work.

Dr. W. H. Eccles warmly congratulated the authors upon their original and beautiful method. On this method, by merely rotating a small coil of wire on the table, a fixed aerial directive system of any size was made to do what could otherwise only be done by turning the whole system of aerial wires in azimuth. The essence of the system was the piece of apparatus styled the radiogoniometer, which, by causing appropriate component radiation from two fixed wire triangles set at right angles, brought about a resultant radiation in any direction desired—just as if a virtual aerial of the full size of the fixed aerials were being rotated in the air. Someone had compared the result so achieved with that obtained by Marconi's well-known arrangement of a number of fixed bent antennæ with their horizontal portions directed from a centre to various points of the compass.

The looped aerials used by the authors did not seem to the speaker to be the best kind of radiator for utilizing the principle they had developed. The radiogoniometer would prove to be capable of giving excellent results with two fixed antennæ of the best type set at right angles, one, for example, in the meridian plane and the other in the east-west plane. The two looped aerials of the authors may each of them be assimilated to a pair of vertical antennæ emitting waves of 180 degrees phase difference, and with the assumption that for a single vertical aerial the inverse square law holds for the propagation of electrical effects from a single aerial, the speaker showed by aid of the ordinary equation of wave-motion that a looped antenna obeying the condition stated emitted two waves of equal period, of phases differing ninety degrees and 180 degrees, respectively, from the phase of the radiation from either side of the loop, and of amplitudes having a ratio proportional to λ/x. This means that one portion of the resultant radiation obeys an inverse square law and the other portion an inverse cube law; the latter portion is the more important of the two when the distance x is small; the former is the more important when the distance x is much greater than the wave-length λ. This explains why Dr. Fleming's measurements of the radiation from closed oscillators, which were carried out at short distances, gave small promise of powerful propagation to a distance, and why Bellini and Tosi had found as a fact that good propagation occurred to great distances.

As regards the phases of the two portions of the radiation, the important portion for wireless telegraphy, namely, that obeying the inverse square law, was ninety degrees out of phase with the near side of the loop; and thus it is clear that the vertical aerial the authors had used to cancel the radiation to one side of the sending station, must for that purpose emit radiation ninety degrees out of phase with the near side of the loop. Bellini and Tosi had reached this conclusion in the course of their experiments.

After eliciting that the power-supply to the primary of the induction coil for the Dieppe-Havre experiments was 500 watts, Dr. Eccles concluded by remarking that the authors were worthy of special congratulation because in their method of unilateral transmission by phase and intensity adjustment of several radiators they had eluded the difficulties of managing the phases that had apparently baffled F. Braun when he was using the same principle.

Mr. Tosi, in reply to Dr. Fleming, stated that Braun's cardioid diagram was a theoretical diagram only; the method had not succeeded and no actual diagram obtained experimentally had ever been shown.

Referring to the similarity which Dr. Fleming said the pear-shaped diagram of Marconi bore to the authors' diagrams, Mr. Tosi could only say that they had purposely shown some bad diagrams as well as some good ones. The good diagram of Marconi's corresponded to the authors' bad diagram. With the Marconi horizontal aerial it would, moreover, be necessary, as Dr. Eccles had pointed out, to employ 360 such wires to obtain an accuracy in locating the bearing of the radiant point equal to that secured with the system now described. Further, if the emitted energy is actually represented by Marconi's pear-shaped diagram, it is difficult to understand why the transatlantic messages from Clifden to Glace Bay are readily picked up off the Algerian coast, at right angles to the line of transmission.

In reply to Mr. Duddell he said that the wave-length of the waves employed was from 350 to 400 metres.

REVIEWS OF CURRENT ENGINEERING AND SCIENTIFIC LITERATURE

Town Refuse as Fuel for Generating Electricity.

At a recent meeting of the Incorporated Municipal Electrical Association of Great Britain an address was delivered by Herman Talbot upon the conditions affecting the operation of electric generating stations. During this the speaker touched upon the operation of refuse destroyers in conjunction with generating stations and referred particularly to the performance of the Eastcroft destructor at Nottingham, England, which destroyed 28,302 tons of refuse last year, producing therefrom 1,069,885 kilowatt-hours. The wages of the men in the destructor plant amount to $10,730. The output averaged 240 kilowatts. As, however, this output could have easily been supplied from the generating station itself, the wages paid to the operators were unnecessary from the point of view of the station. The cost per kilowatt-hour thus produced was about 0.96 cent, which would more than pay for the additional steam which the load would have used. The destructor runs from fourteen to eighteen hours a day with a load-factor of twenty-eight per cent and generated nine per cent of the total electrical energy supplied to the city. This seems a creditable performance, but it must be remembered that the destructor station of necessity supplies the cheap units at the bottom of the load curve and leaves to the main station the task of supplying the expensive ones at the top, with a consequent reduction of the latter's load-factor. It thus seems, from the station point of view alone, that a destroyer plant is not a desirable auxiliary, but since the destruction of refuse by burning is the most effectual method, and since this cost of burning must be borne whether the heat be utilized or not, it would be a pity not to utilize it even if in so doing the electrical system contributes indirectly toward the expense of the destruction.—*Abstracted from Mechanical Engineering (London), July 3.*

Motor-Driven Wheatstone Transmitter.

One of the valuable factors of the Wheatstone telegraph system is the ability which it gives of rapidly sending messages over a single wire. Thus, in case of breakdown of a line, the entire office force may be set to punching messages and transmitting them at four times the speed over the one or two wires which may remain in service. The system as in use to-day has altered but little since it was introduced by its inventor. A number of improvements might be suggested, one of these being the substitution of a keyboard perforator and another a better method of driving the transmitter. The latter is usually driven by clockwork, which necessitates continual rewinding, thus disturbing the attention of the operators. This method is somewhat inflexible, as it is not easy to change the speed of the transmitter when this becomes desirable. The substitution of a small electric motor for the clockwork drive was suggested some years ago, but it does not seem to have been applied satisfactorily. In this article, C. C. Vyle and E. V. Smart describe a motor drive which they have developed for this purpose. The motor is rated at one-sixteenth horse-power and operates at 110 volts. It is series wound and has a German silver plate fixed at one end of the axle. This is made rigid and is used as a friction plate. On the front of the friction plate rests the edge of a friction disc, consisting of two thicknesses of compressed hide held tightly between two metal discs. The hide only touches the friction plate. A ball is held by springs against the end of the armature remote from the friction plate, forming a thrust-bearing. This holds the plate firmly at constant pressure against the disc. On the axle of the friction disc is the gear driving the transmitter. To vary the speed of driving, the friction disc is traversed across the plate, the change in speed being continuous. By placing the disc a little out of line with the centre a slight force tending to move it toward the centre of the wheel is set up, so that it is only necessary to provide a screw holding the disc away from the centre. This arrangement gives any desired speed and the series characteristics of the motor enable it to run up to its operating speed quickly.—*Abstracted from the Post Office Electric Journal (London), July.*

Wave-Form Analysis.

A discussion is given here by P. M. Lincoln of the Fischer-Hinnen method of analyzing wave forms. This system is based upon the following theory: If three ordinates of a sine wave be erected 120 degrees apart, their algebraic sum is zero if the curve be a pure sine wave. The same is true for any five ordinates, provided the interval between them be seventy-two degrees. In the same way it holds for *n* ordinates, provided the distance between them be 360 degrees divided by *n*. If a third harmonic wave be imposed upon this sine wave the algebraic sum of three ordinates taken 120 degrees apart is no longer zero, but is equal to three times that of the ordinates of the third harmonic. One ordinate of the third harmonic may thus be determined, provided no multiple harmonic of the third be present. They may, however, be allowed for by a suitable correction. In the same way an ordinate of the fifth harmonic or of the seventh may be obtained. The method of determining these harmonics consists then in finding two ordinates of each, ninety degrees apart. These values are sufficient to determine the complete curve of each harmonic. The ninety degrees difference between the two values must be measured in terms of the harmonic considered. Knowing these two values any maximum value is found by taking the square root of the sum of the squares of the two. The tangent of the arc subtending the angle representing the difference in phase between the harmonic and the fundamental, measured in terms of the harmonic, is given by the ratio of the two ordinates which have been found. The sign of this ratio determines the direction in which the harmonic crosses the axis of abscissas. Mr. Lincoln gives a general formula which can be used in determining any harmonic by substituting the proper values as measured from the wave being steadied. In applying this method to electrical work the even harmonics are usually absent and need not be looked for. If the wave is symmetrical about its maximum ordinate, the solution is somewhat simplified, as this means that all harmonics cross the base line at the same point as the fundamental. Under this condition but one set of ordinates need be determined.—*Abstracted from the Electric Journal (Pittsburg), July.*

A Simple Duplex Telegraph System.

A simple duplex telegraph system—that is, a system enabling two messages to be sent simultaneously in the same direction over one wire—is described here, which, in addition to its simplicity, is independent of the weather conditions, there being no necessity to balance up an artificial line against the varying resistance of the transmitting line. The system requires, at the sending station, two ordinary Morse keys connected in independent circuits between the line and the ground, each circuit including a battery. A third circuit connected in parallel with the two ground connections of the keys contains a resistance and a third battery more powerful than either of the other two. At the receiving station there are two receiving instruments, one of which is a simple sounder operated by a polarized relay responding to positive current impulses. The second is a similar sounder, connected, however, in the opposite direction, so that it responds only when its local circuit is broken. This may be accomplished by either of two relays, both of which are polarized. One responds to weak negative current impulses, and the other to strong positive impulses. In operation when either key of the sending station is closed it sends a relatively weak positive or negative impulse over the line, according to which key is depressed, and this impulse causes the corresponding relay at the receiving station to respond. Should both keys be depressed at the same instant this will send a strong positive impulse over the line, actuating, of course, the relay which responds also to weak positive impulses and that one in the second receiving circuit which responds only to strong positive impulses. Under this condition both sounders at the receiving station would respond. To secure operating conditions it is necessary to have the battery which comes in operation when both keys are depressed sufficiently powerful to operate both relays. When one key alone is depressed this battery does not send an impulse over the line, because at that moment it is short-circuited through a resistance and the other key, the potential thus thrown upon the line being insufficient to overcome the opposed working battery.—*Translated and abstracted from L'Industrie Électrique (Paris), June 25.*

Portable Type of High-Frequency Alternator.

A discussion is given here by R. A. Fessenden of a small high-frequency dynamo, built for use in wireless signaling. The machine was constructed to give an output of one kilowatt, but it was found that it could carry considerably more. It is approximately twelve inches high, and, including the steam turbine which drives it and the governor, is nearly three feet long. The diameter of the rotating field disc is six inches; that of the steam turbine disc is three and one-half inches. The original design was for a machine developing 250,000 cycles a second, but as it had been found that a frequency below 90,000 would give a much better range of transmission during the day the design was altered so as to give 100,000 cycles. The machine will normally run in the neighborhood of 75,000 cycles a second. For the lower frequency a steam pressure of 100 pounds per square inch is used in the turbine. To obtain the highest frequency the steam pressure required is about 135 pounds. The specifications call for constant operation for twenty-four hours without attention and this test has been passed successfully. The oiling arrangements are automatic. At present the alternator gives about 225 volts on open circuit, at 75,000 cycles, with an armature resistance of five ohms. The available output of the machine is about two and one-half kilowatts at this frequency. The excess of this output over what had been expected is due to conservative design and considerably smaller friction and windage losses than had been anticipated. These two losses aggregate about three kilowatts, but they may probably be reduced to one-half this amount by slightly modifying the design. Theoretically this machine can develop four kilowatts at the high frequency, but the field shaft is too small to carry this load. The machine is of a double-armature type, there being 300 coils on each armature; the field has 150 teeth. The two field air-gaps are approximately one-sixteenth inch in length. The machine runs absolutely without vibration. For speed regulation it has been found impossible to depend upon the governor of the usual type. For this purpose the Fessenden resonance speed indicator is employed. The method of controlling the generator consists in connecting it in a circuit attached to the antenna. This circuit is tuned to about one-twentieth of one per cent higher than the desired frequency. In this circuit is a dynamometer having two contacts which govern an electrically controlled throttle valve in series with a sensitive reducing valve in such a way that if the frequency increases one-twentieth of one per cent, the needle touches one contact and cuts down the speed. If the frequency falls by the same amount, the reverse operation takes place. By using a larger amount of inductance in this circuit, an air condenser and a low-resistance dynamometer, theoretically the speed might be kept constant within approximately one-fiftieth of one per cent; but this close regulation has not been obtained in practice. The best so far secured is one-twentieth of one per cent. By this arrangement any desired frequency is quickly obtained by setting the indicator to the proper value when the circuits automatically alter the speed for the dynamometer until the desired frequency is reached. In special cases a safety device, consisting of an additional tuned circuit arranged so as to be in resonance at a frequency about five per cent higher than that of the governing circuits, is used. Should the frequency reach that resonant with this circuit, a signal will be given or the dynamo automatically stopped. The alternator is used for transmitting signals by running it at that frequency which produces resonance in the receiving circuit. When a signal is to be sent a key is depressed which alters the frequency of the alternator about one-twentieth of one per cent, thus producing beats in the receiving instrument. This change in frequency is accomplished instantaneously by electrical means, it being, of course, impossible to change mechanically the speed of rotation. The advantage of this method is that the machine is operated continuously, generating waves of the same intensity which at their high frequency have no audible effect on any neighboring station. For a signal to be received, the receiving circuits must be adjusted so that these beats due to a slight difference in frequency will be produced.—*Abstracted from the Electrician (London), July 3.*

London Tube Finances.

The English Chancery Court on July 16 sanctioned the scheme for the readjustment of the finances of the Underground Electric Railway Company as approved by the shareholders at a meeting held in London, May 11. This plan provides for the issuance of various bonds aggregating $46,000,000, the amount necessary to this end.

INDUSTRIAL SECTION

ILLUSTRATED DESCRIPTIONS OF NEW AND STANDARD ELECTRICAL AND MECHANICAL APPARATUS

The International Electric Meter Company's Measuring Instruments.

Within the last few years there has been developed by the International Electric Meter Company, Chicago, Ill., a high-grade line of alternating and direct-current voltmeters and ammeters. This business was started in a very small way by first placing upon the market a direct-current, switchboard-type voltmeter and ammeter. This line of instruments to-day consists of approximately twenty-five different types of measuring instruments, which include switchboard and portable voltmeters and ammeters, besides pyrometers, automobile and special school laboratory types of instruments. Illustrations of some of these are shown herewith. New features are continually being developed and placed upon the market.

Two distinct principles are now used. One exclusively for alternating current, which is an induction meter, known as the "repulsion" type, and one exclusively for direct current, of the Deprez-D'Arsonval or permanent-magnet type.

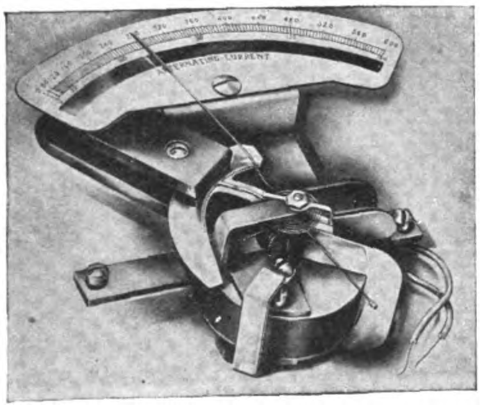

Fig. 1.—Alternating-Current Instrument, Ready to Mount in Case.

Fig. 2.—Alternating-Current Instrument Complete.

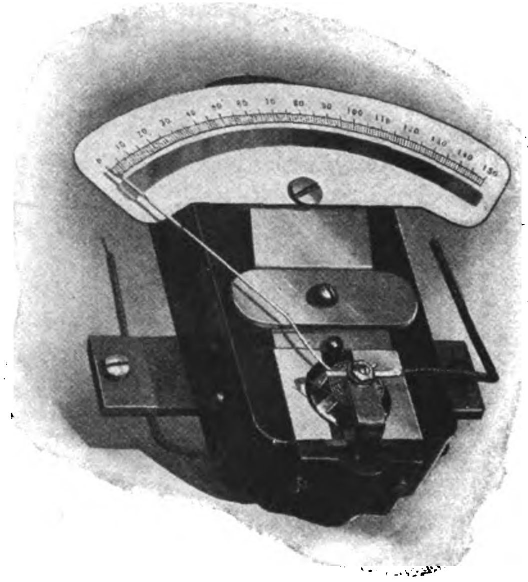

Fig. 3.—Direct-Current Instrument, Ready for Mounting in Case.

The "repulsion," or alternating-current, type is in fact a small transformer, with two secondary coils short-circuited; one being free to move. This instrument has a closed magnetic circuit of laminated iron and the torque is produced by the direct repulsion of the current in the primary upon the secondary; their currents being nearly in opposite phase. The moving element is extremely light and rigid, and is quick to respond to slight changes in current strength. The oscillation of the moving parts is magnetically dampened and swings in the best grade of sapphire bearings. Fig. 1 represents the alternating-current movement ready for mounting in the case. Fig. 2 represents the complete instrument.

Fig. 4.—School Laboratory Glass-Front Instrument.

Fig. 5.—Direct-Current. Portable Volt-Ammeter.

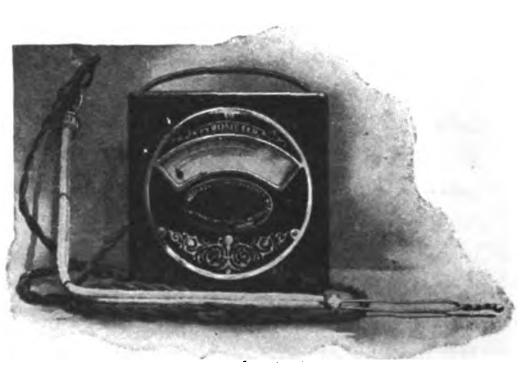

Fig. 6.—Electric Pyrometer.

The principle of the direct-current movement is well known and used by most of the manufacturers of high-grade instruments. The mechanical features, however, vary considerably. The International direct-current instrument is well balanced upon its support in the case, and parts may be readily removed for repairs. Fig. 3 represents the direct-current movement ready to mount in case. Fig. 4 represents the school laboratory glass-front instrument.

Fig. 5 represents a direct-current portable volt-ammeter, and Fig. 6 represents an electric pyrometer.

The shop and laboratory equipments are complete with special machinery and testing instruments necessary for the manufacture of high-grade apparatus.

The men employed for manufacturing, assembling, testing and inspecting the

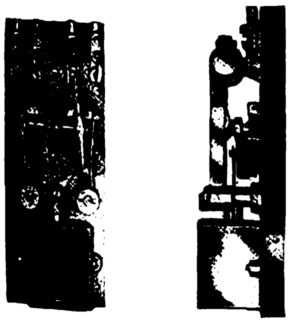
International instruments have had long experience in the work for which they have been selected.

The sales of this company are made direct to the user or through the jobber, whichever is more convenient for the customer. The electrical jobbers have been quick to learn that the International line of instruments is one especially desirable for them to handle. Shipments are made promptly and treatment secured from the International company is courteous and fair. The men in charge of the International Electric Meter Company's affairs are William W. Cheney, Jr., president; August Benson, secretary; Julian S. Jackson, sales manager, and John M. Lea, chief engineer.

Darrin Magnet Switches.

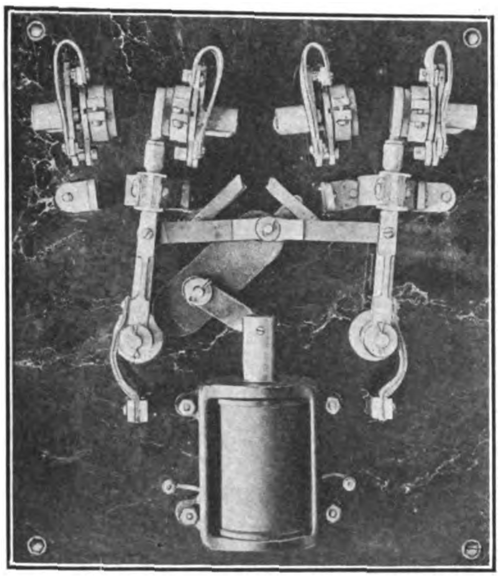
The Automatic Switch Company, 131 Liberty street, New York city, has developed a magnet switch which is of considerable interest to contractors. This is a small two-pole Darrin magnet switch with a capacity of twenty-five amperes. The Darrin magnet switch fills the requirement of a switch which will work equally well on direct or alternating current, in which the magnet circuit carries current only for an instant during the actual operation of the switch. The switch can be placed with carbon and copper butt contacts for motor control, or with knife-blade contacts for lighting work.

One of the illustrations shows the type DMS "300-2 R" reversing switch, and the other illustrations show the type DMS "25-2," front and side views. The reversing type switch has a capacity of 300 amperes.



Front and Side Views of Darrin Type DMS 25-2 Reversing Switch.

By the peculiar construction of the magnet circuit in these switches the switch can be actuated either on or off or from one position to the other without carrying current in the magnet circuit longer than necessary to throw the switch. As the magnet circuit is opened on contacts on the switch itself, there will be no arcing at the controlling point. This type of switch can thus be controlled by thermostats, pressure regulators or with ordinary push-buttons, which have no quick-break features.



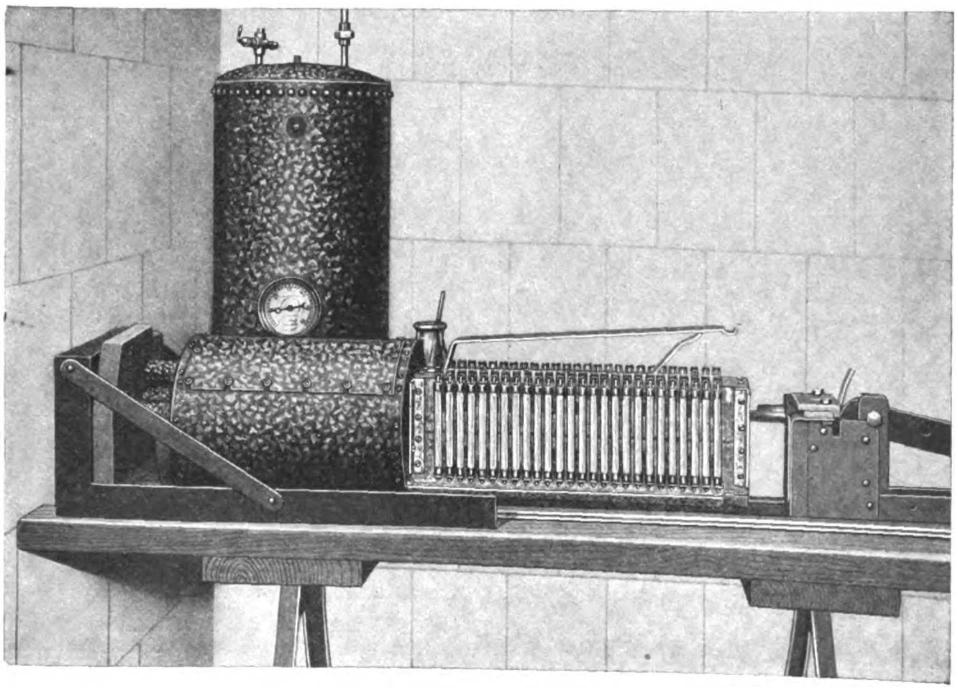
Darrin Type DMS 300-2 R Reversing Switch.

The switch is especially well adapted to the control of heavy lighting circuits from various remote points, and will be supplied, when so ordered, with magnetic blowouts at a slight additional expense.

All switches of seventy-five amperes or greater capacity continuous rating are provided with flexible carbon contacts so as to insure a level surface on closing. In the smaller sizes the contact arms are provided with springs to effect the same result.

Moisture-Proof Pole Cable Terminals and Junction Boxes.

The accompanying illustration shows an interesting corner of the factory of Frank B. Cook, Chicago, Ill., where junction boxes and non-pothead terminals are tested for leakage. Special care is exercised in the construction and assembling of these types, and every precaution is taken to render them air-tight. The final inspection consists of testing each piece of apparatus under ten pounds air pressure, this being accomplished by connecting the piece to be tested with the machine shown in the illustration. The terminal or junction box is placed on a special frame, the air pipe being placed in the self-soldering nozzle with which these types of apparatus are equipped, and this nozzle is forced against a piece of solid rubber through which the air pipe extends. When the pressure is turned on the gauge registers any decrease of pressure in the tank, thus detecting any leakage. A further test is to cover the joints with soapy water, the slightest leak causing a bubble to form at the point. These types of Cook apparatus are guaranteed to be moisture-proof.



Testing Cook Waterproof Terminal Head.

The Stave Flaming Arc Lamp.

The Stave flaming arc lamp, an illustration of which is shown herewith, has been built very carefully, taking advantage of a very valuable experience in the operation for many years of alternating-current arc lamps, and embodying many features of more than ordinary merit. The control of the lamp electrodes is attained by rotating aluminum discs in either direction, accordingly as either a series or a shunt magnet is excited. This control is ideal, three full revolutions of a disc corresponding to a feed of one-sixteenth inch.

Stave Flaming Arc Lamp.

The upper part of the lamp containing the regulating mechanism is sealed, and it is stated that in many years of operation it has not been necessary to break this seal to effect repairs. Each lamp is equipped with an internal resistance, so that it is immediately ready, burning two in series, for use on 115-volt circuits. Each lamp automatically takes care of its own voltage, and all will burn at forty-five volts.

All interior connections are made with fine stranded copper conductors, insulated with glass beads, which are impervious to fumes or heat, and all current-carrying parts are insulated by mica and air.

In the construction of the electrode holders, a substantial and easily accessible thumb-nut is used.

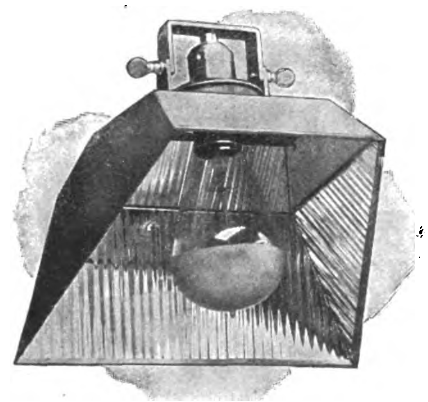
The lamp is furnished in several finishes, the brass, copper and nickel finishes being especially adaptable for the lighting of stores, halls, etc.

Theodore Stave, president of the Stave Electrical Company, manufacturer of this lamp, has been very successful in popularizing it, some 10,000 being in use in Europe, and is now making his headquarters at No. 1 Madison avenue, New York city.

Wheeler Reflector Company's New Fixtures.

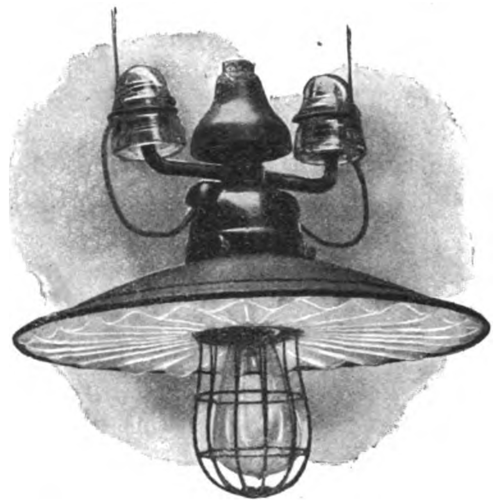
The Wheeler Reflector Company, 156 Pearl street, Boston, Mass., has placed on the market two new fixtures adapted especially for use with tungsten lamps.

The Wheeler tungsten adjustable window reflector No. 65 is a corrugated mirror-lined reflector attached to the stem of a fixture above the socket by a hinged holder which permits adjustment at any angle, the lamp remaining in a vertical position. With a 100-watt tungsten lamp this fixture distributes ample light over the average show window. The upward radiated light is all reflected down, that from three sides forward and down and that from the remaining side is radiated horizontally without interference.



Wheeler Tungsten Ajustable Window Reflector.

The Wheeler tungsten street fixture No. 770 consists of an eighteen-inch porcelain-enameled steel reflector fluted to give the most effective candle-power distribution and protected by a copper or painted steel hood attached to a cast holder. The illustration shows malleable iron cross-arms supporting pony glass insulators in a vertical position, but where desired these may be cast in one piece with the holders, so that the insulators may be held at right angles to the stem. The mica insulating joint is designed for high-tension circuits and will stand a break-down test of 34,000 volts. The important feature of this fixture is the reflector which, besides being fluted and slightly convex, is adjusted at such an angle with relation to the filament and of a sufficient diameter to intercept the light rays radiated in the direction of the base, that with a forty-candle-power lamp the light distributed shows a curve beginning at about forty-five candle-power at the horizontal, increasing to fifty candle-power at nearly every angle from twenty degrees to forty degrees below the horizontal, then gradually dropping to forty candle-power at sixty degrees and twenty-five candle-power in the direction of the tip.



Wheeler Tungsten Street Fixture.

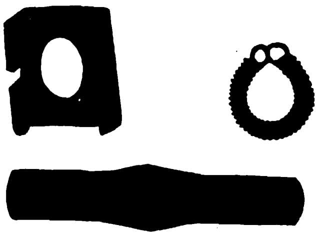
"Verus" Conduit.

Arthur P. Pierson, 23 North Juniper street, Philadelphia, Pa., is introducing a new non-metallic, flexible conduit, which is designated as "Verus." This conduit is made of narrow tubular sections of asbestos fibre treated with moisture-proof insulating compounds which have the properties of withstanding a fire test of about 400 degrees centigrade. The conduit is protected on the outside with an additional tubing, and the whole has a woven cover over all, treated with standard insulating compounds approved by the National Board of Fire Underwriters. This conduit not only has a fireproof interior, but a fireproof exterior as well.

These conduits are being manufactured by the Protecus Electric Manufacturing Company, of Allegheny City, Pa., for which Mr. Pierson is general sales agent.

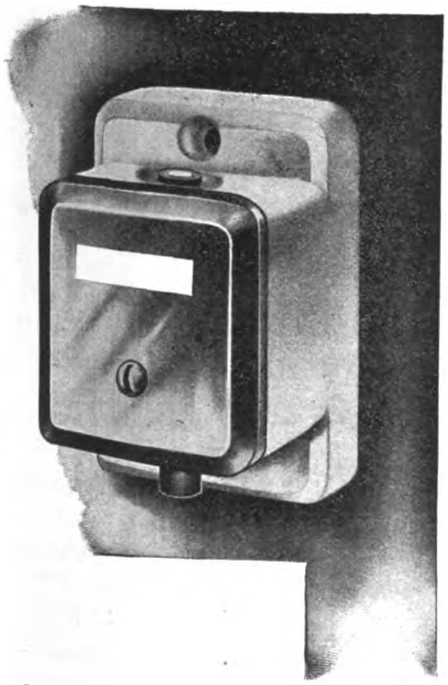
Cutler-Hammer Push-Button Specialties.

One of the most interesting, and doubtless a device which will be conceded revolutionary in its nature, is the push-button specialty which the Cutler-Hammer Manufacturing Company, Milwaukee, Wis., has placed on the market. This line includes porcelain pendent switches, porcelain surface switches, together with sub-bases, and porcelain push-button lamp sockets. The accompanying illustrations show the component parts of the mechan-



COMPONENT PARTS OF SWITCH.—A MOVING CONTACT-PIECE, A COILED STEEL SPRING AND A PUSH BAR.

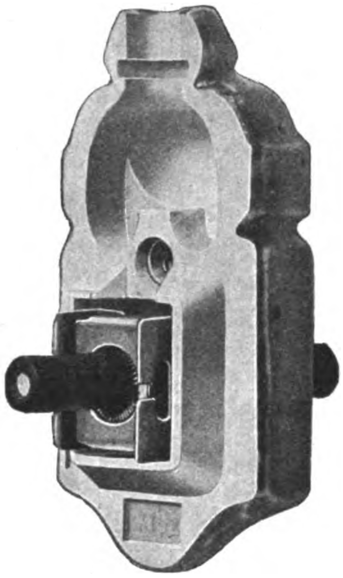
ism of these switches and also show some of the present applications. The illustrations, however, indicate only in a



PORCELAIN SURFACE SWITCH FOR CONCEALED WORK.

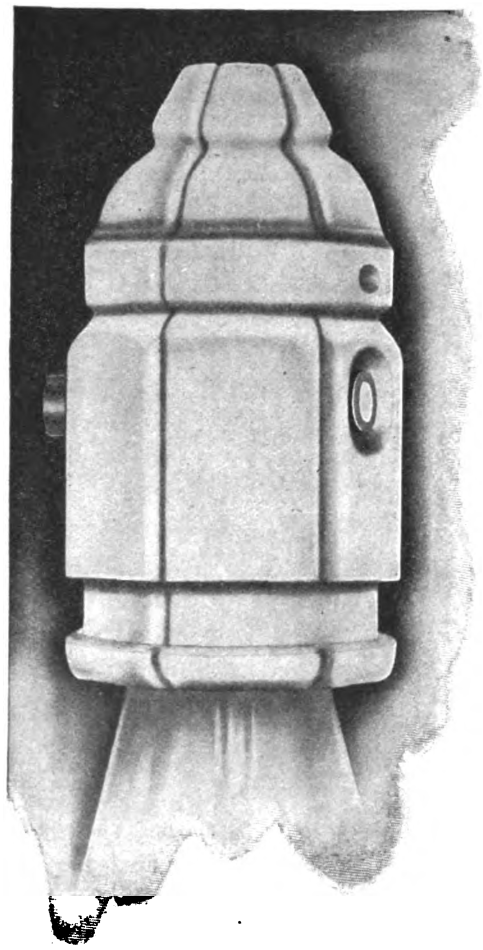
fashion the high degree of ingenuity which this device represents. The switch consists essentially of three parts, a push bar extending clear through the switch, a coiled steel spring and a moving contact-piece. These three elements may be assembled in any form of containing receptacle to perform any switch function which may be required.

The principle embodied in the switch mechanism is that of a coiled spring contracting on a tapering surface, the action being similar to that of a rubber ring slipped over the knob of an umbrella or a



SECTIONAL VIEW OF SMALL PORCELAIN PENDENT.

coiled-wire sleeve supporter which, when passed over the elbow, will travel a short distance up or down the arm of itself.

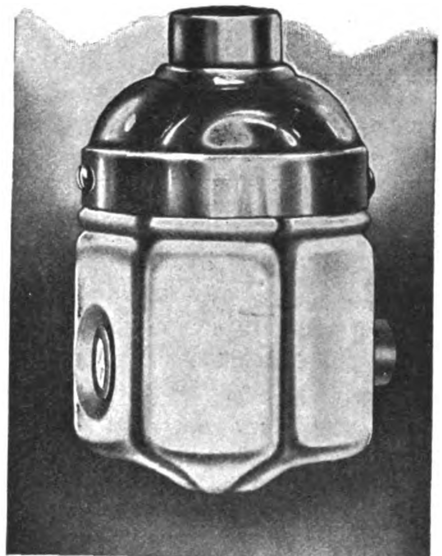


PORCELAIN PENDENT PUSH BUTTON LAMP SOCKET.

The action is snappy and positive in either direction. The mechanism gives a quick "make" as well as a quick "break," the movement of the contact-piece is the same whether the push-bar is moved fast or slow. The contact-piece can not be moved part way and let slip back again drawing an arc.

This new line of Cutler-Hammer push-button specialties is made of porcelain, which is non-corrosive and non-conductive. They will not tarnish and the user can not receive a shock, because all of the metal parts are encased in porcelain. Any slight arcing which might possibly occur is confined to a porcelain chamber away from the circuit wires and terminals. Liberal space is provided for knotting the flexible cord and the removal of a single screw gives access to the interior of the switch, making the wiring of these devices an easy matter. A removable fibre bushing is furnished with each of the pendent switches and the lamp socket, reducing the size of the outlet to the diameter of standard cord. When reinforced cord is used this bushing is removed.

The fire glaze on the porcelain is practically indestructible and the choice of



BRASS CAP PORCELAIN PENDENT SWITCH.

colors is such that a shade can be selected that will harmonize with the surrounding trim. The standard glazes are plain white, ivory tint, wood brown and neutral gray. Special glazes can be furnished to order.

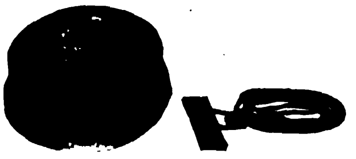
These devices have been approved by the Underwriters' Laboratories at Chicago.

A New Automobile Instrument.

The General Electric Company has lately placed on the market a new automobile instrument for use on electric vehicles. This instrument, known as the type DK, consists of a combination ammeter and voltmeter enclosed in a dust and moisture-proof aluminum case and is especially designed to withstand without injury the constant vibration and exposure incident to this class of service.

Both elements are constructed on the D'Arsonval principle. In the ammeter element a coil of wire carrying the current to be measured, or a shunted portion of it, is wound on a light aluminum frame, so pivoted in jeweled bearings as to move freely in a small annular space between a soft iron core and the pole-pieces of a permanent magnet. This element is identical with that of the type D switchboard instrument, with the exception of the permanent magnet, which is made somewhat larger in order that the voltmeter may be placed within the space enclosed by it.

The voltmeter has smaller parts throughout and differs slightly in construction. It has a circular form of armature frame instead of rectangular, and the core is a spherical piece of soft iron. Its general action is the same as that of the ammeter.



Combination Volt-Ammeter for Automobile Service.

It is a well-known fact that when magnets are subjected to constant vibration their efficiency is impaired and this must be taken into account in the design of automobile instruments. The magnets used in DK automobile instruments are made from the best quality of magnet steel obtainable, the special processes of ageing and hardening further insuring their permanency.

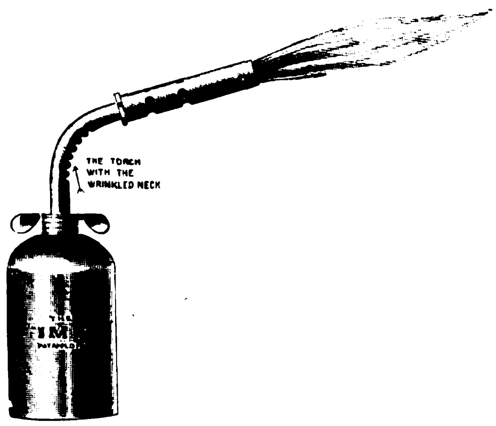
Another important advantage of DK instruments is the fact that they are strictly dead-beat, the pointer quickly coming to rest after each change in current or voltage. The scale divisions are very uniform and legible; this, together with the fact that the two scales are placed one above the other in close proximity, permits accurate simultaneous reading of volts and amperes. When desired, a suitable bracket carrying a miniature lamp with shade will be furnished for illuminating the dials.

The standard voltmeter scales are 120 and eighty volts. Either of two ammeter scales is standard, *viz.*, 150-0-150 or 70-0-150, the scales showing both charging and discharging current. Any other capacities of voltmeter or ammeter can be furnished when desired. It often becomes necessary to measure the voltage across individual cells and for this purpose a second voltmeter scale reading from 0 to 3 volts can be furnished on request.

The severe vibrations to which automobile instruments on commercial vehicles are subjected prevent the indications being read. To overcome this difficulty the General Electric Company has designed an "anti-vibration support," upon which the type DK instrument may be mounted. This is a new idea in automobile instrument construction and makes possible the use of indicating instruments on commercial vehicles. The black japan finish and the polished aluminum trimmings contribute to the neat appearance of the DK instrument.

A Powerful Gasolene Blow Torch.

The "Imp" torch, manufactured by the Frank Mossberg Company, of Attleboro, Mass., is a patented device which it is claimed will do as much work as most of the larger torches on the market, with the advantages of compactness, simplicity and cheapness. It is entirely automatic in operation, has no pump nor valve, needs no tools, starts with a match, and gives a perfectly clean, powerful Bunsen flame for over two hours on four ounces of gasolene.



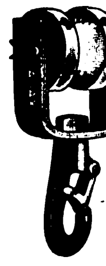
The "Imp" Gasolene Blow Torch.

The corrugated neck increases the heating surface to such an extent that the flame of a match easily generates gas enough for starting, after which the carefully designed mixing tube renders further attention unnecessary.

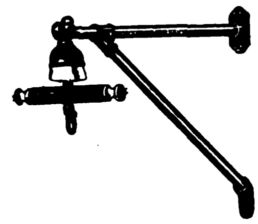
The "Imp" will be found valuable by electricians, automobilists, the handy man, and, in fact, any one who wants intense, clean heat, cheaply and quickly.

New Ajax Specialties.

The Ajax Line Material Company, Chicago, Ill., has added to its line of devices for contractors' use the three illustrated herewith. One is an insulated hook, designed as a low-priced insulator

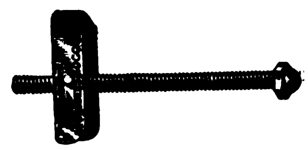


Ajax Insulated Hook.



Ajax "Mitre" Bracket.

for use with flaming and other arc lamps. Another is a modification of the regular Ajax toggle bolt having a detachable and ornamental head. This type was designed for plumbers' use, but is proving popular also for certain classes of electrical work. The third is a short arc lamp bracket for pole or wall use, with an insulating cross



Ajax Plumber's Toggle.

arm for guiding the wires and insulating the lamp. It is one of a series of easily erected fixtures designed to replace the crude riggings heretofore used.

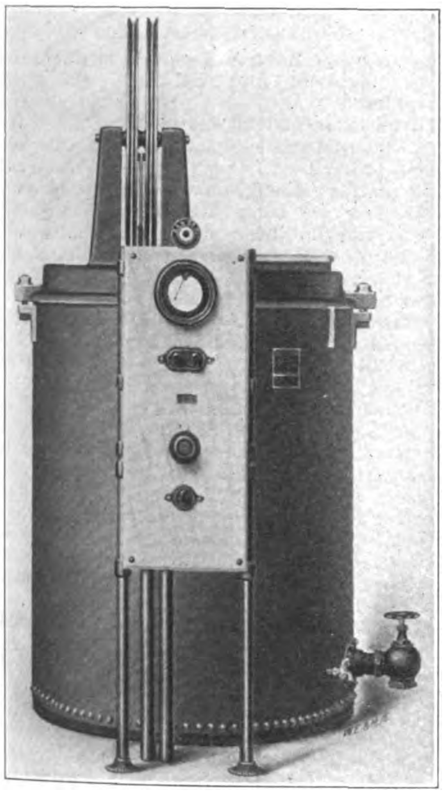
The "Success" Chemical Fire Extinguisher.

The H. W. Johns-Manville Company, 100 William street, New York city, has recently put on the market the "Success" portable fire extinguisher. This extinguisher is made of extra-heavy Lake Superior cold-rolled copper securely riveted and reinforced by heavy shoulders tested to withstand a pressure of 350 pounds per square inch. The method of attaching the dome to the body of the shell is said to make that joint the strongest part of the extinguisher. The large wheel at the top of the machine is a convenience in opening and closing it, at the same time serving as a base on which to rest the extinguisher when reversed. The framework or bottle holder containing the supply of sulphuric acid is cast brass and virtually indestructible. The bottle, of standard size and type, for holding the acid, is obtainable anywhere in case of accidental fracture from any cause. The hose, tested to 400 pounds per square inch, is only detachable with a wrench, being joined to the body by a swivel ground joint. This extinguisher is included in the list of approved chemical extinguishers issued by the National Board of Fire Underwriters.

Westinghouse Mercury Rectifier Arc-Lighting System.

In order to secure the advantages of direct-current series arc lamps and the alternating-current system of distribution and regulation, the Westinghouse Company has recently introduced a new system of arc lighting in which the most desirable points of both systems are combined. The alternating-current supply is changed to a direct-current by means of a Cooper Hewitt mercury rectifier, and this rectified current is then available for operating direct-current series arc lamps.

This system is applicable to all types of direct-current series carbon arc lamps, and also to the Westinghouse metallic flame



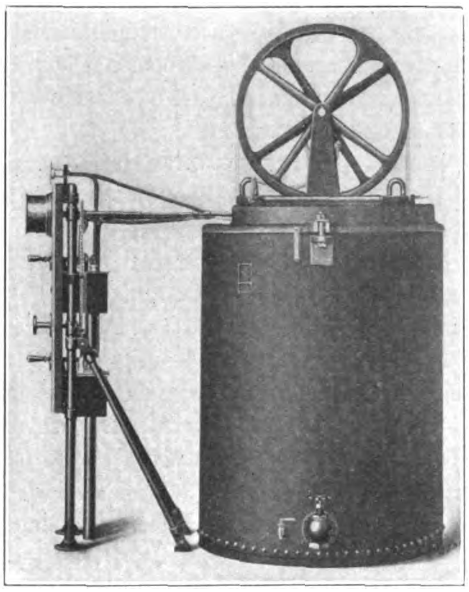
FRONT VIEW OF SEVENTY-FIVE-LIGHT MERCURY RECTIFIER, CONSTANT-CURRENT REGULATING TRANSFORMER OUTFIT.

arc lamp for which it is specially adapted. This lamp is a new development whose efficiency as a light producer is nearly double that of the carbon arc lamp. It is essentially a direct-current lamp, and as it requires a current of but four amperes, the existing arc generators as originally designed are not suitable for supplying current for it. These lamps, however, are extremely economical to operate because of their very high efficiency.

The combination of alternating-current regulating transformers and mercury rectifiers with any type of direct-current series lamps comprises a lighting system that is both simple and reliable, and that has proved highly successful in its practical applications. Its operation is devoid of any complications, and its notable economy makes its use extremely desirable.

The rectifier outfit consists of a constant-current regulating transformer, a mercury rectifier bulb, and a panel containing the necessary switches, instruments, etc. The regulating transformer and the rectifier bulb are mounted in the same tank, and by means of such outfits power may be drawn from an alternating-current circuit of either twenty-five or sixty cycles and delivered as direct current to the series arc lamp circuits. The rectifier bulb requires no manipulation except to start it, after which it operates without further attention.

The constant-current regulating transformer used with the rectifier set is of the repulsion coil type and is oil-cooled and oil-insulated. It is so arranged as to give a constant secondary current and to insu-



SIDE VIEW OF SEVENTY-FIVE-LIGHT MERCURY RECTIFIER, CONSTANT-CURRENT REGULATING TRANSFORMER OUTFIT.

late the arc lines from the primary circuit.

The rectifier bulb consists of a pear-shaped closed glass vessel about seven inches in diameter at its largest part. It is provided with four electrodes, the two upper ones being of graphite and the two lower ones of mercury. The bulb is exhausted to a high vacuum. Metal terminal thimbles are provided to which connections are readily made by spring clips or connectors.

The rectifier panels are made in four capacities, for twenty-five, thirty-five, fifty and seventy-five-lamp circuits, and are built of blue Vermont marble, supported upon a gas-pipe frame, which is braced to the floor. The three smaller-capacity panels are essentially similar and contain an ammeter, two oil switches, fuse blocks and fuses, a tilting handle and a pilot lamp in series with the arc circuit.

The ammeter is located at the top of the board and is connected in the direct-current lamp circuit. It is specially insulated so as to avoid all danger to attendants from grounding of its case.

The oil switch controlling the primary is double-pole. This may be double-throw when required. Suitable fuses are inserted in the primary leads to provide for short-circuit and overload protection. A double-pole oil switch also controls the secondary or direct-current series lamp circuit.

The seventy-five-light panels contain the same apparatus as the smaller-capacity panels, just described, except that the oil switch controlling the secondary is of a different type. In the seventy-five-lamp outfits the two bulbs are mounted so that both are tilted together. The secondary oil switch has two handles, one of which operates a double-pole switch in the lamp circuit and the other a single-pole switch which short-circuits one of the rectifier bulbs. For circuits of 6,600 volts and higher the fuse blocks are separately mounted.

The Dielectric Company of America.

The Dielectric Company of America, with factories and headquarters at Belleville, N. J., reports that its sales are showing considerable improvement and that the outlook for future business is very encouraging.

This company, although but recently organized, is meeting with marked success in its weatherproof-wire department, while its underground system is becoming more extensively used than ever. It is manufacturing the well-known DE brand of weatherproof wire which is exciting interest among the lighting plants and also among the signal engineers.

The Dielectric system of underground construction is designed to meet the demand for an underground system either for high or low potential, which is not as expensive as the present duct systems. Besides the advantage of first cost, the company claims that its system is also cheaper to maintain in that after the wires are once laid there is nothing to replace or repair. Besides these two very important lines, this company is also preparing to put on the market its HVH special wire, which is designed to be used in especially difficult places where a wire is required to not only carry a high voltage but to withstand the action of the elements and the action of acids, gas, etc.

New Receiver for New York City Railway.

By continuing Adrian H. Joline and Douglas Robinson as Federal receivers for the Metropolitan Street Railway Company and appointing William W. Ladd as receiver for the New York City Railway Company in their stead, Judge Lacombe of the United States Circuit Court on July 16 carried out his decision that the companies should have separate receivers. Mr. Ladd will take up his duties August 1. The court directs Joline and Robinson to file with the court, not subsequent to August 1, a statement of receipts and expenditures of the dual receivership to July 1. It was on a motion made by Bronson Winthrop, representing the Morton Trust Company, that the Metropolitan receivership was separated from the New York City Railway receivership. In that motion the Guaranty Trust Company joined. The separation is made for the purpose of expediting foreclosure proceedings. Mr. Ladd was appointed on motion of Benjamin S. Catchings, who represented the tort creditors' committee of the New York City Railway Company. Mr. Ladd's bond was fixed at $50,000.

Judge Lacombe said that when the same receivers were appointed for the Metropolitan and the New York City Railway the lease of the Metropolitan system to the New York City Railway still was in force and no suit to foreclose mortgage had been instituted. Since then the situation has changed, he said. A regular foreclosure suit against the Metropolitan for unpaid interest under refunding mortgage has been instituted and the court said it was fitting that the property covered by that mortgage should be taken over by receivers under that suit who would operate the Metropolitan system alone. Judge Lacombe said that the clause in the lease deferring re-entry for non-payment of rent until one year after default presented no difficulties. There was not merely a simple default, he asserts. Because of the inability of the receivers to pay from the income the mortgage interest due January 1, 1908, on the Third Avenue mortgages that line had been foreclosed upon, and an independent receiver appointed, who has taken it into possession, thus disrupting and destroying the original system covered by the lease.

It was ruled by the court that the present bonds of Joline and Robinson might be extended to cover their future operations. The court included in its opinion assurances that the receivers for the Metropolitan would adopt and affirm all contracts which related to the operation of the system which were adopted or entered into by receivers for the New York City Railway. Judge Lacombe said the court reserved the right to impose a lien upon the property itself for any obligations incurred by the court in its operation of the railways and also for the expense of the court proceedings.

Mr. Ladd, the new receiver for the New York City Railway, formerly was deputy city chamberlain, resigning that office to resume the practice of law. He was a member of the board which prepared the Military Code adopted by the Legislature in 1898. He served four years as assistant corporation counsel. He is now a practicing lawyer in No. 20 Nassau street.

International College Comity—A Unique Ceremony.

University and college degrees are occasionally, in exceptional cases, conferred *in absentia*. It has remained for Lehigh University, acting in conjunction with the University of Liverpool, England, to signalize a new and most interesting departure in the practice, replete with kindly expressions of international comity and friendship on the part of the University of Liverpool.

In June last Lehigh University awarded to Horace Field Parshall, of London, England, the honorary degree of Master of Science, this being the fourth honorary degree ever granted by Lehigh. Mr. Parshall is an American who has built up in England a practice as a leading electrical engineer. He is well known as an author; his joint work with H. M. Hobart on "Electric Railway Engineering" is an engineering classic. Mr. Parshall is a graduate of the course in electrical engineering of Lehigh University of the year 1887. For some ten years after his graduation his work was in this country, during which time he held in 1894, in the Massachusetts Institute of Technology, a lectureship on the designing of electrical machinery. Since 1897 he has been resident in London and has been engaged largely in the introduction of electric traction into Great Britain, and is now engaged as expert on the hearings before a parliamentary commission on the London and District Electricity Supply Bill. This engagement prevented Mr. Parshall coming over here in June to receive the degree at Lehigh's commencement exercises, and resulted in the arrangement by which the University of Liverpool graciously undertook the duty of conferring the degree on behalf of Lehigh University.

Vice-Chancellor Dale, of the University of Liverpool, in writing President Drinker the acceptance by the University of Liverpool of the duty of conferring the degree, gives the following kindly expressions of cousinly goodwill:

The council and senate of this university have agreed to act on the suggestions that you make, and to confer formally on Mr. Parshall the honorary degree that has been awarded to him by the university over which you preside. When the hood and diploma have reached us I will then arrange with Mr. Parshall for his formal admission to the degree.

So far as I am aware, no precedent or parallel for such an act can be found in the history of British universities. But it is our business to make precedents as well as to follow them, and we trust that in so doing our act will be regarded as an expression of fellowship and sympathy with kindred institutions carrying on similar work, established for similar services, and bound to us by many ties.

The letter of attorney from Lehigh to Liverpool was couched as follows:

Whereas, Horace Field Parshall, in the year eighteen hundred and eighty-seven, completed at Lehigh University the special course in electrical engineering then given by the university, and since that time has risen to high eminence in his profession, and has distinguished himself and has reflected honor on his Alma Mater by his scientific work and publications, and the university is desirous of recognizing his achievements in this regard, and of doing honor to one who has so honored himself; and,

Whereas, The said Lehigh University has decided to confer upon the said Horace Field Parshall the honorary degree of Master of Science; and,

Whereas, The said Horace Field Parshall is engaged in Great Britain in the pursuit of work of such importance as to make it impracticable for him to attend at the university at South Bethlehem, Pa., at the university's commencement exercises on June tenth, nineteen hundred and eight, to receive said degree, and the authorities of the University of Liverpool have graciously offered to act as the representatives of Lehigh University in the act of conferring said degree;

Now Know All Men by These Presents, That the Lehigh University, an educational corporation existing under the laws of the state of Pennsylvania, in the United States of America, hereby nominates and appoints the chancellor of the University of Liverpool or such person as he may designate to confer for and on behalf of the Lehigh University and by its authority, and as its attorney and representative, upon the said Horace Field Parshall, the degree of Master of Science, and in testimony thereof to deliver to the said Horace Field Parshall the diploma of the Lehigh University evidencing said degree.

Witness the seal of the said the Lehigh University this day ,
A. D., nineteen hundred and eight.

Henry S. Drinker,
President of Lehigh University.

W. A. Lathrop,
President of the Board of Trustees.

Seal of Lehigh University.

Attest:
E. P. Wilbur,
Secretary of the Board of Trustees.

At the ceremony of July 2 Mr. Parshall was presented by the dean of the faculty of science of Liverpool University for admission to the degree and the vice-chancellor conferred the degree and delivered to him the diploma of the Lehigh University conferring the degree.

Current Electrical News

DOMESTIC AND EXPORT.

MISSOURI ELECTRIC RAILWAY DEAL—A despatch from St. Louis states that the United Railways Company and the North American Company have incorporated a subsidiary company known as the Missouri Electric Railway Company, into which will be consolidated all the electric lines in St. Louis County. The capital is $1,000,000. The incorporators are acting for the United Railways management and the North American Company interests, which control that company.

GREAT WESTERN POWER COMPANY TO BUILD PLANT AT EAST OAKLAND—The Great Western Power Company has started the erection of what will be one of the greatest power plants on the coast. The site for the new power-house is at the end of Fourth avenue in East Oakland. The new plant will cover several thousand square feet of ground on the west side of Fourth avenue, and according to the plans of the company, will be one of the most completely equipped in the state.

A MILLION DOLLARS FOR IMPROVEMENTS—The Coney Island & Brooklyn Railroad is installing a number of improvements that Superintendent D. W. Sullivan says will cost considerably more than $1,000,000. One of the principal of these, the burying of overhead feed wires, is now practically completed. A conduit has been laid along the entire system from Coney Island, and the cables installed under the immediate supervision of Mr. Murphy, the electrician of the road. These are now in operation, and it is through them the power is now being supplied to operate the cars on the Smith street, DeKalb and Franklin avenue lines. The overhead wires have already been removed between the depot at Smith and Ninth streets and the Park Circle, and the remainder will come down in short order. The most striking improvement, however, is the new building that is being erected for the power plant at Smith and Ninth streets. There will be generated the entire power to run the lines of the road.

SYNDICATE SEEKING TO CONTROL MONTREAL LIGHT, HEAT AND POWER COMPANY—An American syndicate with $40,000,000 capital, headed by Leslie M. Shaw, formerly Secretary of the Treasury, is said to be negotiating for control of the Montreal Power Company, with the intention of subsequently gaining control of a number of other Canadian public service corporations, including the Montreal Street Railway and some Toronto franchises. The syndicate is known as the Canadian Public Service Corporation. It proposes to guarantee six per cent for the first year, seven per cent for the second and eight per cent thereafter on the stock of the Montreal Power Company in return for an option to purchase the stock during the first year at 110, during the second year at 112½, and so on at an annually increasing price of 2½ points up to 135. As a guarantee of the dividend the corporation proposes to deposit $8,000,000 with a Montreal trust company, in the event of its acquiring controlling interest.

ONONDAGA INDEPENDENT TELEPHONE COMPANY—At the first meeting of the directors of the Onondaga Independent Telephone Company, held in Rochester last week, Alexander H. Cowie, of Syracuse, was elected president; John B. Pierce, manager of the old Independent Telephone Company of Syracuse, was elected general manager and assistant treasurer of the new company. George R. Fuller, of Rochester, N. Y., was chosen vice-president and W. Roy McCanne secretary and treasurer. The other directors are Hendrick S. Holden, of Syracuse, and Joseph W. Taylor and Edward W. Peck, of Rochester. The Onondaga Independent Telephone Company took possession of the properties of the Independent Telephone Company of Syracuse on July 13. All the property of the old company, including the exchange in that city and lines to various towns and cities in central New York, was bid in on behalf of the reorganization committee at the mortgage foreclosure sale July 3. Under the plans of reorganization the title is now turned over to the Onondaga company.

ELECTRIC RAILWAYS.

FITCHBURG, MASS.—The Fitchburg & Leominster Street Railway Company has petitioned the Railroad Commission for approval of an issue of 2,500 additional shares of stock to be offered stockholders at $100 per share.

HAMMONDSPORT, N. Y.—The Appellate Division of the Supreme Court has annulled the decision of the former State Railroad Commission to grant to the Bath, Branchport & Hornell Electric Railroad a certificate of public convenience and necessity. The annulment is made on the ground that contrary to law one-tenth of the minimum amount of capital stock of the company had not been subscribed and paid.

EVANSVILLE, IND.—The annual election of the Evansville Railway Company, operating the Evansville and Mt. Vernon and the Evansville and Rockport traction lines, held in this city on July 6, resulted as follows: President, W. L. Sonntag, Evansville; vice-president, W. I. Rudd, Rockport; secretary, Fred W. Reitz; treasurer, Marcus S. Sonntag; directors, W. H. McCurdy, chairman; John M. Funke, Fred W. Reitz, C. H. Batten, Philip Speck, M. S. Sonntag, Wm. M. Ford, Chris Kanzler, W. L. Sonntag, A. F. Karges and W. I. Rudd.

OREGON, MO.—The contract for building the Oregon Interurban Railway has been awarded to W. M. Wogan, of Leavenworth, Kan., for $40,000, this amount to make the road ready for the rolling stock—building bridges, culverts and fills, and laying the ties and steel, including sidetracks and putting in all other necessary fixtures aside from the engines and cars. The road is to be completed and ready for the rolling stock by October 1 next. The Oregon Interurban Railway is to be built from the Burlington yards at Forest City to a point four and a half miles distant, at the northern edge of the city of Oregon. It will be of standard gauge, and capacity for all sizes of rolling stock used upon the main line of the Kansas City, St. Joseph & Council Bluffs Railway. Thirty-seven bids for the contract were filed with the company.

HARRISBURG, PA.—Governor Stuart has approved the merger of eight trolley lines in western Pennsylvania under the name of the Suburban Railway Company, with a capital of $150,000 and offices at Rochester. The companies consolidated are the original Suburban Company, the Freedom & Baden Electric Street Railway Company, Sewickley & Leetsdale Electric Street Railway Company, Beaver & Bridgewater Electric Street Railway Company, Beaver Falls Electric Street Railway Company, Rochester, Beaver & Vanport Electric Street Railway Company, New Brighton, Beaver Falls & Marado Electric Street Railway Company and Economy and Harmony Electric Street Railway Company. The new company will have these officers: W. A. Park, Rochester, president; Samuel Morgan, Freedom; J. H. Park, P. A. Smith and Charles Connel, New Brighton.

CLEVELAND, OHIO—The Municipal Traction Company, which is operating all the street car lines in Cleveland under the plan carried out by Mayor Johnson, reports a deficit of $34,916 for the month of May. Mayor Johnson says this deficit is largely due to the strike of the street railroad men. Taking that into consideration, he says the statement is satisfactory. The company must pay operating expenses and six per cent dividend on the stock or forfeit its right to operate the lines. The lines have been operated at three cent fare a little over two months, but one cent is charged for each transfer. Judge Phillips, in Common Pleas Court, has granted a mandatory order compelling the Municipal Traction Company to give good service and the same rate of fare to the town of East Cleveland, a suburb, as is enjoyed by the city of Cleveland. The court held this was compulsory under the original franchise granted to the street-car company by the suburban town. The Municipal Company, when it recently took over the street-car system, announced that three-cent fares would prevail only within the city limits and that the fare to and from the suburban towns would be five cents.

TELEPHONE AND TELEGRAPH.

DOVER, N. H.—The New England Telephone and Telegraph Company will construct a telephone line from Dover to Eliot.

CONESTOGA, PA.—The Conestoga Telephone Company is making a number of improvements to its exchange at Birdsboro, including the rebuilding of the switchboard.

OMAHA, NEB.—The Independent Telephone Company is preparing to start work on its building in South Omaha. This will have a capacity of 5,000 telephones and is expected to be in operation by November 1.

HARTFORD, WIS.—The special election held recently for the purpose of voting on the proposition to install a municipal electric light plant resulted favorably to the plan. A plant to cost $27,000 will be installed, to do commercial as well as street lighting.

MARSHALLTOWN, IOWA—The Marshall Telephone Company, which was recently amalgamated with the Bell system, locally, has purchased a centrally located business building, and will spend $10,000 in improving and building an addition forty by fifty-one feet.

FLORENCE, UTAH—John B. Morris, of Erie, Pa., and Robert E. Archibald, of Cleveland and San Francisco, representing a syndicate of Brooklyn and Philadelphia capitalists, have announced that they will build an electrical power plant and a custom mill in this district.

WHEELING, W. VA.—Dr. John L. Dickey and Samuel W. Harper have been elected directors of the National Telephone Company. The board organized with the Hon. John A. Howard as president; S. W. Harper, treasurer and vice-president, and William C. Handlan as secretary and manager.

PROVIDENCE, R. I.—It is announced that it is the intention of the Narragansett Electric Lighting Company to install a 4,000-horse-power steam turbine within the next four months. The present capacity of the station is 15,000 horse-power, which is not now sufficient for the winter load.

CHICAGO, ILL.—A new telephone exchange designed to provide ultimately for 10,000 subscribers has been established by the Chicago Telephone Company in the downtown business district. The new office is called "Franklin" and has been opened to relieve congestion and take care of future growth in the "Main" district.

SYRACUSE, N. Y.—The plant of the Syracuse Independent Telephone Company has been sold in mortgage foreclosure proceedings. Roy McCanne, of Rochester, bid in the property in behalf of the reorganization committee of the United States Independent Telephone Company for $25,000, but this is subject to a mortgage for $1,250,000.

LINCOLN, NEB.—A fee of $5,003 was paid by the Independent Long-Distance Telephone Company of Omaha for filing articles of incorporation with the secretary of state. The company is organized with an authorized capital stock of $10,000,000. The incorporators are: T. C. Williams, of Farlin, Iowa; C. C. Ludy, Cooper, Iowa, and D. W. Study, Jefferson, Iowa.

NASHVILLE, TENN.—The Mine City Telephone Company, of Polk County, has been granted a charter. The company proposes to own, operate and construct a telephone line from Ducktown to Copper Hill and other places in Polk County. The capital stock is $500 and the incorporators are: J. M. Kilpatrick, Carl Center, C. M. Campbell, W. S. Love and W. I. Morris.

COLVILLE, WASH.—H. R. Williams, of Spokane, has purchased the entire stock of the Northwestern Light and Power Company, which operates the plant at Meyers Falls that supplies the towns of Kettle Falls, Meyers Falls, The Mission and Colville with light and power. The system was established five years ago, the company being promoted and controlled by T. A. Winter.

OLYPHANT, PA.—The light committee appointed by the Olyphant council to investigate the condition of the municipal lighting plant and report on the advisability of accepting the offer of the Scranton Electric Company to purchase the plant have decided it would be well to buy power from the local company, but voted to maintain the electric plant under municipal management.

KANSAS CITY, MO.—The telephone line of the American Telephone and Telegraph Company between Kansas City and Denver has been completed and put into operation. Heretofore the entire United States has been divided from a telephonic standpoint by a region in a line north and south with the western half of Kansas. The service inaugurated is the first telephone line to bridge the gap.

RICHMOND, IND.—A deal has been consummated between the Richmond Home Telephone Company and the Central Union Telephone Company, as a result of which the independents will gain entrance to Minneapolis and other large cities. This will effectually open up the Northwest to the independents, Richmond being one of the most important points in the independent system of the Mississippi Valley.

BILLINGS, MONT.—Following the purchase of the electric light plants of the Billings Water Power Company and Yegen Brothers by the Eastern Montana Power Company, the work of connecting the two systems has begun. The plants are located about one-half mile apart on the Yellowstone River. According to arrangements which the new company has in view a transmission line will extend throughout eastern Montana.

PEORIA, ILL.—The Farmers' Mutual Telephone Company, with a capital of $20,000, has organized by the election of the following officers: President, John Sommers, of Elm Grove; vice-president, John Strickfaden, Groveland; secretary-treasurer and manager, Arthur Becker, Tremont. Trustees, Samuel Kinsinger, Groveland; Theodore Schwarzentraub, Morton; A. L. Robison, Elm Grove; Henry Bollinger, Tremont; Robert Kennedy, Dillon; Joseph Augsburger, Hopedale.

MILWAUKEE, WIS.—It is announced that the American Telegraph and Telephone Company, which has been engaged in laying an underground telephone system between Milwaukee and Chicago, has completed the line between this city and Racine, and expects to have the line completed to Chicago in the fall. The underground system will be connected up with the telephone exchanges in the cities and villages between Chicago and Milwaukee. The Wisconsin Telephone Company is extending its lines to Rhinelander, Minocqua and other points in northern Wisconsin.

REXBURG, IDA.—At a meeting of the city council an ordinance was passed granting a franchise for the use of the streets and alleys of Rexburg to the Idaho Power and Transportation Company, Limited, for transmission and distribution of electric current. The headquarters of this company is at Idaho Falls. The rates are $7 per month for arc lights, ten cents per kilowatt-hour and a flat rate of seventy-five cents for first lamp, fifty cents for the second lamp and forty cents for the third lamp of sixteen candle-power. The service will be twenty-four hours per day.

NEW PUBLICATIONS.

STRENGTH OF CONCRETE BEAMS—The United States Geological Survey has issued a bulletin, No. 344, on the strength of concrete beams. It gives the results of testing of 108 beams, conducted at the Structural Materials Testing Laboratory. This report, which has been prepared by Richard L. Humphrey, describes the structure of the beams and method employed in testing them.

COLUMBIA UNIVERSITY BULLETIN OF INFORMATION—Columbia University, New York city, has published a bulletin of information concerning the Schools of Mines, Engineering and Chemistry. This takes up the departments of mining, metallurgy, civil engineering, electrical engineering, mechanical engineering, chemical engineering and chemistry for the 1908-1909 course.

THE INLAND EMPIRE SYSTEM—The publicity department of the Inland Empire System has prepared a number of very handsome illustrated bulletins devoted to the pleasure resorts and routes of the Spokane & Inland Empire Railroad Company, the Idaho & Washington Northern Railroad, and the Red Collar Steamship Line. There is a description of the Bozanta Tavern, at Hayden Lake, Ida.; the system of the Idaho & Washington Northern Railroad; excursions to the shadowy St. Joe River, Idaho, the Pend Oreille River route, through the pines to Spokane Lake resorts, and profitable farming in the Spokane country. Charles E. Flagg is the manager of publicity.

PERSONAL MENTION.

MR. E. R. KNOWLES, the well-known consulting engineer of New York city, is an active member of the Building Code Revision Commission of New York city, appointed by the board of aldermen.

MR. A. W. CLAPP, who had under preparation a volume entitled "Hydroelectric Plants of United States, Canada and Mexico," and who had gathered together a considerable amount of valuable data, has some mail for him at the office of the ELECTRICAL REVIEW. If he will send us his address this mail will be forwarded.

MR. F. N. DRESING, chief of the Chinese Imperial Telegraphs and special delegate representing the Chinese Minister of Communications to the Lisbon International Telegraph Conference, was a visitor to New York and Chicago last week, where he spent some time with various electrical interests. He will return to China, by way of San Francisco, the latter part of July.

MR. DAVID S. MURRAY, general manager of the Rocky Mountain Bell Telephone Company, was tendered a banquet at the Elks Club, Salt Lake City, and presented with a handsome gold watch and fob by his associates upon the occasion of his leaving the company. Mr. Murray severed his connection with the Rocky Mountain Bell Telephone Company a few weeks ago to accept an executive position with the Pacific States Company of San Francisco, and completed his service there a week ago. His career has extended from 1884, when he began as a collector and worked his way steadily upward until a few years ago, when he became general manager. During his administration the company has grown greatly, and there is a great deal of regret among the employés at his departure. From small beginnings the company has now extended its influence over four states and spread lines into practically every town and city of that territory.

MR. WILLIAM H. BROWNE has been appointed general manager of the Rockingham Power Company, which has in progress of construction at Rockingham, N. C., a 66,000-volt, three-phase, hydroelectric development of considerable magnitude. Mr. Browne is now on the ground actively superintending construction. Mr. Browne's connection with the electrical industry dates back to 1888 in the building of the electric railroad at Richmond, Va. Following this, he was associated with the Westinghouse interests in New York city and later was general manager of the United Electric Light and Power Company, of New York city. From 1894 to 1895 he was receiver of the Flushing & College Point Railway, Flushing, Long Island. From 1895 to 1902 he was general manager of the Royal Electric Company, Montreal, Canada. From 1902 to 1906 he was treasurer and general manager of the Stanley Instrument Company, Great Barrington, Mass.

NEW MANUFACTURING COMPANIES.

HOBOKEN, N. J.—The Gross Electric Company has been incorporated with a capital of $25,000 to act as mechanical engineer, electrician, etc. The incorporators are: H. Wilkens, C. B. Wilkens and S. Gross, of Hoboken.

COLUMBUS, OHIO—The Canton Telephone Seal and Lock Company, of Canton, has been incorporated with a capital of $10,000 by E. C. Hill, Edward Rowmel, J. L. McDonald, T. E. Phillippi, E. H. Forester and W. C. Wingwire.

NEW YORK, N. Y.—Edwards & Company, Incorporated, Bronx, has been incorporated to manufacture electric apparatus, machinery, etc., with a capital of $75,000. The incorporators are: R. Edwards, Jr., Rochelle Heights; E. Lunger, Bronx; R. G. Mead, New York city.

TRENTON, N. J.—The Hicks Motor and Manufacturing Company, of Garwood, has been incorporated to manufacture dynamos, motors, etc., for the generation or use of electricity or other energy. The capital is $25,000. Incorporators: A. B. Craft, Cranford; H. E. Hicks, Plainfield; W. B. Elliott, Westfield.

ELECTRICAL SECURITIES.

All during the week stocks were buoyant on reports of bettering conditions in all phases of industry and prospects of large crop returns. Leading securities made advances ranging from a fraction to four and five points over last week. The rumors of advances in freight rates caused a little apprehension, and if these are persistent a reaction in prices of securities is not to be unexpected.

Dividends have been declared upon the following electrical securities: American District Telegraph; regular quarterly dividend of 1 per cent, payable July 22; books close July 14 and open July 22. Michigan State Telephone Company; regular quarterly dividend of 1½ per cent on the preferred stock, payable November 2, 1908; books close October 20 and reopen November 4; also regular quarterly dividend of 1 per cent on the common stock, payable September 1; books close August 20 and reopen September 2. The New Bedford Gas and Electric Light Company; regular dividend of 2½ per cent, and an extra dividend of 20 per cent. Amalgamated Copper Company; regular quarterly dividend of 50 cents per share, payable August 31 to stock of record July 23. Railway and Light Securities Company; regular semiannual dividend of $3 per share on the preferred stock, payable August 1 to stock of record of July 20. New York & Queens Electric Light and Power Company; a regular semiannual dividend of 2½ per cent on the preferred stock, payable August 10 to stock of record July 31.

ELECTRICAL SECURITIES FOR THE WEEK ENDED JULY 18.

New York:	*Closing.*
Allis-Chalmers common	10⅞
Allis-Chalmers preferred	34½
Brooklyn Rapid Transit	60⅝
Consolidated Gas	126
General Electric	143¼
Interborough-Metropolitan common	11½
Interborough-Metropolitan preferred	31¾
Kings County Electric	109½
Mackay Companies (Postal Telegraph and Cables) common	65
Mackay Companies (Postal Telegraph and Cables) preferred	66¾
Manhattan Elevated	137½
Metropolitan Street Railway	23
New York & New Jersey Telephone	107½
Western Union	55⅝
Westinghouse Manufacturing Company	60¼

The Allis-Chalmers Company continues to report an improvement in its business. Orders received in the month of June show an increase of twenty per cent over the preceding month. New business in the month of May showed an improvement of eighty per cent over April. A representative of the company says that collections are better than they have been at any time in several years.

Shares of the Westinghouse Electric and Manufacturing Company made substantial gains on reports that the success of the reorganization plan is now assured and that it will be ratified by the readjustment committee when it meets September 1.

Boston:	*Closing.*
American Telephone and Telegraph	117⅝
Edison Electric Illuminating	216
Massachusetts Electric	46
New England Telephone	113
Western Telephone and Telegraph preferred	63½

American Telephone and Telegraph for the past three years has found its banking and financing relations with its subsidiary telephone associates relatively more profitable than the purely investment and banking relationship. On the whole, and as compared with the showings of American industrial corporations, the telephone companies are doing a business of increasing size and profit, and with rather slight fluctuations in pace. While the three years culminating with 1907 was a period of enormous demands for capital for construction and development, the results in earnings are of approximately equal magnitude.

Directors of the Western Telephone and Telegraph Company have declared the regular semiannual dividend of two and one-half per cent on the preferred stock, payable August 1 to stock of record July 18.

Philadelphia:	*Closing.*
Electric Company of America	10⅛
Electric Storage Battery common	30
Electric Storage Battery preferred	32½
Philadelphia Electric	9½
Philadelphia Rapid Transit	13⅞
United Gas Improvement	87

Chicago:	*Closing.*

National Carbon preferred	110

ELECTRIC LIGHTING.

CHARLOTTE, N. C.—The Southern Power Company has completed its transmission line to Shelby.

MUNNSVILLE, N. J.—Munnsville has raised $1,200 toward capitalizing an electric light proposition, selling the shares at $10 each.

SAN JOSE, CAL.—The Tuolumne Water Power Company has been granted a franchise by the board of supervisors of Santa Clara County.

SACRAMENTO, CAL.—The Snow Mountain Power Company, of Willows, Glenn County, will commence work on its plant some time in August.

SHREWSBURY, MASS.—The selectmen have voted to borrow $16,000 to establish an electric lighting plant, which the town authorized at a special meeting in May.

OXFORD, MASS.—The contract for the construction of the heat and light plant of the University of Mississippi has been awarded Barber & Company, of Birmingham, Ala.

BROWNWOOD, TEX.—The city council has closed a deal for twenty street lights to be installed in Brownwood within the next ninety days, the contract price being $6.75 per light per month.

TRAVERSE CITY, MICH.—F. E. Hatch, of Pellston, has purchased the Chandler dam at Leland and proposes to install a power-house to supply electricity for Leland, Provement, Sutton's Bay and Northport.

BUTLER, MO.—At the annual meeting of the stockholders of the Butler Water, Light and Power Company the following directors were elected for the ensuing year: Dr. J. M. Christy, J. P. Edwards, J. S. Francisco and J. A. Trimble.

WEST ALLIS, WIS.—Articles of incorporation of the West Allis Light and Power Company have been filed with the register of deeds of Milwaukee County by F. C. Weed, H. G. Meigs and J. B. Meigs. The new company has applied to the city council for a franchise.

ALBANY, N. Y.—The Public Service Commission for the Second District has granted the application of the Canton Electric Light and Power Company for authority to mortgage its property and franchise for $16,000 and to issue $16,000 bonds to be secured by the mortgage.

MILFORD, MASS.—At a meeting of the selectmen a contract with the Milford Light and Power Company was ratified for one year for street lighting. The contract includes fifty-eight arc lamps of 1,200 commercial candle-power at the rate of four cents an hour for each lamp.

ALBANY, N. Y.—An agreement of consolidation of the Watertown Light and Power Company and the Watertown Gas Light Company, forming the Watertown Light and Power Company, has been filed with the secretary of state. The capital of the consolidated concern is $1,500,000.

VICTOR, MONT.—An electric light company has been formed and work has begun on a plant to supply light and power to Victor and Stevensville. The plant will be located on the Bitter Root River at Victor and an excellent site has been secured. The company promises service by early fall.

ALBANY, N. Y.—The Public Service Commission of the Second District has granted the application of the Berlin Electric Light, Heat and Power Company for permission to begin construction and examine franchises in the town of Berlin, Rensselaer County, and also to issue common stock to the amount of $17,500, the necessary cost of constructing its plant.

MUSCATINE, IOWA—The city council has passed a bill authorizing the board of public improvements to let a lighting contract, the cost of which will be about $800,000 per annum, for the lighting of the public streets at the expiration of the present contract in 1910. The council also passed a bill providing a franchise for the company that bids the lowest on the contract.

SPRINGFIELD, MASS.—For the purpose of doubling its capacity, the Home Light, Heat and Power Company intends to erect another building east of its present plant in East Washington street. A permit for a $2,000 brick structure has been issued to the company. The dimensions of the building will be fifty-three by sixty-six feet, one story high. Modern machinery will be installed.

STOCKBRIDGE, MASS.—The contract between the town and the Stockbridge Lighting Company for street lights, authorized by vote of the town at the annual meeting, has been signed. It is a twenty-year agreement providing for the use of not less than eighty lamps. The town is to pay $27 per year for each light served by the underground conduit system and $15 per year for each served from overhead wires.

COLORADO SPRINGS, COL.—Pursuant to action taken at a special stockholders' meeting in this city June 22, Vice-President R. W. Chisholm and Secretary Ira A. Miller, of the Colorado Springs Electric Company, have filed a certificate of amended articles of incorporation of the company in the county clerk's office, increasing the capitalization from $1,000,000 to $1,500,000. The capitalization will consist of 10,000 shares of common and 5,000 shares of preferred stock, all of a par value of $100 each.

LEXINGTON, KY.—Agitation against the rates for electric lighting and power has resulted in the passage by general council of an ordinance for sale of a franchise for a new company. The ordinance provides that the maximum rate for lighting shall be fifteen cents per 1,000 watts; that the life of the franchise shall be twenty years; that the plant shall not be sold to a competitive company, and that the Lexington Railway Company, which now has a monopoly here, shall not be a bidder. Colonel John R. Allen stated that a company, largely of local men and ample capital, is to be formed and will bid for the franchise. It is required that work on the plant begin not later than January, 1909.

NEW INCORPORATIONS.

CLEVELAND, OHIO—Mahoning Telephone Company, Youngstown. $10,000.

DES MOINES, IOWA—Dubuque & Delaware County Telephone Company, Dyersville. $100,000.

CINCINNATI, OHIO—Belmont Telephone Company, Bridgeport. Increase of capital from $150,000 to $250,000.

NASHVILLE, TENN.—Doe River Lighting and Power Company, Carter County. Capital stock increased from $10,000 to $15,000.

PARKERSBURG, ORE.—Parkersburg Telephone Company, Parkersburg. $2,000. Incorporators: Albert Snead, Wesley J. Haga and E. M. Randleman.

CHEYENNE, WYO.—The Cheyenne Street Railway Company. $75,000. Incorporators and directors: T. A. Cosgriff, H. M. Bennett and G. E. Abbott.

ST. PAUL, MINN.—White Earth Telephone Company, Mahnomen. $10,000. Incorporators: Charles H. Sanders, Mabel M. Sanders, Kathryne Sanders and L. G. Sanders.

ST. PAUL, MINN.—Russell Farmers' Mutual Telephone Company, Russell, Lyon County. $10,000. Incorporators: A. J. Burckhardt, president; W. C. Henrich, general manager.

ST. PAUL, MINN.—Anoka County Mutual Telephone Company, of Constance. $4,500. Incorporators: William Nelson, of Constance, president; Fred Russell, of Cedar, secretary; P. J. Johnson, of Constance, treasurer; John Simonson, Charles Haglund and Gust Soderburg, directors.

ST. LOUIS, MO.—Missouri Electric Railroad Company. $1,000,000. Incorporators: Robert McCulloch, 9,900 shares; Bruce Cameron, E. P. Walsh and H. P. Taylor, ten each; James Adkins, seventy. To construct, own and operate street railroads in St. Louis, Mo., and St. Louis County and St. Charles County, Missouri.

NASHVILLE, TENN.—Gallatin Pike Railway Company, Davidson County. $25,000. Incorporators: E. B. Rucker, C. H. Gillock, M. H. Sharpe, P. A. Shelton and J. H. Zarecor. Organized for the purpose of building and operating a railroad along the line of the Gallatin Pike from the present extension of the Nashville Railway and Light Company's road to a point on said pike where it is intersected by Maplewood Lane, a distance of about two miles.

INDUSTRIAL ITEMS.

THE ROBBINS & MYERS COMPANY, Springfield, Ohio, has issued bulletin 67, a handsome piece of literature devoted to "The Standard" motors.

THE CROCKER-WHEELER COMPANY, Ampere, N. J., in bulletin 105, describes and illustrates polyphase induction motors, constant speed, large sizes, sixty cycles, fifteen to 250 horse-power, and twenty-five cycles, fifteen to 175 horse-power.

THE AJAX LINE MATERIAL COMPANY, Chicago, Ill., has issued bulletin 5, devoted to Ajax outdoor lighting specialties, listing and illustrating a great variety of devices of this character. Copies of this bulletin will be furnished to those interested upon request.

H. G. OSBORNE, 74 Cortlandt street, New York city, is publishing a very interesting booklet describing the Osborne extension brick drill. This drill consists of two parts: a hardened steel "drill head" and a piece of gas-pipe threaded on one end to screw into the drill head for a handle. Some surprising results are claimed for this device.

THE BRISTOL COMPANY, Waterbury, Ct., has published a new catalogue describing its staggered point steel belt lacing. The illustrations show the belt lacing in full size and the pictures are indeed convincing of the utility of this device. This line of staggered point steel belt lacing has been developed to meet the practical requirements of all kinds and widths of belting. They are made in ten different sizes and of different lengths, suitable for every thickness and width from the lightest to the heaviest conveyer belts. For the benefit of any one interested, who is not familiar with the merits of these fasteners, free samples will be sent on application.

THE EMERSON ELECTRIC MANUFACTURING COMPANY, St. Louis, Mo., has ready for distribution a series of bulletins devoted to several of its specialties, as follows: No. 3128, single-phase induction motors, frame 24 FA, one to twenty horse-power, full load, automatic start: No. 3129, single-phase induction motors, frame 28 EA, one to six horse-power, full load, automatic start; No. 3130, single-phase induction motors, frame 32 FA, one to eight and one to six horse-power, condensed type, full load, automatic start; No. 3131, single-phase induction motors, frame 28 JA, one-fifteenth horse-power, light-load start type for intermittent service; No. 3132, single-phase induction motors, frame 28 JB, one-fifteenth horse-power, full-load start type for intermittent service; No. 3906, family sewing-machine motors, for Singer No. 66 drophead machines, for alternating and direct current.

THE CENTRAL ELECTRIC COMPANY, Chicago, Ill., is distributing a booklet entitled "A Few Suggestions on Methods of Constructing Telephone Drop Circuits," and also calling special attention to the company's "Universal" porcelain insulators for this purpose. A considerable number of illustrations are employed, showing the various methods of attaching the insulators to crossarms, poles and walls. Another folder the company is distributing is entitled "Daylight at Night," describing the Columbia tungsten lamps, for which the company is the general western sales agent. This folder gives considerable prominence to the fact that immediate deliveries of these lamps can be made from the Chicago ware house. Data are given as to the watt consumption compared with carbon-filament lamps, this comparison being worked out on the basis of both five cents and ten cents per kilowatt-hour. An attractive thirty-two-page bulletin devoted to lighting fixtures shows a complete line for varied classes of illumination, one section being devoted to tungsten-lamp fixtures. Special attention is called to the fact that the fixtures are produced by the company's new factory organization, this insuring uniform product and prompt shipment. An important feature for those having rush orders is the "boxed" fixtures, comprising certain standard lines, carried in stock for twenty-four hours' shipment. These bulletins and catalogues will be sent to those interested upon request.

DATES AHEAD.

Michigan Electric Association. Annual meeting, Grand Rapids, Mich., August 18-21.

International Association of Municipal Electricians. Annual convention, Detroit, Mich., August 19-21.

Ohio Electric Light Association. Annual convention, Put-in-Bay, Ohio, August 25-27.

Colorado Electric Light, Power and Railway Association, Glenwood Springs, Col., September 16-18.

Illuminating Engineering Society. Annual convention, Philadelphia, Pa., October 6-7.

American Street and Interurban Railway Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Accountants' Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Claim Agents' Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Engineering Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Manufacturers' Association. Annual convention, Atlantic City, N. J., October 12-16.

American Electrochemical Society. Fall meeting, New York city, October 30-31.

Record of Electrical Patents.

Week of July 14.

892,983. MANUFACTURE OF HYPOCHLORITE SOLUTIONS BY ELECTROLYTIC METHODS. William P. Digby, London, England. The decomposition product liberated at the anode and cathode are shielded from the main body of the electrolyte by porous partitions.

893,015. ELECTRIC HEATING APPARATUS. William H. Ripley, Bloomfield, N. J., assignor to the Prometheus Electric Company. A housing for an electric heater.

893,067. TROLLEY-POLE ATTACHMENT. Karl O. Garner, West Alexandria, Ohio. The pole socket is slotted to receive locking projections upon the pole.

893,082. ILLUMINATED DOOR KNOB. John W. Lind, Boston, Mass., assignor to H. G. Williams and J. A. Spiker, Salt Lake City, Utah. A hollow knob with transparent face containing an incandescent lamp.

893,125. SELECTIVE SIGNALING SYSTEM. Garrison Babcock, Chicago, Ill., assignor to Stromberg-Carlson Telephone Manufacturing Company, Rochester, N. Y. A system employing selective devices at substations controlled from the central office.

893,147. APPARATUS FOR SIGNALING AND COMMUNICATION TO MOVING TRAINS. Henry B. De Groot and William A. Kendrick, Washington, D. C., assignors of one-fourth to Henry Copperthite and three-sixteenths to Charles E. Kendrick, Washington, D. C. A system utilizing a signaling circuit and a telephone.

893,151. DEVICE FOR TRANSMISSION TO A DISTANCE OF SOUNDS PRODUCED BY TALKING MACHINES. Eugene Ducretet, Paris, France. A microphone is attached to the horn at the talking instrument.

893,160. ELECTRIC SWITCH. David E. Gray, New York, N. Y. A battery changing switch for effecting series or multiple grouping.

893,163. COUPLING FOR ELECTRICAL CONDUCTORS. William C. Hafemeister, Cleveland, Ohio, assignor, by mesne assignments, to the Van Dorn Electric and Manufacturing Company. A coupling consisting of two similar members with plane faces and interlocking tongues.

893,214. ELECTRICALLY ILLUMINATED DOOR-KNOB MECHANISM. Henry G. Williams and John A. Spiker, Salt Lake City, Utah. A transparent knob enclosing an incandescent lamp.

893,228. DYNAMO-ELECTRIC MACHINE. Gano S. Dunn, East Orange, N. J., assignor to Crocker-Wheeler Company, Ampere, N. J. The reciprocal of the square of the air-gap length bears a constant ratio to the distance along the armature periphery from a fixed point.

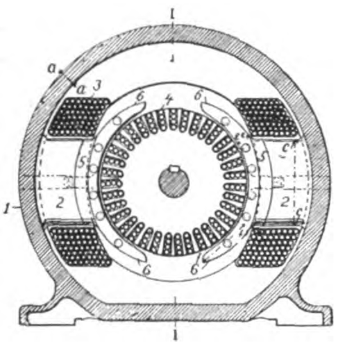
893,244. X-RAY METER. George C. Johnston, Pittsburg, Pa. A fluorescent material casts its light upon a selenium cell in a meter circuit.

893,249. TELEPHONY. Isidor Kitsee, Philadelphia, Pa. A local circuit including an enunciating device indicates the status of the trunk line.

893,250. TELEPHONY. Isidor Kitsee, Philadelphia, Pa. A trunk line closed at both terminals through sources of current in opposition.

893,265. INSULATOR. Augusto Richard, Milan, Italy. An insulator composed of two readily separable parts.

893,278. TELEGRAPHONE. Harve R. Stuart, Wheeling, W. Va. A condenser and battery attached across the recording magnet.



893,228.—Dynamo-Electric Machine.

893,285. ELECTRIC CABLE INSULATOR. Edward M. Tompkins, Chicago, Ill. A petticoat insulator having an axial cavity to receive and hold the cable.

893,286. MULTIPHONE. Kelley M. Turner, New York, N. Y., assignor to General Acoustic Company. A pair of transmitters connected in multiple and attached to a horn having a plurality of receivers.

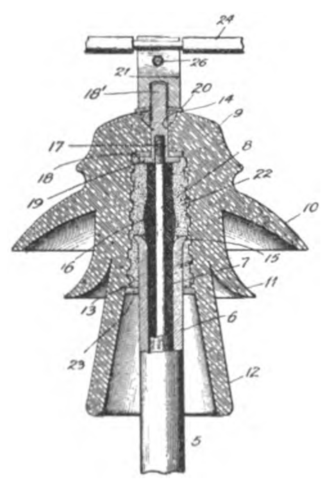
893,305. ELECTROMAGNET. Herbert W. Cheney, Norwood, Ohio, assignor to Allis-Chalmers Company and the Bullock Electric Manufacturing Company. An iron-clad magnet, each of the parts having inserted a plug of higher magnetic retentivity.

893,314. MAGNET-ACTUATED SIGNAL BELL. Harold W. Eden, Detroit, Mich., assignor to P. R. Manufacturing Company, Detroit, Mich. A vibrating call bell.

893,330. SECONDARY BATTERY. John Knobloch, New York, N. Y., assignor, by mesne assignments, to Franz Sigel, New York, N. Y. The elements are built up of a series of perforated tubes enclosing the active material.

893,351. CURRENT DIRECTOR. James F. McElroy, Albany, N. Y., assignor to Consolidated Car-Heating Company, Albany, N. Y. A group of four variable carbon resistances controlling the current through the motor.

893,370. DYNAMO-ELECTRIC MACHINE. Howard H. Ralston, Norwood, Ohio, assignor to the Bullock Electric Manufacturing Company. An adjustable brush gear.



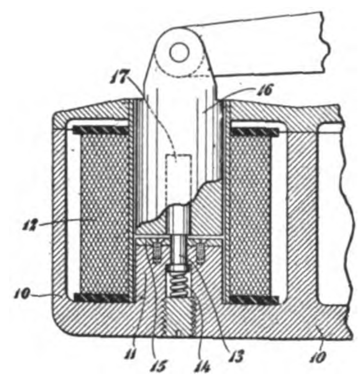
893,285.—Electric Cable Insulator.

893,382. ELECTRIC CIRCUIT CONTROLLER. Dane B. Sawyer, Paterson, N. J. A motor controller having a vertical moving contact bar.

893,402. AUTOMATIC ELECTRIC SIGNAL SYSTEM. Earle Van Briggle, Kokomo, Ind., assignor of one-half to Charles M. Brooker, Kokomo, Ind. A signal controlled by a pair of differentially operating solenoids.

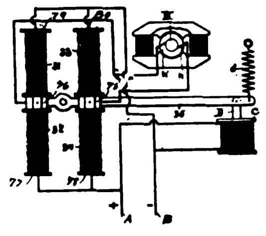
893,414. TELEPHONE SWITCHING AND SIGNALING APPARATUS. James G. Wray, Chicago; Herbert T. Gardner, Maywood, and William G. Kinton, Chicago, Ill., assignors to American Telephone and Telegraph Company. A signaling system for trunk lines.

893,533. ELECTRIC-LIGHTING SYSTEM. James F. McElroy, Albany, N. Y., assignor to Consolidated Car Heating Company. A train lighting system employing a variable-speed magnetically regulated dynamo.



893,305.—Electromagnet.

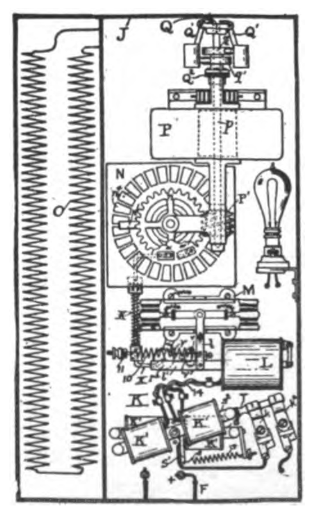
893,534. ELECTRIC-LIGHTING SYSTEM. James F. McElroy, Albany, N. Y., assignor to Consolidated Car Heating Company. A train-lighting system depending for its control on the condition of the battery.



893,351.—Current Director.

893,536. ELECTRODYNAMIC BRAKE. Frederick W. Newell, Hastings-upon-Hudson, N. Y., assignor to Otis Elevator Company, Jersey City, N. J. A brake controlled by a differential relay to prevent generator action of a motor.

893,555. WIRE FASTENER. Cornelius F. Sullivan, Boston, Mass., assignor to Frank W. Lowe, Boston, Mass. A coupling sleeve formed of a spirally wound wire.



893,533.—Electric-Lighting System.

893,565. ELECTRODE. Henry S. Blackmore, Mount Vernon, N. Y. An electrode composed of a metal-carbon-containing compound and a binder.

893,586. THERMAL CUTOUT. Bryson D. Horton, Detroit, Mich. A fuse composed of a group of wires, none of which alone would carry the normal current.

CONTENTS

ELECTRICITY IN COUNTRY HOUSES.

We have not infrequently dwelt upon the advantages of electric power in the home, and we have called particular attention to the conveniences thus obtainable, and to the comfort and cleanliness brought by the introduction of the incandescent lamp and a few little motors. These facts are being realized by many households, and the electrical power is fairly taking up many cares of the home. This is, of course, true only in those localities where cheap electrical energy is obtainable; but in the large cities where modern electrical systems exist, and in those districts near large water powers, the comforts procurable through a well-considered use of electricity, are being realized by a rapidly increasing number of families.

There are, however, large districts where cheap electrical energy is not available. These are usually country places supplied only by small electric systems, or situated so far from the large power-house that the cost of transmission brings the price of electrical energy up to a figure which prevents its general use. In such cases, some other source of energy must be provided if the home is to take advantage of the adaptability of the electric motor. The means by which this may be done are interestingly discussed in an article by Mr. Putnam A. Bates, which appears in the July issue of the Journal of the Franklin Institute. Mr. Bates believes that the electric motor may be used with advantage, not only in the large country home, but the farmer will find that it will solve many of his problems which are now becoming serious. There has been a decided drift of men with some aspiration to become a little better than clerks or bookkeepers, from the city to the country. To support themselves, these men necessarily turn to farming or some other industry which can be carried on there. One of the difficulties with which they have to contend is the securing of competent and reliable help. Mr. Bates believes that a well-planned equipment of electric motors will enable the farmer or dairyman to get along with less help, and will make it possible for him to do much of the work which he could not undertake without some form of mechanical drive. Further, the existence of a source of cheap power will lead to improved methods of farming and dairying. A cold-storage room can easily be fitted up for preserving dairy and farm products; and mechanical devices driven by motors will transform the work of the farmer or dairyman from one of hard labor into one in which his chief duty will be the control and management of various machines. In other words, he will become the superintendent of a special mill, instead of the colaborer with his farm hands, which he was before.

To apply these methods successfully, it is, of course, essential that the cost of so doing shall not be large. It is just here that the main difficulty has lain. Mr. Bates believes that a suitably planned gas-engine-driven dynamo, operated in conjunction with a storage battery, will provide the desired supply, and will do this at a moderate cost. Such an equipment is not difficult to care for and requires little attention, and if intelligently run, would practically take care of itself, with occasional inspection. The batteries would, of course, provide the demand for energy at any time of the night or day; and they can be kept charged by running the generating unit at such times as are convenient. Equipment can, of course, only be installed at some expense, and it is hardly to be expected that every farmer will immediately adopt the system. In some cases co-operation among neighbors might produce the most satisfactory result. But in any case, an equipment of this kind should be carefully designed and not put in haphazard, or left entirely to the judgment of the first salesman who comes along. The farming industry, including all its branches, lies at the foundation of the prosperity of the country; and it will be strange indeed if the use of electrical energy, which is bringing about such important changes in other industries, does not introduce new methods here. The change may be slow in coming, but come it will in time.

JOIN THE INSTITUTE.

Too many of the younger engineers available for membership in the American Institute of Electrical Engineers neglect to join that body and bring to it their support in the form of the small contributions called dues and the resulting increase of membership. They are too apt to take a narrow, selfish view, saying they can get the papers and discussions printed by the Institute for less than the yearly dues and there is, therefore, no reason why they should pay more. Such men fail entirely to realize the advantages which come from merely being a member of a recognized engineering society. Any one who attends any of the meetings of the Institute gets far more out of the discussions than he can from any published report, while the mixing with his brother engineers brings him other returns equally as great. Moreover, the membership list of the Institute to-day is the recognized roll of electrical engineers and every one turns to it to find out where such and such a friend is, or what electrical engineers there are at any particular place.

These, however, are the selfish reasons of belonging to the Institute, and there are many more of them, as well as others more altruistic, which are convincingly presented in the article contributed to this issue by Mr. Charles B. Burleigh. Every electrical man who is not a member of the Institute should read Mr. Burleigh's argument and reflect upon what he says. But there is one reason which perhaps more than all others should induce electrical engineers to support the Institute. This was well stated by Lord Bacon in his Maxims of the Law: "I hold every man a debtor to his profession; from the which as men of course do seek to receive countenance and profit, so ought they of duty endeavor themselves by way of amends to be a help and ornament thereunto."

A NOTEWORTHY ELECTRIC LIGHTING INSTALLATION.

The Union Station put into service in Washington, D. C., recently is probably the most complete building of its kind in the world. Not only its size, but the many kinds of service connected with it presented a number of engineering problems of unusual interest. One of these is that of lighting satisfactorily all parts of this large structure. A year or so ago this problem would have been attacked by a rule-of-thumb method, and the result, which would have been accepted without comment, would probably have been far from satisfactory. But to-day few features of such buildings receive more consideration than the lighting. We have learned how negligent we formerly were in such matters, and are rapidly approaching the point where the general public will be quick to appreciate good illumination. For these reasons the description of the lighting system installed in the Washington station, which is given elsewhere in this issue, will be interesting to many.

The lighting in the small rooms and offices of the station presented no unusual features. Fixtures have been installed here enabling any of the new high-efficiency lamps to be used. One interesting part of the lighting system is that in the ticket lobby, which is lighted by skylights during the day. Here high-candle-power tungsten lamps have been placed above the skylights so as to give an illumination representing as nearly as possible that provided during the day. This plan has been tried elsewhere, with very good results.

Another difficult room to light is the main waiting room, a room 120 feet wide by 230 feet long, with an arched ceiling ninety-eight feet above the floor at the highest point. The architectural design of this room offered an opportunity for indirect lighting by means of lamps placed behind the galleries on the sides of the room and over colonnades connecting the galleries at the ends of the room. By using inverted open-arc lamps with screens of tinted glass, corrugated reflectors and magnetic deflectors throwing the arc toward the room, which produce a uniform illumination of the ceiling, a very fine effect has been secured. There is ample illumination for reading at every part of the room, so that no other fixtures have been necessary. The objection so often found with such systems of illumination, namely, that the intensely lighted ceiling is hard on the eyes, will hardly hold in this room, because of the shape of the ceiling and its height above the floor.

A third difficult room to light is the main concourse, a space 755 feet long by 150 feet wide. This is lighted during the day by skylights; and the same scheme found satisfactory in the ticket lobby was tried. Due, however, to the structural steel work supporting the roof, this was unsuccessful, there being too many shadows cast upon the skylights. The plan finally adopted was the hanging of direct-current arc lamps seven feet below the ceiling. The height of these lamps above the floor enabled a uniform distribution to be obtained, and places them out of the direct line of vision. There are other interesting features about this installation which are well worthy of careful study.

ELECTRIC CABS.

A few years ago a number of electrically propelled cabs were put in service in London, and great hopes were expressed that they would solve, in part, at least, the difficult problem of handling London traffic. The advantages of a quiet, clean and easily controlled vehicle were fully explained at that time, and all that was needed to give the electric cabs a permanent place on the London streets was a practical demonstration of the cheapness of this method of transportation. Unfortunately, it was just here that the cabs failed, and after a time they were retired from the streets.

Now again we learn that the electric cabs are about to be given another trial in London, and it is to be hoped that they will be more successful this time than before. Doubts are expressed, however, in some quarters because the preliminary estimates of the cost of running the cabs and the probable traffic they will secure do not seem to be sufficiently conservative. The cabs are expected to make about thirty-seven miles a day and to earn $10. This is at the rate of twenty-five cents a mile, including the unproductive mileage, and it is thought that this estimate is much too high. On the other hand, the cost of charging and maintaining the batteries would be about six cents a mile, and cost for repairing tires three cents a mile, and the other items of cost are in proportion. The first cost of the cabs, including batteries, but not tires, will be $2,100. Under these conditions success seems rather problematic.

However, electric cabs have been found successful elsewhere where the conditions are more favorable. There would be a much better chance to keep them on the London streets if they could make fifty or sixty miles a day, but at the comparatively low fares which are charged in London the outlook for success is none too good. There is no doubt that the electrically propelled vehicle is much the most suitable for city service. It is noiseless and under better control than any other; it can quickly take advantage of openings in the traffic and it leaves behind it no offensive trail. For use in the country it is handicapped by its limited range of travel, but in city work this disadvantage is largely removed. The electric cab will doubtless come to its own in London before long, but under the present conditions it will have much to contend with.

SCIENTIFIC SYMBOLS.

On another page of this issue we publish a communication from Mr. Miles Walker, on the subject of scientific symbols. This has been prepared at the request of the British Electrotechnical Commission, in view of the fact that different symbols are employed to represent the same thing in different countries, and the great difficulty of securing uniformity in this matter. The old and very good custom of employing the initial letter of the name as a symbol for the thing is not without faults, because the various quantities have different names in different languages, and hence the symbol in one language does not conform to the name in another. Moreover, when such symbols are employed, it may be necessary to use the same letter for a number of different quantities: hence has arisen the practice of indicating which quantity is represented by adding a subscript or accent to the symbol—an undesirable complication. On the other hand, when arbitrary letters are employed as symbols there is nothing to indicate for what they are intended, so that they must be memorized.

For these reasons Mr. Walker does not think that a modification of the present system of using letters as symbols, even though uniformity could be secured, is quite satisfactory. He therefore suggests arbitrary signs, each having some significant shape which will make it easy to remember; and in his communication he suggests a number which are unquestionably appropriate. In proposing these Mr. Walker considers not only the reader and the writer, but also the printer, and he says he has found that the latter would not be much opposed to the addition to his numbers of types. There would be objection with machine composition. But even at the present time all formulæ and other parts of articles employing special type must be set up by hand. This not only occasions delay, but complicates the work. In this respect, of course, the suggestions would not put us in any worse position than we are in at present, as even the use of accented letters very often calls for hand composition; but it is unfortunate that some plan can not be suggested which would avoid this objection. It is the only one we can see to the proposed scheme; as certainly the use of a significant symbol which can mean nothing else, and which is easily remembered, has much to commend it.

THE GROWTH OF THE ALUMINUM INDUSTRY.

One of the triumphs of applied electric chemistry has been the adding to the materials of the engineering world a new metal having very valuable properties. Prior to the introduction of the electrolytic methods of producing aluminum it was reduced from one of its compounds by the use of metallic sodium. The production then was but a few pounds a year, the metal being used for a few very special purposes where lightness was essential, and to supply chemical museums. In 1883, for instance, but eighty-three pounds of this remarkable metal were produced in the United States, although at that time its virtues were fully appreciated and there was no lack of raw material. The cost of production, however, placed it beyond consideration for mechanical purposes.

The introduction of several electrolytic methods of extracting aluminum from its ore at once raised the metal to an important position in the mechanical world, simply because the cost of production, and hence the price of the metal, were very greatly reduced. Thus by 1890 the output had increased to 61,000 pounds in this country alone; the following year it jumped to 150,000 pounds; four years later, in 1895, it was over 900,000 pounds, and it passed the million mark the following year. In 1900 over 7,000,000 were produced and in 1904 8,600,000 pounds were consumed. Last year the consumption was over 17,000,000 pounds, making the total production in this country since 1883 over 100,000,000 pounds. This has been indeed a most noteworthy growth of a new and important industry.

LORD KELVIN'S PHILOSOPHY.[1]

EXPLANATION IN TERMS OF FORCE OR OF MOTION? ACTION ACROSS EMPTY SPACE OR THROUGH A MEDIUM?

BY SIR OLIVER LODGE.

One of the most interesting and important outcomes of last year's meeting of the British Association at Leicester was the declaration by Lord Kelvin, during a memorable discussion on the constitution of the atom, in Section A, that he had found it necessary to abandon the attempt to contemplate the material universe explicitly in terms of æther and motion, and for his own part preferred to resort to the Boscovich doctrine of centres of force acting on each other according to some curiously complex law, without specific attention to the hypothetical medium in which such forces may exist.

Now undoubtedly these ancient postulates of matter and force represent the dynamical method first made feasible by Newton's achievement in celestial physics, whereby phenomena were correlated by unexplained particles of matter acted upon by unexplained forces, of statical origin and unknown mechanism, according to a specified law of distance. This was how Newton successfully solved the problems of gravitation, and constructed the working theory of astronomy; but it had been hoped, and by some is still hoped, that the time had now come for seeking to represent, in terms of something simpler and more fundamental, the nature of matter and the origin or inner mechanism of its various forces.

The most powerful and hopeful lever wherewith to attack this great philosophical problem was the kinetic theory of elasticity and rigidity, introduced by Lord Kelvin himself. By this means it has been hoped to express force in terms of the still simpler conception of motion; in fact, to explain all the forces with which physicists have to do—electrical and chemical attraction, elasticity, magnetism, cohesion and perhaps gravitation—in terms of the internal motions of a universally connecting fluid plenum.

But now the question arises, Is it at all certain that the material universe can really be understood in terms of motion alone—motion of an all-pervading continuous fluid known as the æther of space? And would such a solution be satisfactory?

To many it has seemed that this reduction to simplicity was the closest approach to ultimate explanation and unification that could be hoped for in the domain of mathematics and physics; and during the last half-century many steps, apparently in the direction of such an achievement, have been taken by the leaders in these branches of human knowledge.

The mathematical foundation was laid by Helmholtz when he reduced rotational or vortex motion in perfect fluid under the domain of mathematics; it was followed up by Lord Kelvin's kinetic or gyrostatic theory of elasticity and rigidity; so that mathematicians, such as FitzGerald, Heaviside, Larmor, Hicks, J. J. Thomson and others, as well as Lord Kelvin himself, have, from various points of view, endeavored to devise a scheme of spinning motion in a perfect fluid plenum which should be able to accomplish in general terms all that the æther is known to perform: more particularly that it should be able to imitate its faculty of transmitting the transverse or solid quiverings that we call light, yet without resisting the motion of bodies through it; and at the same time that it should be able to maintain its own turbulent or whirlpool motion in an unconfused and regularly stable condition throughout infinite time. And in this difficult undertaking they have from time to time seemed partially successful; at any rate, they have reached suggestive results and opened up stimulating vistas.

The æther must be incompressible, too, being perfectly continuous without breaks or any kind of atomic or granular structure, save such as may be conferred upon it by reason of its infra-material internal motion. An infinitesimally turbulent liquid of some kind seemed the desideratum, and many have been the attempts to devise such a liquid. An interlaced system of vortex fibres or filaments has to some seemed the most likely device; a similar scheme was a system of plates or laminar vortices; while a third modification conceived it as a collection of connected filaments all in a state of rapid internal motion, though stationary as regards locomotion in space—what might be called a vortex sponge. By some such means it was hoped to be able to combine the elastic rigidity appropriate to a solid, with the penetrable unresistance to motion of solids through it, characteristic of a perfect fluid, and with the complete incompressibility of an ideal liquid. But the mathematical difficulties of all such treatment have been rather overwhelming; and an uncertainty about the stability or permanence of such a medium has always obtruded itself in a discouraging manner.

In fact, there has always been a troublesome amount of instability in all the schemes that have hitherto been devised, so that none of the expounders of the motion doctrine was able to announce a finally satisfactory result.

Still it was felt by most of those who have worked at the subject that the outlook in this direction would be so bright, if initial difficulties could be overcome, that it was worth a long-continued effort to see if a coherent scheme could be planned on these lines, so as to secure what, if it turned out to be the truth, would surely be a magnificent generalization.

Indeed, it has sometimes seemed unlikely that a mode of explanation which offered such attractive features, and led so far in the right direction, could, after all, be a blind alley leading nowhere; or, to vary the metaphor, a mere will-o'-the-wisp which it was waste of time to pursue.

What has certainly been made out is that motion of atomic structures, in an æther with elasticity postulated, supplies a complete working scheme on which we can rest without inquiring further as to the origin of this elasticity. Beyond this, the attempt to explain the material universe on a purely kinetic basis has not made much progress in quite recent years; and, to those competent to attack it, it has probably seemed better to let the problem lie dormant for a time, until future discoveries in mathematics or in physics throw more light upon the rocky path or provide us with better instruments for climbing it.

During the epoch of waiting it now appears that our venerated chief was deflected from further attempts in this direction, and directed his attention elsewhere. Other methods seemed to him more immediately hopeful; and whereas it had been hoped to explain force in terms of latent motion, Lord Kelvin in later years sought to expound motion in terms of force, giving up the kinetic unification of the material universe in favor of a conception more arbitrary and descriptive, and permitting himself to regard force as perhaps an equally fundamental, perhaps a more fundamental, conception than motion.

It may be that philosophers will concede the (to me) somewhat improbable proposition that an explanation in terms of force and action at a distance will be as satisfactory as an elucidation in terms

[1] Being thoughts suggested by the meeting of the Mathematical and Physical Section of the British Association at Leicester in August, 1907; and referred to in Sir Oliver Lodge's recent presidential address to the Faraday Society, May 26, 1908. From *Nature*, London, July 2.

of motion and a continuous medium. To Lord Kelvin it would appear that both solutions were equally satisfactory, and that it was only a question of which was the more tractable. In any case it is noteworthy that he took up so clear and definite a position; it is the key to much of his recent work, and to the difficulties which he felt in accepting some of the hypotheses which are a natural consequence of the electrical theory of matter and of some of the facts of radioactivity. It now seems not unnatural that he should have sought to express and explain these great results otherwise. His attitude is both coherent and reasonable; though I would urge that most theoretical advance and discovery (in the hands of Maxwell and others) has been along the continuous and medium line, which, if not the line of ultimate explanation, is at any rate that of achievement.

At the same time it must be admitted that, if a longitudinal impulse is transmitted by an incompressible medium at an infinite pace, the process becomes barely distinguishable from action at a distance, through a force varying according to a specified law. Or—putting what is virtually the same thought in another way—the influence of an electron, or matter unit, whose field of force extends infinitely in all directions, need not be conceived as limited by some arbitrary boundary beyond which things can be said to be at a distance from it.

It will be remembered that some of the old philosophers saw great difficulties in the abstract conception of motion. It appears as a curious evanescent transition from one place to another, involving the attribute of "time"; it is indeed "not a being but a becoming," when position is taken as the primary conception.

But I urge that it is simplest to regard "position" and "distance" as secondary conceptions, subordinate to and arising out of our perception of motion. Unless motion is supposed to be a thing directly apprehended, it is truly rather an elusive idea. To me it seems a direct apprehension—direct information conveyed by our muscular sense. Space itself seems a consequence deduced from our perception of motion; and the idea of time follows from our direct perception of rapidity of motion. But probably to Lord Kelvin these things appeared otherwise.

The conclusion of the discussion on the constitution of the atom may be summed up thus:

The internal energy of Lord Kelvin's model atom is static or potential. The internal energy of the hypothetical atom at which others are working is kinetic.

The disintegration of radium in the former case is comparable to the explosion of an unstable chemical compound, like guncotton. In the latter case it must be represented by something more akin to the flying to pieces of a single rapidly spinning unit, such as a flywheel.

And so for the present the matter stands.

The New British Patent Act.

The effects of the new patent act, which compels foreigners exploiting patents in Great Britain to manufacture the article mainly in that country, have come as a great surprise to many manufacturers here, says the New York *Journal of Commerce*. It is understood that the full advantage is likely to be taken of the clause which advocates the legal protection of foreign patents after August 28. Such patents may be revoked on application by any person to the Comptroller of Patents if granted four years ago to any foreigner who manufactures exclusively or mainly outside of the United Kingdom.

Already a large number of foreign firms have secured factory sites, and a syndicate of German chemical manufacturers has taken a site of twenty-four acres in the vicinity of the Mersey, while a large German electric company is negotiating for another large site, and many foreign inquiries for sites in the Manchester district are being received. The Hoechst Farbwerke and Messrs. Cassella & Company are building a factory for dye manufacture at Ellesmere Port, situated upon the Manchester Ship Canal.

The Board of Trade states that last year 2,608 patents were granted to Germans and 2,792 to Americans by the British Patent Office. Sir Joseph Lawrence, who, with Ivan Levinstein, framed the act, gives the following summary of the effects of the former laxness of the British patent laws:

Estimated British loss by diversion of aniline dye industry, from £5,000,000 to £20,000,000 per year. German chemical industry, yearly overturn, £70,000,000. Amounts paid to foreign countries for telephone apparatus, £10,000,000. Yearly amount of wages lost in telephone industry, £500,000. Value of imported motor cars and cycles in the last three years, £5,500,000.

An English trader taking out a patent in Germany must work it in that country, so that the German has little to complain of if the same regulation is applied to him. Some German patentees will get English firms to manufacture their goods, but that also will mean a great increase in wages, etc., for English work people. Thousands of firms on the Continent and in America must either take this course or build factories in England if their British trade is to be maintained. France will be affected in its motor-car trade, but the chief sufferers will be Germany and America.

National Fire Protective Association on Incandescent Lamp Hazard.

The Underwriters' laboratories have issued the following bulletin dealing with the hazard of exposed bases of certain incandescent lamps:

"For the proper safeguarding of life and property the National Electrical Code prescribes that no live parts of an incandescent lamp base shall be exposed when the lamp is in the socket. Underwriters' laboratories and manufacturers of sockets, receptacles and incandescent lamps have co-operated for several years for the establishment of standards whereby this result has been accomplished for the bases of common carbon filament lamps. The newer high-efficiency lamps, such as the tantalum and tungsten, require a metal extension or 'skirt' over the bulb beyond the Edison screw base. Designs have been developed and adopted by American manufacturers for constructing these high-efficiency lamps in such a manner as to insulate this skirt from current-carrying parts of the base and so secure in these types the same degree of protection as that already obtained for the older patterns. Some of the foreign manufacturers are, however, supplying lamps having exposed skirts not insulated from the circuit.

"Your attention is respectfully called to the desirability of giving preference to lamps having no live metal parts exposed when placed in the standard socket, which has a depth of fifteen-sixteenths inch in a vertical plane from the bottom of the centre contact to the upper edge of the outer socket shell or wall."

In the equipment of manufacturing plants one of the most interesting features, during the past two years, has been the introduction of steam turbines into a great variety of industries, from factories of different kinds, where about the same quantity of power is used continuously during the day, to cement plants, steel mills, smelters, etc., where the load fluctuates violently from one moment to another. Flour-mill and sawmill operators were among the latest to join the procession of turbine users, and now a tannery—one of the largest in the world—the Pfister & Vogel Leather Company, has just ordered two Allis-Chalmers turbine units, each of 1,500 kilowatts capacity, or a total of 4,000 horse-power, for the new plant to be built in Milwaukee. Another unit of the same size has been purchased by the Pueblo & Suburban Traction and Lighting Company, Pueblo, Col., and the city of Holland, Mich., will install one of 750-horse-power capacity.

SYMBOLS FOR PHYSICAL QUANTITIES.

BY MILES WALKER.

It is very desirable to have a notation for the representation of physical quantities in scientific books and periodicals which shall be the same in all languages.

The subject is under the consideration of the International Electrotechnical Commission with a view to international agreement, and committees in the different countries (in England under the chairmanship of Lord Rayleigh) are discussing this particular subject. They are dealing more especially with symbols for electrical and magnetic quantities, but the system might with advantage be extended to embrace all important quantities in physical science, especially as the subject is receiving the attention of most technical societies with a view to some action being taken in the matter.

There are, however, two great difficulties which arise when we try to fix upon a standard notation.

The first is the difficulty of persuading a number of writers and readers who have become accustomed to a certain symbol for a certain quantity to change it in favor of an equally large number of writers and readers who have become accustomed to another symbol.

In the second place, there are not enough letters in the two or three alphabets at our disposal to give a distinct symbol to each quantity without resorting to the combination of more than one letter to form a single symbol. There is a great objection to this combination of letters because the use of sub-script letters and numbers is required for distinguishing between particular quantities of the same general kind.

There is, moreover, an objection to using letters at all to represent quantities in a universal notation because, unless initial letters are used, there is no connection in the mind between the letter and the quantity, and the symbol is difficult to remember. We can not always use initials because the initial letters differ in different languages. Moreover, the same initial occurs for a great number of different quantities.

One way of avoiding the above difficulties would be to create a number of new symbols which could be printed by means of type like ordinary letters, and which would represent each physical quantity in a distinctive manner.

The question, however, arises as to whether a number of entirely new symbols would be acceptable to writers, readers and printers alike, and the subcommittee on symbols appointed by the British section of the commission has requested the writer to place his views publicly before the profession with a view of obtaining suggestions and criticisms as to the feasibility of such a scheme from as wide a circle as possible.

In choosing a symbol we would try to make a very simple picture of something that reminds us of the quantity in question. For instance, ⫰ might represent temperature. If we were told that this simple outline of a thermometer represents temperature we would have no difficulty in remembering it. Similarly, / might represent force, and the various "forces" might be derived from it; for instance, ϟ electromotive force (conventional representation of lightning), and ∩ magnetomotive force.

It is not my purpose here to say what would actually be the best form of symbol for each quantity, but it is not a difficult matter to devise very simple characters which can be written quickly, easily and with sufficient accuracy, and which can at the same time assist the memory to connect them with the quantity for which they stand.

What would the printers say to the new type? The author has taken up this matter with a very large publishing firm, and is assured by their chief expert that 200 or 300 new type would be a small matter to a modern printer, who is already accustomed to deal with many hundreds of different fonts, each of which contains from thirty to 120 different symbols. He estimates that a printer in a large way of business has at his command as many as 60,000 distinct type, differing from each other either in letter, size, body or face. The addition of 200 or 300 more would be a drop in the ocean. The size of the new type could be standardized for most purposes, and it would only be in some special case that another size would be called for.

The setting up of the formulæ with the standard size of type would be simpler than with the present system, in which sub-script letters are often unnecessarily introduced. One symbol under the present system sometimes consists of four or five letters.

If it be admitted that the introduction of new symbols is advisable, the question arises what shall the new symbols represent exactly? Shall the sign ⫰ (Temp.) represent temperature in any units, or shall it represent the number of degrees of temperature, measured by some scale agreed upon, and embodied in the definition of the symbol? If the system of units employed be not prescribed, fewer symbols would be required, and the general writer who now says vaguely "Let T equal the temperature" would find the symbol sufficient for his purpose. But from the reader's point of view there is much to say in favor of a symbol which will embody in its definition a standard system of units. Any formula expressed in such symbols would be completely self-contained and would be an exact statement of a physical fact. Until the units employed in any formula are known, the formula expresses only half its meaning. Perhaps some slight addition to the symbol, or even to the whole formula, might be used to indicate that the standard system of units is employed. Without that addition the symbol would have a general meaning. For instance, ⫰ might equal temperature, while ⫰ might indicate the degrees centigrade above the absolute zero. The name of the type might be the name of the physical units which it represents; for instance, for ϟ we might read "volts."

If writers, printers and readers who have any definite views as to the best method of devising a system of symbols would communicate with the technical press, or with the author, they might assist in solving the many difficulties which arise in connection with this matter.

The Cottage, Leicester road, Hale, Altrincham, England.

Aluminum Industry.

The magnitude of the aluminum industry is shown by the following, which gives in pounds the production in the United States since the beginning of the industry in 1883:

1883, 83; 1884, 150; 1885, 283; 1886, 3,000; 1887, 18,000; 1888, 19,000; 1889, 47,468; 1890, 61,281; 1891, 150,000; 1892, 259,885; 1893, 333,629; 1894, 550,000; 1895, 920,000; 1896, 1,300,000; 1897, 4,000,000; 1898, 5,200,000; 1899, 6,500,000; 1900, 7,150,000; 1901, 7,150,000; 1902, 7,300,000; 1903, 7,500,000; 1904, 8,600,000; 1905, 11,347,000; 1906, 14,910,000; 1907, 17,211,000; total, 100,530,779.

The value of the exports of aluminum and manufactures of aluminum of domestic production for the last four years has been as follows: 1907, $304,938; 1906, $364,251; 1905, $290,777; 1904, $166,876.

The Copper Situation.

A sale of 1,000,000 pounds of electrolytic copper was made recently to a large corporation on a basis of eleven and seven-eighths cents per pound. The contract calls for delivery within the next two months.

Copper producers and selling agencies declare that the demand for copper shows some improvement locally. Many of them are of the opinion that a buying movement of some proportions from local consumers will be under way before the close of the year. The increase in orders for electrical equipment indicates a large consumption of copper.

The falling off in production in June was due largely to the big decline from Butte, a fifty per cent shrinkage, compared with May, by reason of the flood. The Butte output amounted to but 13,000,000 pounds, against 26,000,000 a year ago. With the Greene-Cananea still closed down, Mexico likewise continues to show a large decrease.

The shortage of 118,000,000 pounds of copper during the first six months of this year, as compared with two years ago, under high copper prices, must, of necessity take care of a large portion of the decrease in consumption in this country; and it helps to sustain the claim that with any improvement in business, and a stocking up by the large consuming interests, a scarcity of available copper might quickly develop.

A new source of copper supply comes in this month, namely the Ely district of Nevada. After an expenditure of over $15,000,000, the concentration of Ely ores is now taking place, and the smelter will blow in some time this month, so that from now on Nevada will figure in copper production. That state, however, will not be able to supply over 20,000,000 pounds this year, so that with a decrease already of 95,000,000 pounds this year the supply of copper will not do much to fill up the gap.

A careful canvass, made about a week ago, of all the available supplies of copper to be had of the New York selling agents developed the availability of only 5,000,000 pounds of copper at thirteen cents per pound and under. This has since been licked up, so that there is no electrolytic to be had in quantity under thirteen cents per pound. Lake is still quoted at thirteen cents.

The General Electric Company has recently contracted for several million pounds of copper at thirteen cents per pound. It bought the Lake brand, something which it never does if electrolytic can be had for less money. This copper was bought for delivery in September and October.

One of the largest producers of copper in the country says: "While I have been lukewarm with regard to the possibility of anything approaching a stampede among copper buyers, on the ground that a readjustment of the general business situation would be a matter of many months, I am to-day firmly convinced, after a thorough study into the conditions existing here and abroad, that there is every chance of another runaway market in copper after Taft is elected.

"Many buyers will postpone the placing of their orders until the election of Taft has been actually accomplished. It isn't enough for them to be confident of another Republican victory, they must read the returns.

"I notice there is considerable talk of large accumulated supplies in this country and particularly abroad. That is all humbug. Suppose the amount of stock in foreign warehouses is at the highest figures for several years and stands at 37,000 tons; what does that amount to? These figures, applied to the world's necessities, represent but a few days' supply.

"Then again there is a tendency to underestimate the present American consumption because comparison is made with the very excessive and abnormal consumption of 1906 and the first half of 1907. Compare the present consumption with 1905, or any normal period, and it will be found that the amount of copper to-day going into the manufacture of all sorts of brass and copper goods compares very respectably with former years."—*Wall Street Journal.*

The Electrical Equipment of the Royal Mint, London.

A description is given here of the electrical equipment of the Royal Mint in London, England, which has replaced the old mechanical drive installed in 1882. The old arrangement consisted of a number of underground shafts connected with the various machines through gearing and, until 1905, it served to drive the greater number of machines in the mint. As extensions to the mint had became necessary the losses due to the shifting became excessive so that the whole was converted over to the electric drive, the power being supplied to the various motors from a steam-driven generating plant, which takes the place of the old engines. This plant comprises two 200-kilowatt, direct-current generators connected to high-speed engines. There is in addition a small gas engine driving a fifty-kilowatt generator for use when the steam plant is not in service and for charging a storage battery. The latter is rated at 5,000 ampere-hours, at an eight-hour discharge, and built up of fifty-eight cells. Ventilation in this room is provided by grate openings in the walls, in place of windows. These batteries carry all the lighting when the generating plant is not in service and are capable also of carrying a considerable motor load. Lighting and power mains are kept as far as possible distinct. Until 1907 the average monthly output of the generator was 19,600 kilowatt-hours. There are sixty-four motors in the mint and the combined rating is 600 horse-power. A few typical applications are as follows: A fifteen-inch rolling mill is driven by a seventy-horse-power motor through a spur gearing, and the cutting machines are driven from two line-shafts each belted to a ten-horse-power motor. In the annealing room the gas-heated rotary furnaces are turned by motors rated at one to ten horse-power. The coin-press room contains nineteen presses driven through a line-shaft by a thirty-horse-power motor. There are a number of counting machines driven by motors rated at two or three horse-power. —*Electrical Review (London), July* 10.

Power for Montana Mines.

Various financial and mining interests, including Senator Clark, H. H. Rogers, ex-Governor Hauser and others who represent the Missouri River Power Company, have arranged with the Stone & Webster Engineering Corporation, of Boston, for the development of the extensive water-power resources on the upper Missouri River in Montana, on a scale exceeding anything that has been undertaken in this country since interest in large developments began to lag over a year ago. The plans provide ultimately for the generation of 50,000 horse-power by means of two dams and power plants.

It is estimated that the construction work planned will cost $3,000,000, and it will be done in two stages: the first will be the building of a concrete dam to afford 20,000 horse-power at Hauser Lake, sixty miles from Butte. This work will be begun by the contractors immediately.

Subsequently it is planned to build a new concrete dam about 1,800 feet long and 110 feet in height, together with a 30,000-horse-power hydroelectric plant at Wolf Creek, a few miles above Hauser Lake. From this plant the power will be transmitted at a high voltage to Butte and to Helena.

The Electric Lighting System of the Washington Union Station, Washington, D. C.

THE Washington Union Station, Washington, D. C., which has just been completed, presents some very interesting problems in lighting and power requirements. The property consists of: The Union Station, said to be the largest and most magnificent railroad station in the world; Express Building, occupied by the Southern, Adams and United States express companies; power plant, locomotive and car repair shops, coach yard and several signal towers.

The power plant supplies electric current for light and power, steam for heating, compressed air for cleaning, brake testing, signals, etc., and water for drinking, house service and fire protection, to the station, express building and adjoining yards and also light and power to the coach yard, repair shops and signal towers. Separate power plants furnish heat, compressed air and water service to the shops and coach yard.

Service connections from the power plant to the express building and station are made through a pipe subway or tunnel. Piping for water, heating and refrigerating service is carried on supports suspended along the centre line of this subway while vitrified tile ducts, with manholes at convenient intervals, are built into the wall for the electric service.

Cables for electric service north to the coach yard, repair shops and signal towers, are carried through a line of vitrified tile ducts laid in concrete between the tracks. Concrete manholes provided with cast-iron covers, are located from 250 to 300 feet apart on straight runs, and at convenient points where the duct system crosses streets. Manholes are connected to the general drainage system.

The best of materials only is used in the lighting and power systems in order that they shall be as lasting as the building construction. Conduit furnished by the Safety Armorite Conduit Company, electro-galvanized both inside and outside, is used throughout, the smallest size installed being three-quarters-inch. In the inspection of conduit the specifications, with reference to weight and dimensions, were very rigidly enforced, the requirements in this respect being the same as for standard weight steam pipe. All short-radius bends were factory made and galvanizing was performed after bends were formed. All other bends were made by hand in the field and the heating of conduit for this purpose was prohibited.

Outlet, junction and all boxes for low-tension service are of heavy cast-iron construction. In many instances it was thought advisable to use specially designed material and apparatus in order to provide a lighting and power system in keeping with the other construction. Threaded connections, reinforced by locknuts and bushings are used throughout between conduit and outlets in order to provide a continuously grounded system. In addition, the conduits are brought into contact with the steel framework of the buildings and at transformers, the neutrals of which are in every case grounded, a common ground connection is made.

The high-tension distributing system for incandescent lighting and power purposes is operated at 2,300 volts and sixty cycles. Each transformer for lighting purposes and each set of transformers for power purposes is served by an independent cable direct from the switchboard at the power-house. Cables for arc service have either four or eight conductors and serve from two to four loops. All motor-driven apparatus is operated from three-phase lines while all incandescent lighting service is taken from one phase of the generators in order to secure as good regulation as possible and to simplify the wiring.

All cables running north to the coach yards, shops and signal towers are lead-covered on account of the presence of moisture in the duct system. Those to the south are double-braided only, as the ducts in the wall of the pipe subway are reasonably dry and are protected from moisture. The single and three-phase, 2,300-volt cables are insulated with varnished cambric over a thin layer of unvulcanized rubber. These cables were subjected to and successfully withstood a test of 7,500 volts for five minutes between conductors, and between conductors and ground, after being submerged in water for twenty-four hours at the factory, and 5,000 volts for five minutes between conductors and the ground after being installed. Insulation resistance averaged well above 150 megohms per mile. The arc cables, both four and eight-conductor, have each conductor insulated with rubber with varnished cambric over all. These were made up to withstand a test of 10,000 volts at the factory and 8,000 volts after being installed under the conditions mentioned above. Insulation resistance averaged about 4,500 megohms per mile. All high-tension cables were furnished by the General Electric Company.

General Electric new type H transformers, with a ratio of ten to one, are used and are placed in fireproof vaults located at convenient points in the basement of the various buildings. The vault walls are of brick and are built solid from the floor to the ceiling. The floor space generally covers an area of about 100 square feet giving sufficient room for the changing of transformers and parts without disturbing transformers in service. Vault doors are constructed of iron lined with asbestos, and are equipped with lock and keys, and are of sufficient height and width to facilitate the removal of apparatus.

FRONT VIEW OF UNION STATION, WASHINGTON, D. C.

The high-tension cables in each vault terminate at a set of disconnecting switches mounted on the wall above the transformers. Expulsion type fuses are installed between the switches and transformers. Low-tension feeder distributing panels, encased in quarter-inch sheet-metal cabinets, are mounted on the outside of the vault walls at either side of the door, connection to the transformers being made through iron-pipe conduit.

Three-wire, 113-226-volt feeders are run from the feeder cabinets to distributing cabinets located at convenient points throughout the buildings, each feeder serving from one to five or six distributing cabinets. Distributing panels are encased in heavy sheet-metal cabinets and are equipped with three-wire busses and two-wire branches. Feeder circuits, buses and branch circuits are invariably controlled by knife switches, branch circuits being protected by plug fuses and buses and feeders by type A fuses. To secure mechanical strength no switches smaller than twenty-five amperes are used on branch circuits or smaller than 150 amperes on main circuits.

After a number of distributing cabinets had been installed a change was made in the District regulations to permit the grounding, under certain conditions, of all electric fixtures not connected to gas piping. The general scheme of wiring was accordingly changed to profit by this change in regulations. All insulating joints are eliminated entirely. The neutral wire of the branch circuits is grounded to the conduit system at both the fixture outlet and the distributing cabinet—at the latter by means of a copper wire running entirely around the panel in the wiring space and connected with each neutral wire and the conduit system. The neutral wire of feeder circuits is also grounded to the conduit system at cabinets and at transformers by means of a ground plate laid in charcoal under the vault floor. Neutral fuses in all feeder circuits are eliminated and solid copper bars substituted.

Concourse Lighting, Union Station, Washington, D. C.

West End of Waiting Room and Ticket Lobby, Union Station, Washington, D. C.

Okonite compound, of the thickness called for under United States navy yard and dock specifications for low-tension wires, is used for insulating all the secondary wires. Feeders and tie lines are single-conductor and branch circuits twin-conductor. No electrical tests were required prior to installing. After installing, tests for insulation resistance gave results from three to twenty times greater than called for by the District regulations.

The lighting of large floor spaces is generally accomplished by the use of series direct-current arc lamps. General Electric form 10 and 11 lamps are used throughout and are suspended from cone-shaped insulators screwed into the outlet boxes. Loops from the power-house control from twenty-five to thirty-seven lamps each, individual groups being controlled by Gilbert porcelain cutouts enclosed in cast-iron cases conveniently located. Solid No. 8 wire, insulated with Okonite compound and run in one and one-quarter-inch conduit is used for arc service.

All other lighting, except that in the ticket lobby, which is furnished by tungsten lamps, is furnished by metallized carbon filament lamps.

In selecting the lighting units for each particular case, careful consideration was given to the relative efficiencies, reliability and maintenance costs of all commercial lighting units, the conclusion being based upon data obtained from laboratory tests and from many installations in operation.

UNION STATION.

The Union station, passenger concourse, and train sheds cover a ground space of more than eighteen acres. Thirty-three tracks, served by nineteen platforms, enter from the north. Thirteen merge into two which continue to the south under the station and through twin tunnels running between the Library and the Capitol under First street. The sub-basement and concourse basement are used for baggage purposes. The station basement is occupied by a portion of the ventilating and other service machinery and several transformer vaults, the balance of the space being held in reserve for future requirements. The first or street floor is occupied by the main waiting room, ticket offices, baggage room, dining and lunch rooms, women's room, smoking room and state apartments. The kitchen is located on the second floor. The balance of the second floor, the third, and a part of the attic floors are used for office purposes.

MAIN WAITING ROOM.

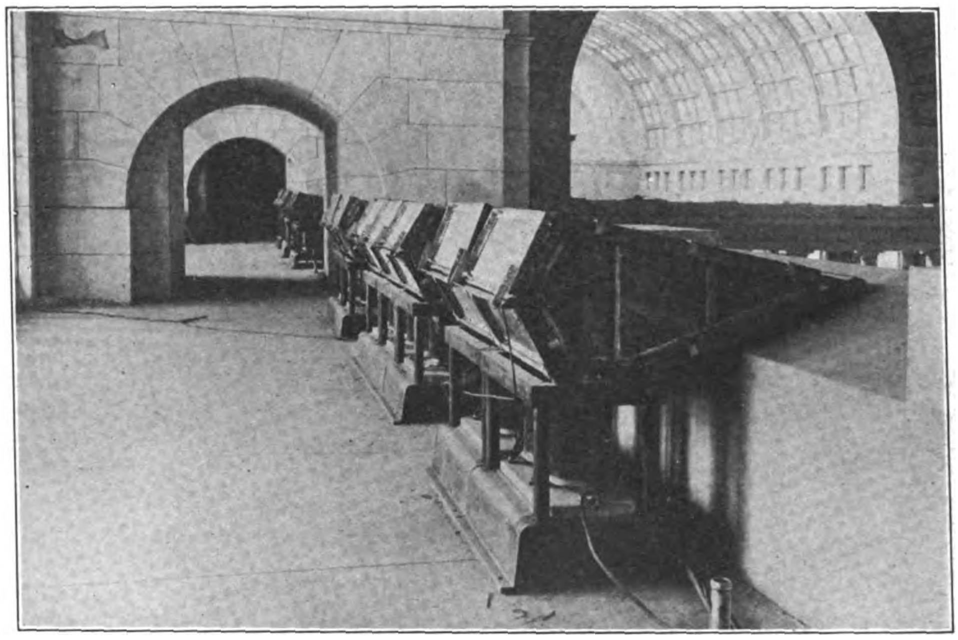
In the preliminary design of the main waiting room it was decided to use some system of lighting by which the fixtures and lamps would be concealed. The room covers a floor space of 120 feet wide by 230 feet long, and has a barrel-shaped ceiling of sixty feet radius, the highest point of which is about ninety-eight feet from the floor. A series of five alcoves which form galleries over the entrance vestibules, run along the sides of the room, with colonnades connecting the galleries across the ends of the room. The ceiling is light in color and is decorated with gold leaf. While not elaborate, the decorations are rich and in complete harmony with the fixtures and architecture.

Banks of especially constructed inverted series arc lamps are placed in the alcoves and back of the balustrade on top of the colonnades, with corrugated mirror reflectors behind them to throw the light to the ceiling whence it is reflected to the floor. As an aid to the reflectors, magnetic coils, which tend to draw the arc toward the waiting room, are installed on the lamps and give good results. To soften the light and reduce the bluish-white tint characteristic of arc lamps, "Cathedral Glass" screens of a very light yellow tint are placed over the lamps and reflectors.

The lighting equipment consists of a total of 162 lamps so arranged that several combinations in the number of lamps in service may be had. A series of luxometer readings were taken with all possible combinations of lamps. From the results of these tests it was found: That the corrugated reflectors and light-colored ceiling give almost perfect diffusion; that with all lights burning, at reading distance from the floor, about forty-two inches, the illumination is practically uniform, the curves both north and south, and east and west being nearly a straight line, and the values varying from 2.5 foot-candles in the corners of the room to 2.3 foot-candles in the centre thus making the use of auxiliary lighting on the seats for reading purposes not only unnecessary but out of harmony in color and arrangement with the general scheme employed. The light is a very close approach to daylight and gives practically true color values in every part of the spectrum. Considerable difficulty was experienced in procuring the glass used to soften the color of the light, as it is required that the glass should not absorb too much of one or all colors. By the use of the "Cathedral Glass" and clear inner globes a loss of but sixteen per cent in the light was entailed, that being less than with an opal inner globe alone.

TICKET LOBBY.

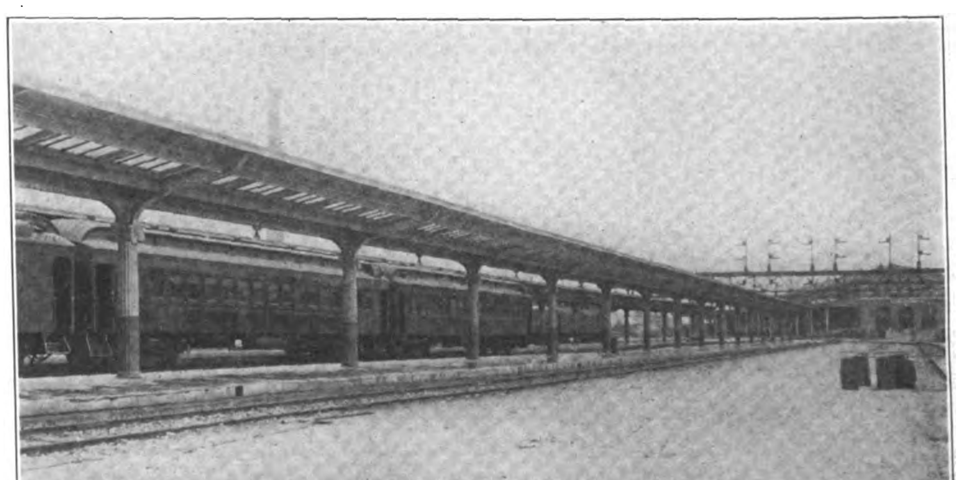
The ticket lobby, located at the west end of the waiting room, is approximately 100 feet long by fifty feet wide with a barrel-shaped skylight ceiling for natural lighting in the daytime. At first the use of a system of lighting similar to that in the waiting room, but with smaller units, was considered. A study of the conditions and tests of the glass indicated that it would be less expensive both in construction and maintenance to install individual lamps above each skylight. Tungsten lamps of 100-watt size with metal reflectors painted inside with aluminum paint are used. The lamps are arranged on four three-wire circuits, controlled by single-pole switches, so that half the lights may be cut out of service without disarranging the symmetry of the lighted panels. The illumination in this portion of the station averages about 2.3 foot-candles, the quality of the light closely approximating that in the adjoining main waiting room and the distribution being equally as good. The reflectors used are of a special design and are so mounted as to direct the light toward the centre axis of the arch. There are in all 225 lamps above the skylight, all being in a pendent position. A very small percentage of the light passes up, the major portion being directed down into the lobby below.



REAR VIEW OF REFLECTOR-FRAMES IN ALCOVE, UNION STATION, WASHINGTON, D. C.

BAGGAGE ROOM.

The baggage room on the first floor is lighted during the daytime by seventeen saw-tooth skylights through a ceiling of maze glass panels. For artificial illumination one arc lamp is placed above each ceiling panel with good results. Each lamp is equipped with a large reflector. The skylight tile-work has also been painted white with most pleasing results. The effect has been to destroy shadows and color rings, to smooth out and enlarge the distribution of the light, to make the color more mellow and in harmony with

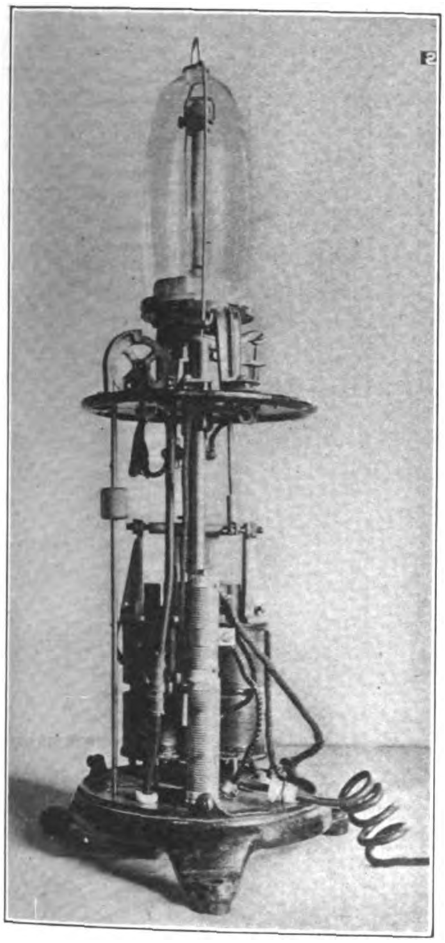


TRAIN SHED LIGHTING, UNION STATION, WASHINGTON, D. C.

that in the adjoining ticket lobby, to direct all the light downward and to reduce the annoying effects of flickering, arc traveling and feeding. The illumination in this room averages about 1.8 foot-candles and is both comfortable and sufficient for the work performed.

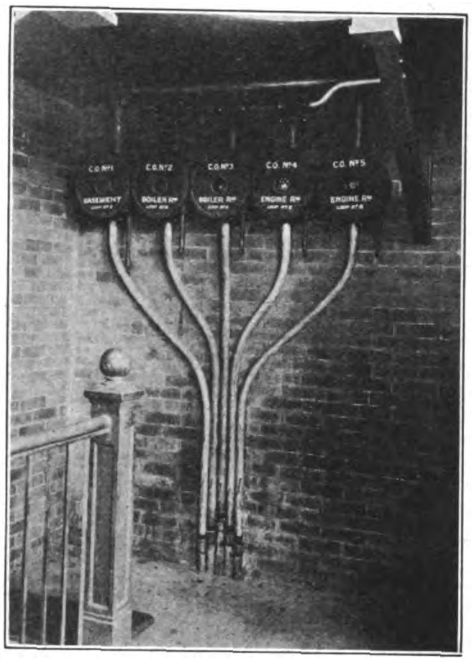
CONCOURSE.

The concourse occupies a space 755 feet long by 150 feet wide between the station building and train shed. It serves as a means of passage to and from trains and



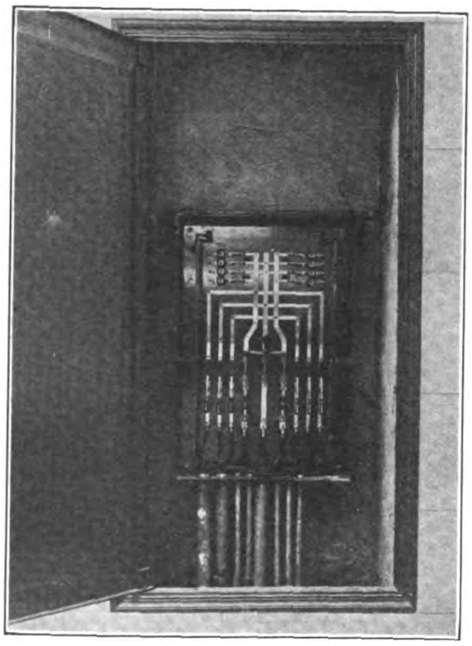
INVERTED ARC LAMP, CASING REMOVED.

is lighted entirely by arc lamps suspended about seven feet from the ceiling. At this distance from the ceiling the lamps cast very slight shadows overhead. The absence of pronounced shadows is desirable on account of the paneling in the ceiling. It was attempted experimentally to light this space by placing arc lamps between the roof and ceiling over the skylights. The scheme was condemned principally on account of the steelwork supporting the roof casting very pronounced shadows on the skylights and because the glass used has a very large absorption factor and is not uniform in color when lighted artificially. Series direct-current arcs did not give good results on account of the great loss due to absorption. Flaming arcs, by reason of their great quantity of light, gave good results but were abandoned because of their pronounced yellow color being out of harmony with the general color values in other parts of the station and the high



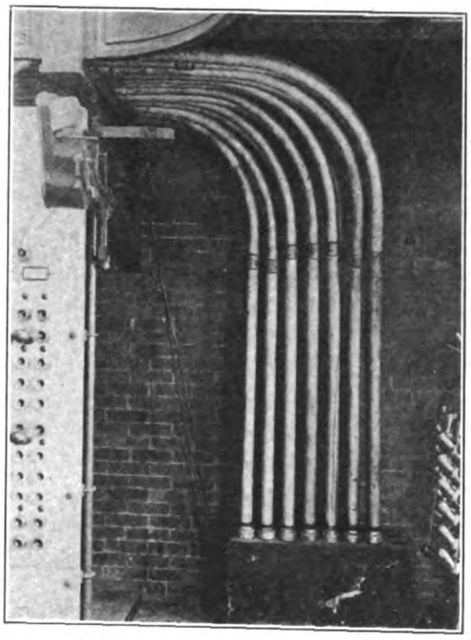
ARC CUTOUTS WITH CONDUIT CONNECTIONS.

cost and difficulty of maintenance in the positions they occupied. Other experiments were also made in an effort to reduce the total number of units used, by employing large diffusers containing four and five units each. This, however, gave the effect of large units of high intrinsic brilliancy and was for that reason aban-



TYPICAL DISTRIBUTING PANEL AND CABINET.

doned. It also produced objectionable streaks and shadows on the ceiling. This system would undoubtedly have worked out well had the ceiling been designed so as to have the diffusers set in it instead of below it. The reasons for abandoning this system were due to the original layout not conforming to its use and not to any faults in the diffusers themselves. With the diffuser installation the illumination on the floor was sufficient, pleasant and well diffused, the streaks and shadows on the walls and ceiling being due to the nonconformity of the building design and the necessary method of installation. Each lamp is equipped with a clear inner and opal outer globe and the quality and distribution of the light is as good as could be desired. Means have been provided for a suitable casing to cover the wires and insulator directly above the lamp and a canopy to improve the appearance at the ceiling outlet. A collapsible and movable extension ladder is used in trimming these lamps.



CONDUIT IN POWER-HOUSE.

MISCELLANEOUS.

The dining and lunch rooms, women's room, smoking room, state apartments and porticos are lighted from a series of ornamental bronze fixtures. These fixtures show excellent workmanship, and are in strict conformity with the decorations and architectural features of the rooms in which they are placed. The ever-present glare of exposed fixtures, however, is present and the irregularity of illumination is quite pronounced, illumination curves showing a variation in the dining room of from 2.1 foot-candles under the fixture to 0.7 foot-candles along the wall.

Some special lighting, in the form of incandescent lamps with reflectors placed in coves formed in the cornices, is installed in the main entrance to the state apartments and also in the vestibules. This system gives a very satisfactory effect but the installation is too small to be of much value in gathering technical data. The ticket cases and counters, show cases in the drug store, news stand and flower booth are lighted by Frink reflectors, the lights being concealed as much as possible.

The lighting of the offices is uniform in design. One and three-light fixtures finished in dull black are used. The sockets are arranged for vertically suspended lamps, permitting the use of Tungsten lamps at some future date, and for Holophane shades. Each office is equipped with two or more ceiling fixtures, depending upon the size and shape of the room, and floor and baseboard outlets are installed at convenient locations. All ceiling fixtures are controlled by flush pushes mounted on wood mats on the walls. Hallways are lighted by Gem lamps varying from fifty to 125 watts and are encased in eight, ten and twelve-inch globes, according to size. The kitchen apartments are lighted and ventilated to some extent by combined fixtures and fans.

The train platforms are covered by umbrella sheds supported on cast-iron columns spaced thirty feet apart along the centre line of the platform. One hundred and eighty-seven-watt Gem lamps, equipped with Holophane bowl reflectors, are suspended midway between the columns from especially designed outlet boxes attached to the steelwork of the roof. These give

POWER REQUIREMENTS SOUTH OF M STREET.

	Total watts.
Small motors at station	225,000
Train tunnel fans	250,000
Battery charging motor generator	50,000

SUMMARY.

Total connected lighting load south of M street	757.5 kilowatts
Total connected power load south of M street	645.0 kilowatts
Total	1,402.5 kilowatts

system has been installed, the master clock being wound automatically by a small alternating-current motor. A telautograph system has been installed for the use of employés only, its principal service being to announce to the employés of the baggage room and station and the express companies the time and incoming track number of arriving trains.

The lighting of the signal towers is special to a considerable extent, it being very desirable to have the operating rooms as dark as possible so as to permit the operators to observe readily the movement of trains. All of the track and signal indicators and the lever machines are illuminated by fifty-watt Gem lamps in connection with special Frink reflectors, no other lights being used in the operating room.

EXPRESS BUILDING.

The express building is a three-story brick building somewhat more than 300 feet long by sixty feet wide. The basement or street floor and first or train floors are used exclusively for the handling of express, while the second floor is used for office purposes. The basement and basement driveway, first floor and train shelters are lighted almost entirely by arc lamps, the lamps being controlled by some twelve or fifteen cutouts. The arrangement of the second floor permits the use of a uniform and symmetrical arrangement of lights. One-light ceiling fixtures equipped with Holophane shades and 125-watt Gem lamps are used throughout, the fixtures being placed at the centre lines of windows. This lighting especially has given general satisfaction.

POWER-HOUSE.

The larger floor spaces in the power-house are lighted by arc lamps, while the smaller machinery passage ways and offices are lighted by Gem lamps equipped with Holophane reflectors. The fixtures as a rule are made of one-half-inch conduit instead of three-eighths-inch and without ornamental tubing on the outside. This arrangement gives a very strong and serviceable fixture. A multiplicity of extension-plug outlets is provided, extension cords equipped with Frink lamp guards and Fullman plugs being supplied.

The terminal is equipped with a private telephone exchange connected with the local, long-distance and railroad exchanges. Postal, Western Union and railroad telegraph service also enters the terminal.

With the exception of the ornamental bronze fixtures which were designed and purchased by the architects, D. H. Burnham & Company, of Chicago, Ill., all of the electrical work on the Terminal company's property south of M street was designed by and constructed under the direction of the motive power department of the Pennsylvania Railroad.

All the electrical work above described was installed by A. S. Schulman, of Cincinnati, Ohio. Credit is due I. R. Prentiss, of the General Electric Company, for many valuable suggestions in connection with the lighting of the waiting room and other important portions of the station. W. D'A. Ryan, of the illuminating department of the same company, also gave valuable assistance in this direction.

The tabulation on the opposite page gives an itemized statement of the kinds of lamps used, method of lighting and wattage per square foot for floor space throughout the buildings described in this article.

Coal Production in 1907.

Advance sheets from the United States Geological Survey, George Otis Smith, director, have been prepared by Beatrice D. Wood, bearing on the production of coal in 1907.

In the production of both anthracite and bituminous coal, Pennsylvania in 1907 exceeded any previous annual record, as reported by the United States Geological Survey in an advance chapter of Mineral Resources of the United States, calendar year 1907, on the production of coal, prepared by E. W. Parker.

The total production was 235,925,749 short tons, having a spot value of $319,421,826. The production of anthracite was 76,432,421 long tons (equivalent to 85,604,312 short tons), having a spot value of $163,584,056. The production of bituminous coal was 150,321,437 short tons, having a spot value of $155,837,770.

Compared with the aggregate production of 1906, which amounted to 200,575,617 short tons, valued at $262,208,345, the output in 1907 exhibits an increase of 35,350,132 short tons, or 17.6 per cent, in quantity, and of $57,213,481, or 21.8 per cent, in value. The increase in the production of anthracite coal was 12,787,412 long tons (equivalent to 14,321,901 short tons), or 20.1 per cent, in quantity, and $31,666,362, or twenty-four per cent, in value. In the production of bituminous coal the increase was 21,028,231 short tons, or 16.26 per cent, in quantity, and $25,547,119, or 19.61 per cent in value.

Mr. M. R. Campbell, of the United States Geological Survey, estimates the amount of coal originally in the anthracite fields of Pennsylvania at 21,000,000,000 short tons and that in the bituminous fields at 112,574,000,000 short tons.

The total production of coal in Illinois in 1907 was 51,317,146 short tons, having a spot value of $54,687,382, the largest production and value yet recorded for the state, an increase of 9,837,042 short tons, or 23.72 per cent in quantity, and of $9,924,320, or 22.17 per cent in value, over the production of 1906. By this increase Illinois was again advanced to second place among the coal-producing states, a position it had held from 1883 to 1906, when it was supplanted by West Virginia.

The total production of coal in West Virginia in 1907 was 48,091,583 short tons, having a spot value of $47,846,630.

In 1906 West Virginia displaced Illinois for second place among the coal-producing states, but her triumph over Illinois was of short duration. As a result of the suspension in 1906, ranging from two months to ten weeks at most of the Illinois mines, pending an adjustment of the wage scale, the coal production of Illinois was materially restricted, whereas in West Virginia, where most of the miners are unorganized, operations were carried on practically without interruption, and that state outranked Illinois, with a lead of 1,810,246 short tons. The record for 1907, however, showed that the production of Illinois made a phenomenal increase of 9,837,042 short tons, more than double West Virginia's increase of 4,801,233 short tons, and West Virginia again dropped to third place among the coal-producing states. Compared with that of 1906, West Virginia's coal production in 1907 showed an increase of 4,801,233 short tons, or 11.09 per cent in quantity, and of $6,794,691, or 16.55 per cent in value.

During the first nine months of the year business was exceptionally active, and the demand for coal was considerably in excess of the supply of cars to transport it, but as West Virginia is one of the producers of high-grade steaming and coking coals, the influence of the monetary disturbance of October was keenly felt. Coke making fell off quickly as soon as the panic began, and the coal production of the state during the last ten weeks of the year was probably not more than fifty per cent of the capacity. Had the production kept up for the entire year at the rate exhibited during the first nine months the total production would probably have reached 53,000,000 tons.

Although a good part of the market for Washington coal in California has been lost through the increased production of fuel oil in that state, Washington shared in the general increase in the production of coal in 1907. The total output for the year was 3,680,532 short tons, having a spot value of $7,679,801, an increase of 404,348 short tons, or 12.34 per cent in quantity, and of $1,771,367, or 29.98 per cent in value, compared with 1906. The average price per ton advanced from $1.80 in 1906 to $2.09 in 1907.

During the first ten months of the year the coal-mining industry of the state was in a highly satisfactory condition. In November and December, however, owing to the financial disturbances, the output of the mines was curtailed about thirty-three per cent. But for this the production would probably have exceeded 4,000,000 tons.

SOME ENGINEERING FEATURES OF THE SOUTHERN POWER COMPANY'S SYSTEM.[1]

BY J. W. FRASER.

(Concluded.)

Substations—The first motor installations in cotton mills on this system were of 550 volts, but it was soon seen that the number of small transformer substations, besides complicating operation, would cost excessively, and after some investigation 2,000-volt motors were recommended for all mills converting from steam to electric drive. These installations proved so successful that to-day over one-half the total horse-power in motors is at 2,000 volts. The cost of the conduit in the mills for 2,000 volts is nearly offset by the smaller wire used and this electromotive force permits all mills within a radius of two miles to be fed from one substation. Many new mills, on account of using individual drive and consequently motors below thirty horse-power, are compelled to step-down at least a part of this current to 550 volts.

The sizes of transformers in substations are as follows:

11,000 Volts. (All purchased before beginning of new development.)					44,000 Volts.				
5	Stations with	3	100	kw.	1	Stations with	2	100	kw.
5	" "	3	125	"	1	" "	3	125	"
3	" "	3	150	"	1	" "	3	150	"
1	" "	3	200	"	7	" "	3	200	"
1	" "	3	250	"	8	" "	3	300	"
1	" "	3	500	"	5	" "	3	500	"
					1	" "	3	750	"
					4	" "	3	1,000	"
			7,575 kw.					34,175 kw.	

Many of the 44,000-volt substations below 900 kilowatts are now partially or wholly owned by customers, as are also some of the 900-kilowatt and 1,500-kilowatt stations, most of the mills in one town preferring to take shares rather than pay the additional price for power necessary when the station is owned by the power company. The customer usually requests that the power company buy and install the substation apparatus. The customer gets the benefit of any experience which the power company may have and obtains substations at a minimum cost. In the larger towns where attendants must be kept it has been found more satisfactory for the company to own the substation. The power company has discountenanced the buying of transformers below 200 kilowatts on account of the high cost of completed stations per kilowatt. In the case of a 900-kilowatt station (three 300-kilowatt transformers) when the transformer cost is two-thirds of the total and 150 kilowatts cost fifty per cent more per kilowatt than 300-kilowatt transformers, the power company has taken a share in the station rather than have the customer install the small transformers. The companies consider this to be to their interest in view of the facts that they get all new mills and that the interest on the additional investment for two years would not pay the installation charges for substituting the large transformers when they were needed.

All substation transformers have been purchased under a standard specification in order that a few stock transformers which the power company has made it a policy always to keep on hand, may serve as spare apparatus in case of accident.

It is believed that no transformers below 300 kilowatts and very few below

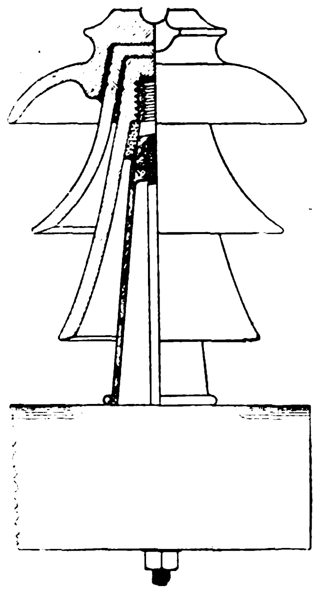

Fig. 6.—44,000-Volt Insulator.

500 kilowatts will have to be purchased in the future, for with the present rapid growth of cotton mills and the use of 2,200-volt distribution in the towns where substations are located, the small transformers will have to be exchanged for larger ones, the smaller ones being available for the new substations carrying small loads.

It may be of interest to some to know that there are now on our lines 114 50,000-volt fuses of the expulsion type and that they have proved entirely satisfactory.

Secondary Power—From government records and from six years of gaugings before the completion of the Catawba plant, together with two years' operating experience, the flow of the Catawba River had been pretty well determined. The question which presented itself most forcibly was whether to develop the average minimum twelve months' flow, or to develop for ten months, eight months or less, and to supplement with steam power; a problem which has to be determined by the first cost of development and by local market conditions.

Owing to limited library facilities at his command the writer was unable to ascertain if this question had been touched upon elsewhere and how in other cases it had been determined, and so trusts that a few words with reference to this particular case will not be amiss.

In following calculations where the cost of primary and secondary power is taken at a fixed rate, the intention is not to convey the idea that these are actual figures but relative figures which will serve the purpose of this paper.

There are many different solutions to the problem of ascertaining the amount of secondary power which may be economically developed. At one of our developments it was found that the average minimum primary power was in the neighborhood of 16,000 kilowatts and that the increase per month of secondary power was in the neighborhood of twelve and one-half per cent; *i. e.*, 2,000 kilowatts per month. In other words, if secondary power was to be developed for eight months' sale the total development of primary and secondary power would be 24,000 kilowatts. If this secondary power can be sold without an auxiliary steam plant the amount of secondary power which may be developed economically depends only upon whether or not the price received for such power will cover interest and profit on the investment; that is, the investment which is over and above that for developing primary power, but if a steam plant has to be maintained the amount of secondary power to be developed depends also on the cost of steam power. It is very clear that the cost of secondary power is practically the same whether it is sold for eleven months or one month. With this cost, say at $10 per horse-power delivered, steam at $28 per horse-power-year ($6 interest and depreciation, $22 for coal, operating expenses, etc.), if interest and depreciation on the steam plant is entirely chargeable to the months when steam plant is in operation, then

Cost of steam power per month $= 1.83 + 6/x$

When $x =$ the number of months in operation.

Amount of secondary power to be developed $= 16{,}000$ kilowatts $\times\ 12.5x/100 = 2{,}000x$

Cost of steam-secondary

$$= 2{,}000x\ (1.83 + 6/x)\ x + 2{,}000x \times 10$$
$$= 2{,}000\ \ (1.83x^2 + 6x + 10x)$$

[1] A paper presented at the annual convention of the American Institute of Electrical Engineers, Atlantic City, N. J., June 30. For a description of the different power sites owned by the Southern Power Company see Electrical Review, September 8, 1906, p 367.

If power is selling at $20, profit

$$= (2{,}000x\ 20 - \{2{,}000\ (1.83x^2 + 16x)\}$$
$$= 2{,}000\ (20x - 1.83x^2 - 16x)$$
$$(\text{For max.})\ dy/dx = 3.66x - 4$$
$$x = 1.1 \text{ month}$$

On this basis maximum profit would be made on 2,200 kilowatts secondary development.

A more practical method under existing conditions seems to be to charge the interest and depreciation of steam plant to the operating expenses of the system, inasmuch as the steam plant is an insurance

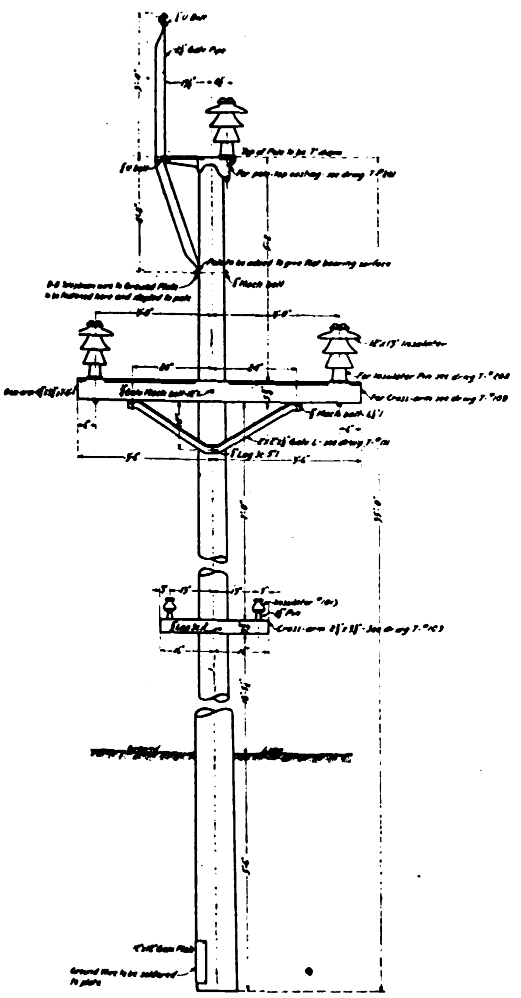

Fig. 7.—Standard Wood Pole.

against a partial shut-down and makes spare units unnecessary, and in the case of steam turbines, when run as synchronous motors, saves copper because it brings up the power-factor. The above equation now becomes:

Cost of steam + secondary

$$= 2{,}000x\ (1.83x) + 2{,}000x \times 10)$$
$$= 2{,}000\ (1.83x^2 + 10x)$$

Profit

$$= 2{,}000 \text{ X } 20 - (2{,}000\ (1.83x^2 + 10x)$$
$$= 2{,}000\ (20x - 1.83x - 10x)$$
$$= 2{,}000\ (10x - 1.83x^2)$$
$$(\text{For Max.})\ dy/dx = 3.66x - 10$$
$$x = 2 - 3/4$$

Maximum profit on this basis would be made on 5,500 kilowatts (35 per cent) secondary development.

Had $24.50 been taken as the selling price of power x would equal four months, or the total development should be made for 150 per cent of mean average low water. Although power from hydroelectric plants has been selling in the Carolinas for less than this latter figure there is no doubt that reliable service demands this price.

There is another argument in favor of developing for 150 per cent mean average low water. If it costs only one-half as much to develop secondary power as primary, twice the loss can be allowed on transmission lines; or, in other words, one and one-half times the power can be transmitted during secondary power seasons. Now, if the transmission lines are figured for an economical loss when transmitting primary power only, secondary power to the extent of fifty per cent of the primary power can be developed without additional copper. This only holds good when the auxiliary steam plants can be built in the neighborhood of distribution centres whose consumption of power is equal to the amount of secondary power.

Many mills which had steam plants already installed made contracts for secondary power for eight months in the year, but after a few months' operation by electric drive their owners found the production so much increased and their labor and other troubles so much lessened that many of them desired to change their contracts to primary power. The result of this is that the plans for a supplementary steam plant are now in course of preparation. The initial installation will be 15,000 kilowatts and will be located at Spartanburg, S. C., near the southern end of the system, sixty-four miles from the main switching station at Great Falls on the 88,000-volt line. The ultimate installation is expected to reach 40,000 kilowatts, divided between this point and some point near the eastern end of the system. It is thought better to divide the plant for safety and in order that the line loss may be kept as low as possible.

BOOK REVIEW.

"American Street Railway Investments." New York. McGraw Publishing Company. Cloth. 473 + xliv pages. 10 by 13¼ inches. Illustrated with maps. Supplied by the Electrical Review for $5.

This is the fifteenth edition of the electric traction "Red Book." It is hardly necessary to say much about this excellent reference book. The data have been brought up to date and several new maps indicating extraordinary developments have been added. There is no other reference of a similar character, and the book, therefore, stands in a class by itself. It should certainly be of considerable interest to those desiring accurate and recent information concerning street railway properties.

Resistance of a Conductor Having a Sudden Change in Size.

At a recent meeting of the Physical Society, of London, a paper entitled "On the Resistance of a Conductor of Uniform Thickness Whose Breadth Suddenly Changes and on the Shape of the Stream-lines" was read by Professor C. H. Lees. A knowledge of the resistance of a conductor whose section suddenly changes is of considerable practical importance, but mathematical difficulties have prevented an exact solution of the problem. Lord Rayleigh had given an approximate solution of the case in which a cylinder of circular section is joined at one end to the plane surface of a large conducting solid; and Professor Hicks has solved the case of a wire of small diameter ending in the surface of a conducting sphere. The mathematical difficulties of the problem disappear if the conductors are of rectangular section and one dimension, *e. g.*, the thickness remains constant while the breadth suddenly changes and the two are joined together either with their axes or with two sides collinear. The paper shows that the resistance between two transverse sections through points situated at considerable distance from the change of section on opposite sides of it is equal to the sum of the resistances of the portions of conductor between each of the two sections and the change of section, each considered as part of an infinite length, plus the resistance of a length of either conductor equal to its breadth multiplied by an expression given.

Dr. Russell congratulated the author on having obtained the exact solution of an important problem and thanked him for giving it in a form in which it could be utilized readily by electricians. Somewhat similar problems were of frequent occurrence in practice, in particular he instanced the measurement of the resistance of the bonds connecting the rails in electric tramway systems. The difficulty in this case was in knowing where the rail ended and the bond began. A small variation in the position of the potential contacts made a large variation in the reading of the galvanometer. In many cases the only way of attacking the problem was to calculate the resistance from the known resistivity of the metals by the approximate method indicated by Maxwell. An exact solution, therefore, like the one obtained by the author, would be of great value in checking the accuracy of the approximate method.

ELECTRICAL MACHINERY IN A GREAT CORN PRODUCTS PLANT.

BY C. A. TUPPER.

One of the most recent of the few great plants devoted to the processing of corn products is the American Maize Products Company, of Roby, Ind. There are not many plants devoted to this industry, owing to their great size and first cost. The corn, before it is available for food or industrial purposes, must pass through a great many operations of weighing, steaming, crushing, grinding, sieving, separating and packaging. In all of these operations the electric drive plays an important part. In this plant, alternating-current motors of the induction type, built by the Allis-Chalmers Company, Milwaukee, Wis., have been used. Most of these are of standard construction, but the motors connected to the buhrstone mills, for grinding the corn very fine, are special machines, having been developed for this purpose. The applications of these motors are well shown in the accompanying illustration. Each is of the vertical belted type designed for operation on sixty cycles, and has a normal rated output of seventy-five horse-power. The stator core is supported in a cast-iron housing provided with projecting lugs that rest on the slide rails. The stator core shows open slots that allow the coils to be readily removed in case repairs are necessary. The stator has a fourteen-pole winding, thus giving a synchronous speed of 514 revolutions per minute, the full-load speed being approximately 490 revolutions per minute.

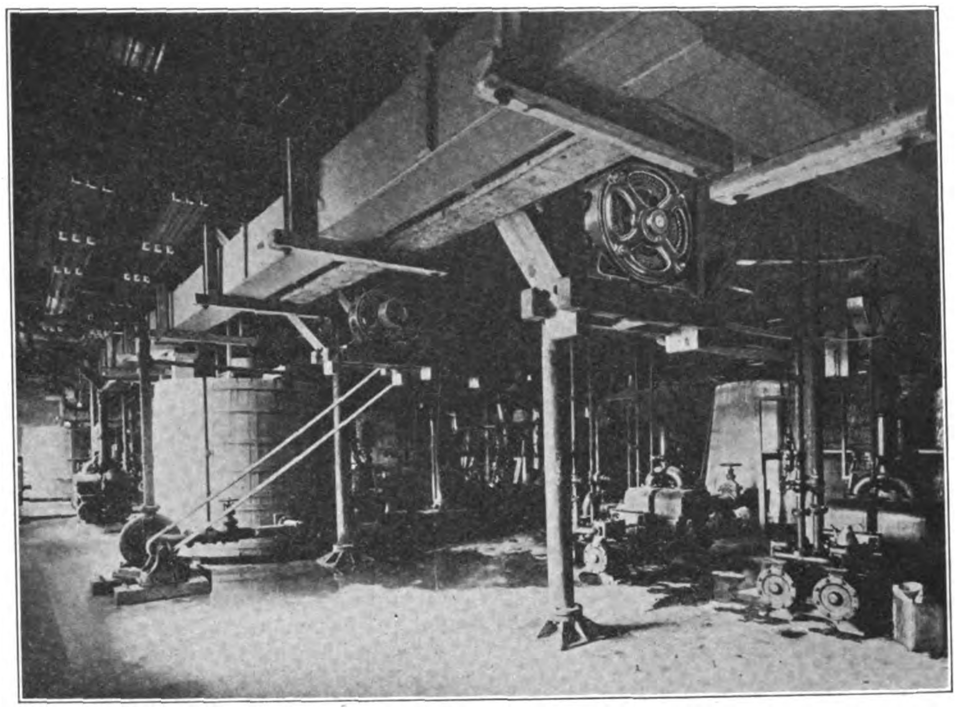
The rotor spider is mounted on a vertical shaft which passes through a guide bearing at the top of the motor. A second guide bearing is placed at the bottom, and the weight of the rotating part is carried by a multiple-disc, self-aligning thrust-bearing under the lower end of the shaft. A complete oiling system is provided whereby oil is supplied to the upper bearing from a large sight-feed oil cup and, after passing through this bearing, flows to the lower one. The thrust-bearing is designed so that all parts are thoroughly lubricated. The pulley is at the top of the motor, and the vertical arrangement allows the motor to be belted directly to the mill without the use of a quarter-turn belt.

In addition to the buhr mills the elevators, conveyers, shaking sieves, and, in fact, all of the moving machinery, are driven by motors of capacities ranging from five to thirty horse-power.

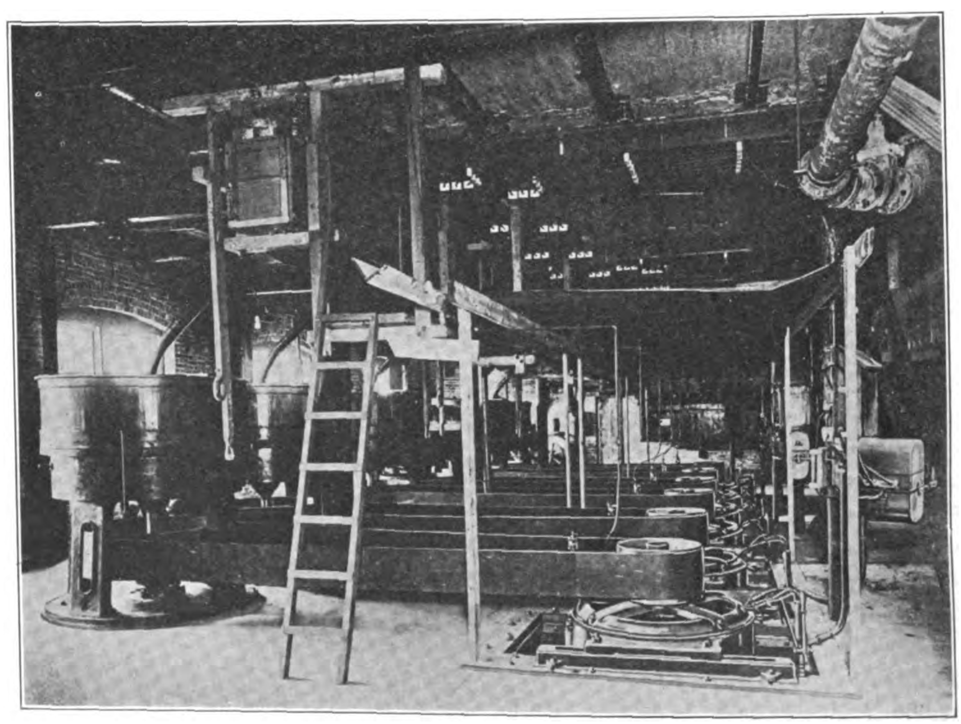
Not the least important part of this great plant is the pumping machinery, which consists of the following units supplied by the Platt Iron Works, Dayton, Ohio:

Two twelve and eighteen by fourteen by eighteen-inch duplex pumping engines of the outside centre-packed plunger type, each having a capacity of 1,400 gallons of water per minute. Three single-stage centrifugal pumps for the steeps, each having a capacity of 200 gallons per minute. These pumps are placed on extended bases and direct connected to seven-and-one-half-horse-power motors. The shaft coming in contact with the liquor is made of bronze composition. One single-stage centrifugal pump for the shakers, having a capacity of 400 gallons per minute. This is direct connected to a fifteen-horse-power motor.

One single-stage centrifugal pump for discharging slop from the buhr mills, having a capacity of 400 gallons per minute. The pump is placed on an extended base and direct connected to a seventeen-and-one-half-horse-power motor. Four



INDUCTION MOTORS FOR DRIVING PUMPS AND SPECIAL MACHINES IN GLUCOSE FACTORY.



SEVENTY-FIVE-HORSE-POWER VERTICAL INDUCTION MOTORS BELTED TO BUHR MILLS IN PLANT OF AMERICAN MAIZE PRODUCTS COMPANY, ROBY, IND.

single-stage centrifugal pumps for crushed corn, each direct connected to a fifteen-horse-power motor. One single-stage centrifugal pump for the starch-breaker, having a capacity of 400 gallons per minute, direct-connected to a fifteen-horse-power motor. One single-stage centrifugal pump for water, having a capacity of 700 gallons per minute, direct-connected to a twenty-two-horse-power motor.

The centrifugal pumps are of the balanced type, with single suction opening. The casing is circular and concentric, fitted with discharge flange, and with feet for bolting to the foundation. The suction is on the drawing side and admits the water to that side of the casing. It passes through cores in the chute case to the front end of the impeller, so that the impeller has suction on each side and is consequently balanced.

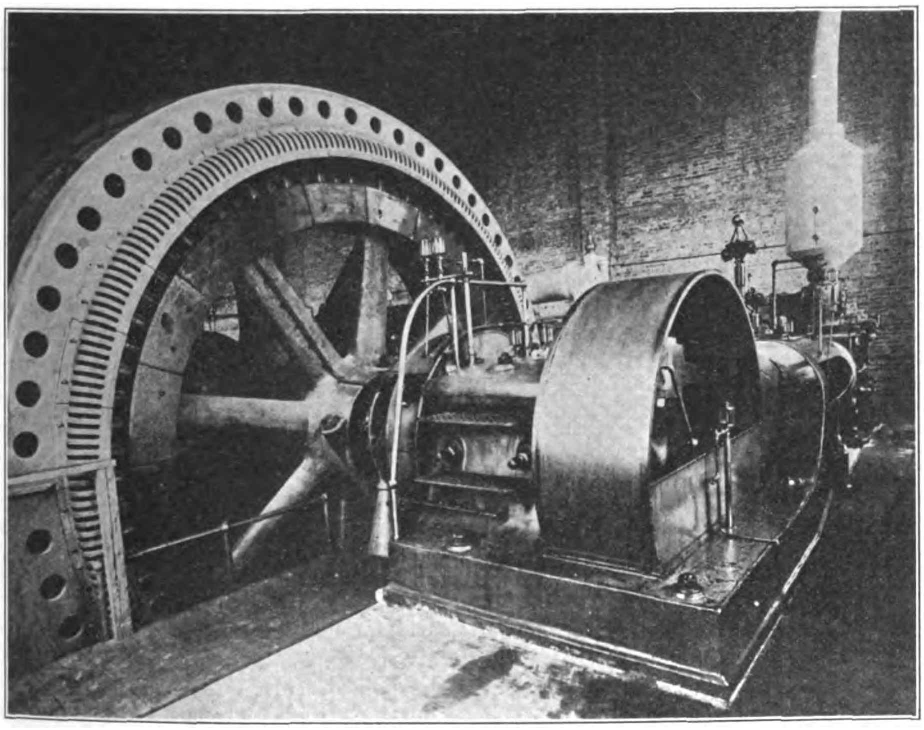
Two eight and eight by ten-inch duplex pumps and two ten and ten by ten-inch duplex pumps, with plain slide-valve steam cylinders and piston-packed water boxes for operating under a liquid pressure of fifty pounds, with an available steam pressure of 130 pounds.

Six eight and six by ten-inch duplex yoke-type pumps for the refinery. Two twelve and eight by twelve-inch duplex outside centre-packed plunger boiler-feed pumps, equipped with chilled-iron plungers, brass-covered plunger rods and brass-bushed plunger glands and boxes.

Two ten and sixteen by ten-inch duplex crank and flywheel vacuum pumps, provided with automatic governors.

One ten and ten by twelve-inch duplex clapper-valve pump, with slide-valve steam end, and brass-fitted clapper-valve liquid end.

The power plant has been designed in strict accordance with latest practice and possesses many features of special merit. In the engine room there is but one large main unit, which is a twenty-six and fourty-four by forty-eight-inch Allis-Chalmers cross-compound Corliss engine, connected to an alternator of the same company's build and having a normal rating of 800 kilowatts. The generator is a three-phase sixty-cycle machine of the revolving-field type and was designed to deliver 480 volts' pressure at a speed of ninety revolutions per minute. The rotor of the generator is about seventeen feet in diameter and weighs seventeen tons. The load carried by this machine is mostly power, consisting of 150 motors and ranging in capacities from five to seventy-five horse-power. There is, of course, a sufficient number of incandescents to light the plant. The lights are carried on three-phase feeders and as nearly as possible are distributed equally between the phases. From four to six hours a day the large unit is run on twenty-five per cent overload and apparently carries it with the greatest of ease.



800-Kilowatt, Engine-Driven Alternator in Plant of American Maize Products Company, Roby, Ind.

Besides the large unit there is a smaller direct-connected set consisting of a fourteen by fourteen-inch Chandler & Taylor engine and a three-phase Allis-Chalmers revolving-field generator. To this set is also belted a thirty-five-kilowatt direct-current exciter. The small set is used only at night or any time when there is a very small load to carry. When starting up the larger unit it is also used for exciting current, the three-phase alternating-current being transformed to direct current by means of a fifty-kilowatt motor-generator set. The belted exciter may also be used, so that there are at least two sources of excitation. When the large machine is running exciting current is obtained from the motor-generator set, the synchronous motor receiving current from the main generating unit.

For control of the electrical apparatus and distribution of the load the station has a seven-panel switchboard, which was installed by Kohler Brothers, of Chicago. The board is equipped with a full line of instruments, consisting of ammeters and voltmeters of Wagner make, Westinghouse integrating and recording wattmeters, a Westinghouse synchroscope and power-factor indicator. Condit three-pole circuit-breakers are installed and Cutler-Hammer chain-operated field rheostats.

In the same room, but at a lower level than the power-plant floor, are some of the pumps previously mentioned, that is, the two pumping engines for water supply, the two boiler-feed pumps and the two Underwriter fire pumps. In addition to the pumps are two Stilwell feed-water heaters, with space for a third, and also an air-compressor to furnish the shop with a supply of compressed air for pneumatic tools, etc.

On account of the large demand for steam throughout the plant there are six Aultman & Taylor boilers installed, each rated at 440 horse-power, set singly and each having 4,403 square feet of heating surface. The boilers carry a pressure of 150 pounds per square inch, and five of them are in constant operation, with one down for cleaning or repairs. They are equipped with chain-grate stokers of the Mansfield type and are run with natural draft supplied by a radial brick stack built by the Heine Chimney Company, of Chicago. The stack is 200 feet high from the boiler-room floor, which is six feet above grade, ten feet in diameter all the way up and has a radial brick lining for sixty feet of its height. It is located right in the boiler room, midway between the two middle boilers, and has a flue opening on either side with a six-inch baffle wall in the middle to prevent interference of draft. For a brick stack the location is unusual and a peculiar feature is the passageways under the stack. These are at right angles to each other and are on a level with the boiler-room floor. A cable is drawn around the top of the chimney and is provided with four points, each having a twelve-inch platinum tip. Two ground connections are provided and the cables are secured to the chimney by means of bronze anchor fastenings.

Special care was taken in the design of the breeching, which was built up of brick and covered with reinforced concrete. As above indicated, there are three boilers on each side of the stack, so that there are three boilers discharging their gases into each breeching. On this account the area at the entrance to the stack was made equal to three times the area of the outlet from the boiler, twice as large between the second and third boilers and at the first boiler of the same size as the outlet. This arrangement gives each boiler an equal draft and prevents any choking of the gases in its passage to the stack.

Feed water for the boilers is taken from Wolf Lake, which is only a few feet from the plant. The water in this small lake is unusually muddy, and it was necessary to install a filtration plant for its purification. The National Filter Company, of Chicago, erected the plant.

For the supply of the entire works the water is drawn from the filtration plant through a twelve-inch pipe by one of the pumping engines previously mentioned. To this main supply a four-inch tap is made for boiler feed, and before reaching the boilers the water is passed through the Stilwell feed-water heaters, which are twelve feet nine inches high and sixty-six inches in diameter. The heaters raise the water to a temperature of 200 degrees Fahrenheit. But little cold water is required, however, as the condensation from traps and exhaust is usually sufficient.

To collect the ashes, each boiler is provided with an ash hopper, from which the ashes are taken in small dump cars. These cars are pulled mechanically outside of the building and the ashes are dumped on the premises and used for filling purposes.

As the coal used in the stokers contains considerable dust after passing through the crushing machine, there is a good deal of fine material which will drop through the chain grates, and in a great many cases is entirely wasted. In the plant under description, however, each hopper is provided with a plate to divert the fine coal dropping through in this manner. Provision is now being made to convey this fine coal to the elevator and eventually return it to the stokers.

Two steam headers have been provided: the main header, which is sixteen inches in diameter, and an auxiliary header, eight inches in diameter. With the piping arrangement it is possible to utilize either header and cut out, if necessary, either half of the main header for repairs. From one to the full number of boilers can be turned onto the headers as desired, and there is no danger of any pumping back and forth between the boilers from unequal pressures, as each leader is equipped with an automatic stop valve.

Live steam is used to some extent in the plant, especially for the fan engines, steam dryers and pumps, in connection with the drying rooms. Most of the steam, however, used for the various processes is exhaust from the engine units and the pumps. For this reason condensers are not installed. This supply of exhaust steam is collected in a large eighteen and twenty-inch pipe, and at infrequent intervals, when the steam is not all required in the plant, it is exhausted to atmosphere.

Of the entire boiler room, the feature of chief interest is undoubtedly the coal-handling apparatus. This is unusually complete for a plant employing only six boilers.

A receiving conveyer has been placed parallel with the track on which the coal arrives, being between the track and the wall of the boiler house. The conveyer is provided with a hinged shoveling apron placed at an angle of about sixty degrees between it and the side of the car. To this apron the coal is shoveled and flows down on the conveyer, and is carried forward and discharged to a standard boiler-house crusher, operated by a thirty-horse-power Allis-Chalmers motor, by which mine-run size is reduced to one-and-one-half-inch maximum cubes.

The hopper that receives the crushed coal is connected by a chute to a continuous bucket elevator, which raises the coal and transfers it to a flight conveyer extending through the boiler house over bunkers. It is then delivered by the conveyer through gates placed in the trough to such bunkers as it may be desired to fill.

When handling mine-run, the capacity of the installation is governed by the maximum capacity of the crusher, which is from forty to fifty tons per hour. When handling fine coal not requiring crushing, the capacity is controlled by the elevator, namely, from fifty to sixty tons per hour. The system is electrically driven throughout with controlling mechanism located inside the boiler house. It was installed by the Link Belt Company, of Chicago.

In an installation of this kind, with the coal hoppers above the boilers and feeding the coal through chutes to the stoker, difficulty is always experienced in opening or closing the gates controlling the supply of coal, as they are very apt to wedge or become stuck in some way. To prevent this and get a straight pull or push on the gate, a bell crank-and-screw arrangement was provided. The screw has only five threads to the inch, so that a few turns of the wheel will open or close the gate.

Another feature of interest is the poke rod. This is provided with a ball which will close the opening through which it passes and at the same time allow a thrust in any direction to start the coal if it happens to become lodged at the mouth of the hopper.

The power-house, corn-storage tanks and manufacturing buildings are of fire-proof construction, and the warehouses are of mill construction. All buildings are so arranged as to have excellent light and ventilation, and the floors of the fire-proof buildings are arranged to be flushed with water at the close of each day, so as to have them at all times in a state of cleanliness and perfect sanitary condition. A complete sprinkler system is installed, and with a 50,000-gallon water tower in connection with the two fire pumps a pressure of 200 pounds is maintained all over the grounds.

This plant, which was planned and constructed under the supervision of its superintendent, P. L. Saenger, assisted by G. C. Welch, S. H. Lanyon and J. J. Waechter, is designed to handle 30,000 bushels of corn daily, the machinery for one-half of which has already been installed. In completeness and economical operation it leaves practically nothing to be desired, and the large demand for corn-starch and syrups now existing throughout the country insures a good market both for its products and those of the company's predecessors in this particular field.

Michigan Telephone Returns.

In its application to the New York Stock Exchange for the listing of additional common stock the Michigan State Telephone Company gives the following statement of income for the four months ended April 30 last: Receipts, $1,084,182; total expenses, $807,936; net earnings, $276,246; interest, $134,433; balance for dividends, $141,813; dividends on preferred stock, $45,664; surplus, $96,149.

THE ADVANTAGES OF MEMBERSHIP IN THE AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

BY CHARLES B. BURLEIGH.

The question has frequently been asked, What advantage is to be derived from membership in the American Institute of Electrical Engineers?

There can be no question as to the duty of every American citizen to support and maintain the Supreme Court of the United States. Can there, therefore, be advanced any legitimate reason as to why it is not a duty that he owes, not only to himself but to each and every one of his associates in the business in which he is engaged, for every electrical engineer to do his utmost to support and maintain a court of last resort, by whom all disputed technical questions in electrical engineering shall be finally settled; to assist so far as in him lies, in removing all electrical work from the region of guesswork to that of certainty, thereby increasing the stimulus to the successful investment of capital in electrical enterprises; to effect a concentration of effort and increased mentality excited by generous rivalry?

With these objects in view the American Institute was formed with the avowed purpose of "promoting the arts and sciences connected with the production and utilization of electricity and the welfare of those employed in these industries; by means of meetings for social intercourse, the reading and discussion of professional papers, and the circulation, by means of publications among its members and associates, of information thus obtained."

Appreciating this situation, affiliation with the organization is not a question of what benefit will result to the individual but is a duty he owes to the art, to his associates and to himself, to do everything in his power to aid and assist in the support and maintenance of an institution without which we would all be whirling around in our own little circle, duplicating effort, narrowing the scope of the art and our own fields of usefulness.

The electrical engineer also owes a duty to the public in general, who place in his hands the solving of problems in connection with the details of which they are totally uninformed, and only by placing himself in a position to give them the best information procurable can he be assured of rendering to them full return for the confidence imposed. Again, it is generally conceded by the world at large that the most valuable opinion and judgment on any class of work is that rendered by the leaders in that profession; for which reason the electrical engineer's standing is in a great measure fixed by the recognition of his ability by his associates, and only by an acquaintance with them, thus offering them the opportunity to familiarize themselves with his capabilities, can he establish his standing, and as the best estimate of an engineer as a man and an engineer is the opinion of the members of his own profession, it is his duty to himself, as well as to those from whom he derives his livelihood, that he become known to and acquainted with his associates.

Association with the leading organization connected with the business, composed of men who are recognized by their associates as masters of their profession, offers the most available opportunity for this acquaintance and as rubbing against the smutted kettle will besmirch, so will close contact with the bright tend toward polish mentally as well as physically.

The benefits to be derived from this association depend largely upon the individual to the extent that if he joins the organization, prompted only by selfish motives, to receive and not to impart benefit, he will receive but little, while he who connects himself with the association, hoping by his work to promote its success, receives in return inestimable benefit from the fact that his work and his contributions tend to make him known to his associates and establish his standing not only among them but in the field at large.

Again, in connection with the different matters brought before the organization for its consideration, he either attends the meeting at which they are presented or reads of them in the transactions, and as reading any similar article presented through the usual channels, forms his own opinions on the subjects treated, but his connection with this association offers him the opportunity to familiarize himself with the opinions of his associates on the subject, and by discussing their opinions, either with them or with himself, arrives at a much broader understanding of the matter.

As the association aims to take up and discuss in its earlier stages of development any and all improvements in the art, the facilities offered enable the membership to keep just a little ahead of the non-members and the public, and prepares them to pass judgment on new devices as soon as their practical consideration becomes desirable.

The scope of the art is continually broadening to such an extent that the necessity for specialization is becoming more and more apparent. The closer the lines are drawn in this direction the more important becomes an organization which offers us the facilities for keeping in touch with the whole general situation, and the more good work can the specialist do for the organization and through it for the art.

Having been connected with the electrical business for some thirty years and with the Institute seventeen years, I feel that I may be pardoned for a suggestion to the older members and a word of advice to the younger members of the profession.

To the older members I would say:

You have seen our profession grow in the last thirty years from the electrician who could set up and connect the gravity cell for the operation of the key and sounder to the electrical engineer who can carry on his shoulders the water and steam power of the world and deliver its useful energy at any point where commercial conditions make its utilization desirable, outstripping by leaps and bounds all other engineering professions.

I may have contributed individually no more than you to this marvelous development, but the association of which I am a member is in a great measure responsible for it, for which reason you owe to it in a large measure the benefit you have and are receiving from it. You would be ashamed to be accused of not paying your just debts. Here is one long overdue, and the quicker you settle by adding your assistance to the good work in becoming a member the sooner you can look everybody in the face and say, "I am in part responsible for the results attained."

To the neophyte I would say:

In any line, individual effort is always praiseworthy, but team work presents the shortest route to success.

The sooner you connect yourself with the Institute the quicker you will begin to obtain the best returns from the energy you expend in promoting the interests of the profession you have entered, to the benefit of your employer and to yourself, and if you remain in the business you can look back with pride, in the years to come, to the fact that you have always, from the first moment of entering the profession, lent your best efforts to the best advantage to the advancement of the art.

You may feel that you have completed your education and are now about to reap the benefits. Allow me to disabuse your mind of this idea. Your education has just commenced. Your school and college have provided you with an excellent outfit of tools and you are now about to be taught how to use them to the best advantage.

The art is progressing and you will find that new adaptations require new tools not in your chest and membership in the Institute will tend to keep your tool chest up to date.

REVIEWS OF CURRENT ENGINEERING AND SCIENTIFIC LITERATURE

The Spectrum of Radium Emanation.

Having secured a preparation containing about 250 milligrammes of radium, E. Rutherford and T. Royds seized the opportunity thus offered to study the spectrum of the emanation given off by this preparation. It was found that the minimum volume of the emanation per gramme of radium was not in accordance with that to be expected from calculation. This emanation was condensed by liquid air in an exhausted tube of about fifty cubic millimetres capacity, provided with thin platinum electrodes. Two photographs were taken immediately, one of which shows about thirty intense lines and the second more than one hundred lines. The color of the discharge in the tube was bluish. Visible observation was also made. When the emanation was condensed in a side tube by means of liquid air the character of the emanation of the lines vanished. The color of the discharge changed completely and became a pale rose. At the instant of volatilization the emanation lines flashed out again. The hydrogen lines were visible in the spectrum and became more brilliant when the emanation was condensed. These lines were not observed in previous experiments where an electrodeless discharge took place and they were probably due to hydrogen given off by the platinum electrodes. It was noticed that the amount of pure emanation in the tube gradually diminished with the increase of the time of the discharge. The spectrum, however, persisted until all of the emanation had been driven into the walls of the tube. The wave-lengths of the lines of the plate were accurately measured, the results agreed fairly well with the determination made by Ramsey and Collie in 1904. —*Abstracted from Nature (London), July* 9.

Apparatus for Checking the Adjustment of Automatic Oil-Break Switches.

It is very desirable that some means should be provided for enabling the adjustment of automatic oil-break switches to be checked quickly from time to time. These switches are operated automatically by means of trip-coils which are excited from a source of continuous current or alternating current. When direct-current tripping-coils are used it is an easy matter to test them to see if they are in order. In fact, it is common practice to arrange a push button for the contacts of the controlling relay, thus exciting the trip-coil and operating the switches. But when alternating-current trip-coils are used it is not so easy to test them. Such coils are fed very often directly from the secondary of a current transformer without an intermediary controlling relay. There is not sufficient current to operate the relay passing through the trip-coil until there is an overload. Under ordinary circumstances it is not possible, without making special arrangements, to get sufficient current through the trip-coil to cause it to operate. A means of doing this has been devised by C. C. Gerrard. For this purpose an adjustable choke-coil is used. It may be fed from a source of low-tension alternating current of, say, 200 volts. By means of an adjustable core a secondary current may be obtained within fairly wide limits. The apparatus is used as follows: about once a month the current transformer is short-circuited and disconnected from the trip-coil. The latter is then connected by means of a core through the choke-coil to a low-tension circuit. By varying the adjustment of the core it is easy to determine the current required to open the switches.—*Abstracted from Electrical Engineering (London), July* 3.

The Oscillatory Character of Lightning.

A brief review is given here of a paper read recently by Dr. Bernbach before the German Technical Association, in which the author discusses the character of lightning. He argued, on the whole, against the oscillatory character of lightning discharges. Theoretically a discharge should be oscillatory when the resistance term of the impedance is less than the reactance term. As the resistance of air is very great and the capacity is likewise great, while the self-induction is probably small, it is hardly probable that the second term of the impedance should become larger than the first; the value will, therefore, remain positive and oscillatory discharges should not be expected. Dr. Bernbach contended that photographs of lightning flashes do not show any such oscillations. Such photographs sometimes show a number of successive discharge pulses, following about the same path. The second flash path being longer than the first. The ramifications of a light discharge do not mark any change of polarity and when photographs show bright spots, it is probable that these portions of the discharge appear brighter because the direction of this part of the path is more or less toward the camera. The well-known Leyden jar experiments of Lodge illustrating the peculiar, apparently capricious, deviations of the spark from its natural path do not necessarily demonstrate any oscillations in the currents. The resistance effect of conductors must be taken into consideration not only with high-frequency currents, but with very intense direct-current discharges at a very rapid rate. Although the inductance may be small the rate of change of current may be large and there is trustworthy evidence of lightning currents of more than 20,000 amperes, the time limit being about one minute.—*Abstracted from Engineering (London), July* 10.

A New Development in Cross-section Paper.

A method of using cross-section paper is described here by Henry Hess, which enables the user to deduce easily the equations for any curves of the first or second degree. Two kinds of paper are used, that usually called cross-section, or more properly co-ordinate paper, in which the divisions are uniformly spaced and that in which the ruling follows a logarithmic scale. The first kind is suitable for curves of the first degree. The usual scales, running, say, from one to ten and starting at the lower left-hand corner, are marked off and in addition two other scales are added, in this case running from zero to one, in tenths and starting at the lower right-hand corner for the scale of ordinates and at the upper right-hand corner for the scale of abscissas. The usual scales are employed when plotting the curves. The additional scales are used for finding the constants and exponents of the variables. The method consists in plotting a secondary curve parallel to the primary curve, or making the same angle with the axes, and passing through the origin. The secondary line gives the value of y in the equation $a = yb \pm z$. While the value z is given by the distance of the intercept of the curve from the axis of ordinates, the slope of the curve determines the signs of the different terms. The method of employing the logarithmic paper is the same, except that this is used when the curve is not of the first degree. The general equation being $a = yb^n + z$. The advantage of the logarithmic paper is that the equations then may give straight lines and the intercept of these lines with the new scale at the top or right gives at once the exponent of the second term of the equation. When a constant term enters into the equation the curve plotted on logarithmic paper is no longer a straight line, but a secondary curve of the former, which will be a straight line, is easily plotted. The author shows how the equations most encountered in engineering work are easily deduced without it being necessary to apply the tedious algebraic process.—*Abstracted from the Proceedings of the Engineers' Club of Philadelphia, Philadelphia, April.*

Flywheels or Storage Batteries for Equalizing Fluctuating Loads.

Flywheel storage systems have recently been coming extensively into use for taking up fluctuations of loads, especially in connection with mining work. This arrangement is thought by G. C. Allingham to be best adapted to equalizing the power demand of an individual machine which goes through a definite cycle of operations —which is repeated so that very short periods of heavy and light loads recur alternately in regular succession. In such cases the actual amount of energy that is to be stored is small, although the power to be dealt with is large and this energy must be stored for but a short time. For such arrangements it is possible to work the flywheel equalizer at a comparatively low factor. On the other hand, where the loads are irregular in frequency and amount, and where they last for longer periods or occur in rapid succession and may also be separated at times by comparatively long periods of light load, the flywheel equalizer is not suitable on account of the small amount of energy it is capable of storing and its heavy no-load running losses. In such cases the load-factor of the equalizing plant is of necessity low and the constant running loss being high the work efficiency must consequently be low. Haulage gear is an instance of a machine whose load curve is usually extremely irregular and for which flywheel storage would therefore not be well adapted; a coal cutter is another instance. The alternative to flywheel storage is the use of a storage battery in combination with an automatic reversible booster. This is more expensive than the flywheel, but it has the advantage of being able to store sufficient energy to deal with any combinations of peaks and depressions in the load curve that can possibly occur. Its no-load running loss is insignificant and the working efficiency is almost independent of the load factor. It has the additional advantage of acting as a reserve in case of a breakdown or of an unusually heavy load on the generating plant, making it possible to shut down the generating plant entirely at times of light load. There are now systems adapted to equalize the loads on alternating-current circuits, so that the battery can, without difficulty, be applied in just such cases as lead to development of the flywheel storage system.—*Abstracted from the Electrician (London), July 10.*

The Equipment of Farms and Country Houses with Electricity.

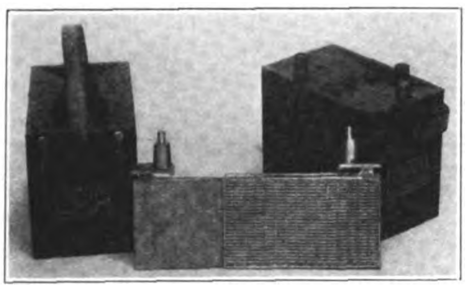
A machine which may be substituted for manual labor should be of great value to the land owner to-day because of the difficulty of obtaining satisfactory farm-hands. In this article Putnam A. Bates contends that this want is largely supplied by the electric motor and that the latter may be expected to relieve the farmer or dairy man of much of the hard work connected with his business. One difficulty which retards the rapid introduction of the motor for this purpose is the high cost of energy in rural districts so that some means of reducing the expense of running motors seems necessary. In the last few years the small internal-combustion engine and the storage battery for stationary service have been so much improved and simplified as to cause them to compare favorably with the better-known types of power-producing apparatus in reliability of operation and first cost. The simplicity of this engine and of the storage battery, together with the economy of fuel consumption of the engine and the efficiency of the battery as a device for storing energy and delivering it when needed and in the quantity required, results in a low operating cost. Still another promising source of power for such small plants is the small water powers scattered throughout the country, many of which have been already developed but abandoned for mill purposes because it was found to be impossible to compete with larger mills. It is evident, therefore, that those not reached by reliable and low-priced electric service may still avail themselves of the electric current and obtain the many conveniences which it contributes, at a cost which should seldom exceed that of an equivalent service from a public-service electric plant. This, of course, will depend upon the design of such small isolated plants. Suitability to the requirements is more important in such plants than in larger ones where the load is more elastic and may be controlled to a considerable extent. Many small power plants have been abandoned as unsatisfactory and extravagant after a short period of operation or are being run at excessive cost with little satisfaction, for no other reason than that the apparatus installed is not well suited to the load. For this reason it is inadvisable to decide the question in an offhand way and leave the installation of the equipment to the contractor since, no matter how honest the latter may be, he is seldom capable of giving the little plant the engineering consideration which it should have. Frequently it is said that the cost of lighting by electricity, in spite of its cleanliness and convenience, is too great when compared with gas, but if the incidental expenses resulting from the use of gas are included in the estimates, it would not infrequently be found that the electric system is, on the whole, considerably cheaper. On the farm there is the greatest opportunity for a successful application of electricity, because in addition to the lighting which, if undertaken alone might not be successful, there are many opportunities for using the small electric motor. The author has himself been engaged in work of this kind for several years past and is convinced that electric power may often be applied profitably to such work. To illustrate his point he describes several installations, some of them on farms and in dairies and one of them at a large country home. Each case shows a surprising number of uses of the motor. The best arrangement is a gas or oil engine driving a generator charging a storage battery. The latter should be large enough to supply the lighting at night and light loads during the day. Such an equipment is not expensive and requires but little attention and that not of an experienced kind.—*Abstracted from the Journal of the Franklin Institute, Philadelphia, July.*

INDUSTRIAL SECTION

ILLUSTRATED DESCRIPTIONS OF NEW AND STANDARD ELECTRICAL AND MECHANICAL APPARATUS

The Universal Electric Storage Battery.

The Universal Electric Storage Battery Company, 65 North Peoria street, Chicago, Ill., has developed an ignition battery in which especial attention has been paid to overcoming the mechanical defects which exist in so many types. This battery is sealed, so that the corrosive acid can not spill nor slop over even if the battery is violently shaken, the sealing compound being an especially



"UNIVERSAL" ELECTRIC STORAGE BATTERY.

strong, smooth and adherent mixture of the company's own discovery. The hardwood box protects the rubber jar containing the element from breakage from sudden shocks. The terminal posts are strong and entirely non-corrodible, being made of alloy and hard rubber, both of which are unaffected by acid.

The electrodes are of the most modern type, and very carefully constructed.

The standard six-volt, sixty-ampere-hour size is suited not only for ignition, but for all sorts of medical and surgical use, for running phonographs, exploding blasts, and lighting miniature lamps.

The New Helios Ignition Battery.

The Helios Manufacturing Company, Bridesburg, Philadelphia, Pa., has placed on the market a new ignition battery which is being received with a great deal of satisfaction by contractors in general. Quite a business is being built up furnishing these ignition batteries for automobile service and selling them in conjunction with small lighting units and for the operation of electrical toys, electrical pianos and other light work. The Helios battery consists of very few parts, and the company is able to produce the battery at a low cost.

The battery is equipped with a new type of rubber case, so constructed that it is strong enough to be used without any auxiliary support. It is supplied with soft-rubber rests and a guard band, relieving the battery from sudden jars in rough handling. It is furnished with terminals of an improved type that can

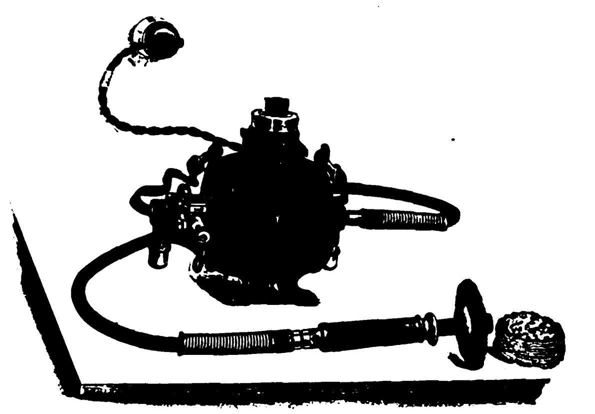
APPLE SIX-VOLT, SIXTY-AMPERE STORAGE BATTERY.

not become loose nor affected by the acid fumes. It is built in the following capacities: Four volts, thirty ampere-hours, twelve pounds; six volts, thirty ampere-hours, seventeen pounds; four volts, sixty ampere-hours, seventeen and one-half pounds; six volts, sixty ampere-hours, twenty-six pounds; four volts, eighty ampere-hours, twenty-three pounds; six volts, eighty ampere-hours, thirty-three pounds.

The Victor Portable Polishing Outfit and Air-Compressor.

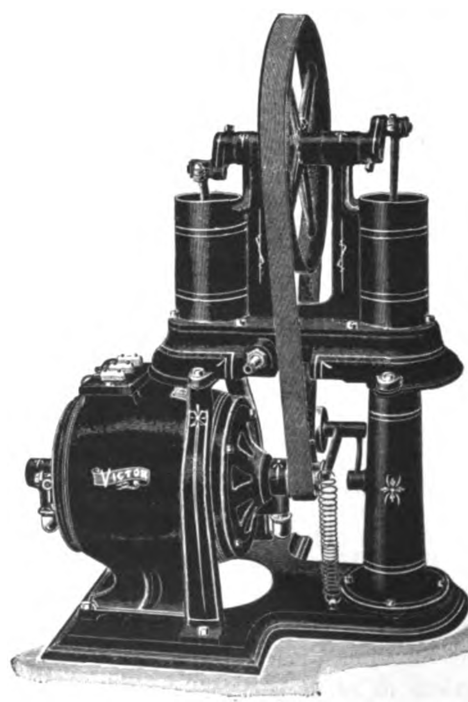
The Victor Electric Company, 55-61 Market street, Chicago, Ill., is the manufacturer of two electrical devices which meet many of the requirements of the contractor for shop and factory use and for executing orders in connection with the wiring and fitting up of residence installations. The Victor portable polishing outfit is neat and powerful, is used principally for cleaning and polishing, and is portable enough to be carried anywhere. It can even be swung from the back of the operator, carried on a carrying strap and belt. The flexible motor shaft enables the operator to reach everything within a number of feet of the motor, and a ten-foot cord attached to the nearest electric socket gives a wide radius of operation. With this outfit metal fixtures, signs, railing and parts of machinery can be easily cleaned and polished in a small fraction of the time necessary to do it properly by hand.

The motor develops one-eighth horsepower, and the entire outfit weighs less than twenty pounds. The buffer and brushes can be easily and quickly changed.



THE VICTOR PORTABLE POLISHING OUTFIT.

The air-compressor was designed to meet the demand for an outfit capable of



THE VICTOR AIR-COMPRESSOR.

supplying a moderately large volume of compressed air at a pressure up to seventy-five pounds. It is supplied with two pistons having two-inch bore by two-and-one-half-inch stroke, and can be safely operated at a speed of 275 revolutions per minute. The motor furnished with the direct-current outfit is capable of developing one-half horse-power, and the winding is calculated especially for this work.

The company manufactures several other types of air-compressors, particularly for dentists and physicians. The company also manufactures the compressor just described mounted on a truck with a pressure regulator and reservoir.

Some Dale Designs for Tungsten Lamps.

The Dale Company, Ninth avenue and Hudson street, New York city, has been at work for some time developing a line of fixtures adaptable to the use of the new high-efficiency lamps, and has produced several specialties adapted to take tungsten lamps. Particular attention is called to the new style shade-holder and adapter illustrated herewith. No adjustment of any kind is necessary with this two-and-one-quarter-inch holder, which goes on the socket easily and firmly and holds the shade rigidly.

New Style Dale Holder.

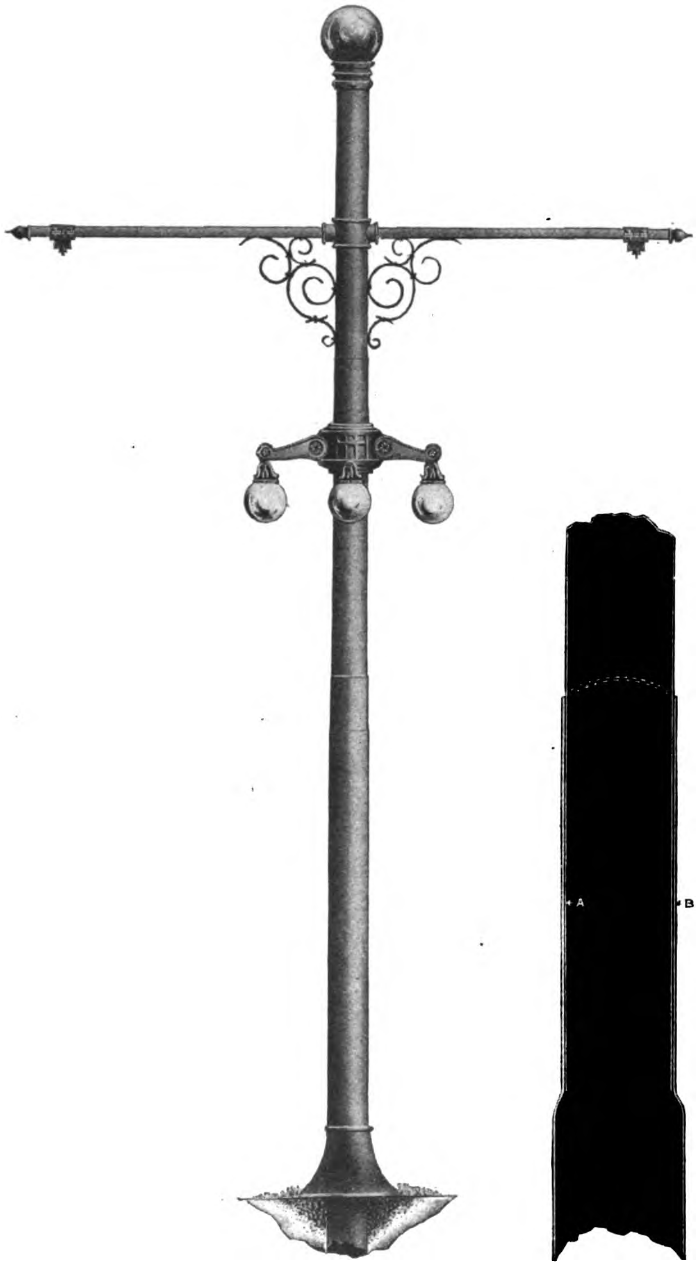
New Dale Tungsten Adapter.

The adapter for tungsten lamps is a simple device which can be used in clusters or fixtures where lamps are at an angle, making it unnecessary to reconstruct or rewire the fixture.

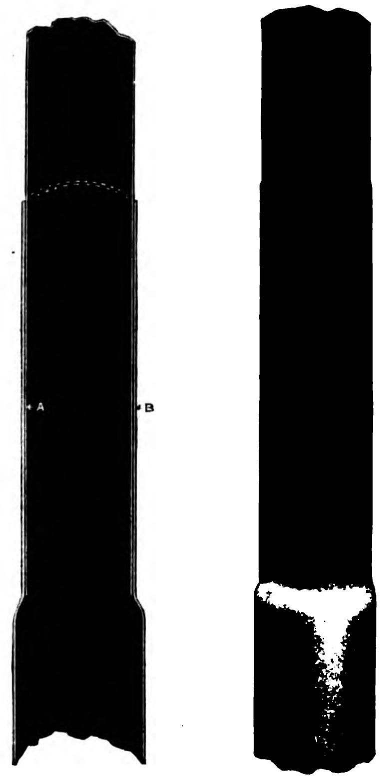
These devices have met with instant success and are being used by central stations, electrical contractors, jobbers and supply men all over the country. But devices are labor and money-savers and increase materially the opportunities for the use of electricity.

Tubular Steel and Iron Poles.

The Pittsburgh Pole and Forge Company, Pittsburg, Pa., is the manufacturer of steel poles and forgings of every description. The company is introducing a line of tubular iron poles, trolley poles, rail benders and car forgings. The accompanying illustrations show the style of pole made by this company, attention being particularly directed to the form of joint used. The tubular steel or iron pole for light and power plants has many advantages. The obstacle preventing the use of tubular iron poles for high-tension transmission work has been overcome by the Pittsburgh Pole and Forge Company by its patent hot process of making a solid swaged joint of the same diameter and thickness for the entire length of joint. It is impossible to telescope the pole either by overload or drop test. Under hydraulic pressure the pole will bend before the joint will give way. It is also stated that this joint is proof against corrosion by water.



Pittsburgh Standard Combination Span and Light Pole.



Pittsburgh Solid-Joint Tubular Pole.

Magnalium.

Magnalium is an aluminum alloy which promises to fulfil many of the expectations which have been based in the past on the utilization of aluminum. Magnalium can be cast in a liquid condition, and the castings machined with about the same facility as brass. The machined surfaces are mirror like and of a silvery color. Screw threads can be easily and perfectly cut, and bored holes are always sharp and clean. The metal does not clog even a very fine file.

When magnalium is cast in dry sand it usually has a tensile strength of 18,000 to 21,000 pounds per square inch, and shows a reduction area of three and one-quarter per cent. Cast in an iron chill, it has a tensile strength of 22,000 to 25,000 pounds per square inch, with a reduction of area of five per cent to eight per cent. The tensile strength of one quality of magnalium containing a somewhat smaller percentage of aluminum equals about 34,000 pounds per square inch. This can be increased to about 42,500 pounds per square inch by proper treatment.

Wire drawn from one quality of this alloy has a tensile strength of 41,000 pounds per square inch, with a reduction area of ten per cent. It will stand a tensile strain of 53,000 pounds if the raw material has been forged before drawing.

Magnalium shows almost no magnetic influences, but its electrical conductivity is about fifty-six per cent of that of pure copper.

Morris R. Machol, 32 Park Place, New York city, is the American agent for the magnalium process.

Electrical Equipment of the Southern Lumber Company's Plant at Bogalusa, La.

One of the most important electrical installations of recent times is that recently completed by the Great Southern Lumber Company, at Bogalusa, La. The importance arises not only from the fact that this is the first installation of this kind in that section of the country, but because it is the largest electrically equipped wood-working plant in the world.

The enormous capacity of this plant has made it necessary to cover a large area, consequently considerable of the wood-working machinery is located at such a distance from the main sawmill that the transmission of power would be almost impracticable through any other means than by the application of electric motors.

A practical mill man will readily understand that there are a large number of complications required where rope transmission is used and that such a system only multiplies the use of belts, pulleys, hangers, etc., as well as adds to the cost of help necessary to keep such apparatus in working order.

The electric drive, when properly installed, does away with long lines of shafting and multitudes of hangers, journal boxes, etc., which have to be continually looked after and kept in repair. It further does away with a great number of expensive belts, which frequently break and have to be renewed or retightened owing to various conditions which must be anticipated.

It is not possible to eliminate all belting in a wood-working plant where electric motors are used as, for example, the small machines in the filing room which may be grouped so that several operate from one motor, or the lumber sorters, blowers and stackers may require short lengths of belting, but even in this case long lines of shafting and gearing may be eliminated. The excellent arrangement and consequent economy of operation of this plant, secured by direct drive, is in a great part due to the efforts of G. U. Borde, of New Orleans, who acted as consulting engineer for this company.

The entire 1,500 horse-power for use about the mill is generated at a central point by General Electric generators and is distributed through cables to motors located at the machines to be driven. The three generators, direct-driven by slow-speed engines and delivering current to the line at 2,300 volts are excited by current from two direct-current marine-engine sets shown in the foreground of Fig. 2. The entire current is carried to the mill through cables in underground steel conduits. The heavy black line running to the left from the power-house in Fig. 1 shows the course of the underground conduit supplying the two planing mills, sorter and stacker and ending with the forty-two motors in the main planing mill.

The wood-working machinery, furnished by the Berlin Machine Company, as well as the auxiliary apparatus and sizes of motors, is listed in the following table:

PLANING MILL NO. 1.

13 16-inch No. 238 trim saws, each direct-coupled to five-horse-power, 1,200-revolutions-per-minute motor.
17 No. 94 planers and matchers, each direct-coupled to thirty-five-horse-power, 900-revolutions-per-minute motor.
2 No. 266 three-saw gang edgers, each belted to thirty-five-horse-power, 900-revolutions-per-minute motor.
1 64-inch No. 285 band rip saw, direct-coupled to fifty-five-horse-power, 514-revolutions-per-minute motor.
1 44-inch No. 283 band rip saw, direct-coupled to twenty-five-horse-power, 600-revolutions-per-minute motor.
1 44-inch No. 281 band rip saw, direct-coupled to twenty-five-horse-power 600-revolutions-per-minute motor.
1 30-inch No. 177 double surfacer, direct-coupled to thirty-five-horse-power, 900-revolutions-per-minute motor.
3 double 70-inch Sturtevant blowers, each direct-belted to 150-horse-power, 600-revolutions-per-minute motor.
All machinery in the filing room is connected with line shafting, belted to a ten-horse-power, 1,200-revolutions-per-minute motor.

PLANING MILL NO. 2.

8 No. 94 planers and matchers, each direct-coupled to thirty-five-horse-power, 900-revolutions-per-minute motor.
1 44-inch No. 281 band rip saw, direct-coupled to twenty-five-horse-power, 600-revolutions-per-minute motor.
4 16-inch No. 238 trim saws, each coupled to five-horse-power, 1,200-revolutions-per-minute motor.
1 double 70-inch Sturtevant blower, direct-coupled to 150-horse-power, 600-revolutions-per-minute motor.

PLANING MILL ON TIMBER DOCK.

1 30-inch by 20-inch No. 1 timber sizer, direct-coupled to eighty-five-horse-power, 900 revolutions-per-minute motor.

DRY LUMBER SORTER.

Dry lumber sorter, driven by one thirty-five-horse-power, 900-revolutions-per-minute belted motor.

LUMBER STACKERS.

8 lumber stackers, driven by eight twenty-five-horse-power, 600-revolutions-per-minute belted motors.

FUEL CONVEYERS.

2 fuel conveyers, driven by two thirty-five-horse-power, 900-revolutions-per-minute belted motors.

CENTRIFUGAL PUMPS.

2 14-inch centrifugal pumps for pumping into log ponds, each direct-coupled to eighty-five-horse-power, 720-revolutions-per-minute motor.

MACHINE SHOP.

1 two-horse-power motor connected to upright drill.
1 two-horse-power motor connected to bolt cutter.
1 three-and-one-half-horse-power motor connected to shaper.
1 five-horse-power motor connected to radial drill.
1 three-and-one-half-horse-power motor connected to machine lathe.

RELAY BLOWER STATIONS.

1 double 70-inch Sturtevant blower, belted to 150-horse-power, 600-revolutions-per-minute motor.

Transformers inside the mills reduce the pressure to 440 volts, at which pressure the motors driving the various mill machines are operated. All of the machines in the three mills of this plant are driven by the General Electric Company's form M induction motors which, on account of their extreme simplicity and sturdiness, are especially suited to this class of work. Moreover the electric motor of such sizes as are used in this work is essentially a high-speed, high-efficiency machine, making it not only possible but highly desirable to connect this direct to the shaft of the tool to be driven. This has been done in all except a few instances, as the higher efficiency obtained with the absence of long belts and lines of overhead shafting more than justifies the extra first cost for individual motors. Saws, shapers, joiners, are all connected direct to the driving motor. The good lighting and entire absence of belts are well shown in Fig. 3, which illustrates the direct motor drive to one of the Berlin band rip saws.

The dust, which is generally such an obstacle to the satisfactory operation of planing mills, is removed by electricity. Seven double blowers are driven by 150-horse-power motors drawing the dust up through a system of pipes. These blowers are distributed through the mill as follows:

One in each of the small planing mills H and I shown in the diagram, two in the rough lumber shed and three in the main planing mill. About eight ounces pressure is maintained by these, which not only carries away dust and fine shavings but also knots and large chips. One of these large blowers is shown in Fig. 4 and the arrangement of the pipes is well shown in Fig. 3.

Fig. 5, showing an eighty-five-horse-power motor connected to a timber sizer, gives a very good idea of the simplicity and compactness of this form of drive. This sizer is in the planing mill on the timber dock as shown in the diagram.

Each of the motors is supplied with a starting device and protecting fuses at the motor so that each machine is a plant in itself and practically independent of the other machines. Fig. 6 shows one of these starting compensators connected to a motor driving a band edger. The fuses at each machine protect that motor and its cable from internal injury, and as the cables are encased in iron conduits fire danger is eliminated.

The entire installation is one that exemplifies the best, the most economical methods of handling lumber, and the cleanliness and flexibility secured by the improved methods used are making the dusty sawmills of the past more and more uncommon.

The Electric Club of Chicago.

The Electric Club, of Chicago, Ill., is to be addressed at its August meeting by William D. Day, contract agent of the Sanitary District of Chicago, on the subject of disposing of the current generated at the hydroelectric development at Lockport.

Westinghouse Nernst Lamps.

Some interesting developments have been taking place in the laboratory of the Nernst Lamp Company, lately, and as a result, it is now only a question of the time required to perfect manufacturing detail, until the company will show some entirely new units.

The Nernst Lamp Company, it will be remembered, was the pioneer in bringing out a high-efficiency incandescent unit, when the original lamp was put on the market, and for some time thereafter it stood alone in the high-efficiency field. Then came in fast succession, the metallized filament, the tantalum and the tungsten. Undoubtedly, besides bringing about a reduction in lighting bills that opened up new fields for many central stations, the Nernst had its effect in stimulating the developments referred to above.

Its own further development in point of efficiency is a matter that has been looked forward to with considerable interest, for the Nernst system has many advocates.

One of the new units which is now ready for the market, it is stated, shows a mean hemispherical efficiency of 1.12 as against 1.65 shown by the corresponding old unit. This represents an improvement of thirty-two per cent and will make competition very close. When the circumstances are taken into consideration, this improvement not only does not seem extraordinary, but it indicates that a still higher efficiency may yet be reached. Just as the efficiency of a filament lamp depends upon the material of which the filament is made, so does the efficiency of the Nernst depend upon the glower material. This material is still in the development stage and there are so many different elements that may be used, offering so many different combinations that the present combination representing a thirty-two per cent increase, may be looked upon as only a step in its final development.

There are other features besides efficiency, however, that must be taken into consideration in selecting a lighting system. Maintenance is scarcely of less importance. In fact, maintenance must be added to efficiency to get the total operating cost per kilowatt-hour before a just comparison of systems can be made. The new single-glower units, of which there are four, *i. e.*, sixty-six, eighty-eight, 110 and 132-watts, respectively, are to be provided with screw base renewals; that is, the renewal part of the lamp will be screwed into place just as in ordinary incandescent-lamp practice. This represents a marked improvement in Nernst the debatable questions in connection with the Nernst system. Because it is an intermediate system between the ordinary incandescent and the arc, human nature naturally expects it to have all the advantages of the former and none of the disadvantages of the latter. As a matter of fact, its maintenance has shown up satisfactorily in large installations justifying an attendant and in small installations having a maintenance contract with the lamp company or a local lighting company. It is chiefly from isolated installations where some one unfamiliar with electricity undertakes to look after the lamps, that criticism has come. Such as these will find in the new renewals something that they can handle without doubt of obtaining satisfactory results.

A point to the advantage of the Nernst system is its wide range of units giving uniform illumination throughout an installation, including windows and the exterior, no matter how diverse the requirements. The new units with four different sizes in the single-glower, will further increase this range. Taste in illumination varies all the way from an entirely concealed system to myriads of small units peeping out from every point that will hold a lamp. The Nernst system is applicable to practically every effect except the latter extreme, which more properly comes under the head of decoration than of illumination.

Downward distribution remains a prominent characteristic of the system, rendering the use of reflectors entirely unnecessary.

When the Nernst system was first introduced it was badly handicapped by being suitable for alternating-current circuits only. A couple of years ago direct-current lamps were brought out and proved successful. The new units will operate equally well on either alternating or direct current, 110 or 220 volts.

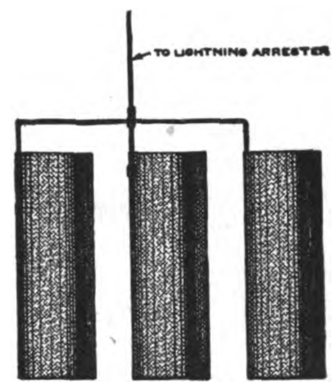
For Squealing Commutators.

The Joseph Dixon Crucible Company, Jersey City, N. J., reports that its graphite brushes, which are made in only one quality, are giving most excellent satisfaction. They frankly acknowledge in their literature that a one-quality brush is not adapted to all conditions, but do say where their brushes are adapted they give unexcelled service. Their use results in the commutator's taking on in a short time a highly polished surface, smooth and well rounded. They state that since the installation of their own electric plant some eight years ago, they have not had occasion to turn down their commutators, and reasonably attribute the condition of the commutator to the use of their graphite brushes.

The Federal Cartridge Ground Plate.

The Federal cartridge ground plate commends itself to all practical men who have wrestled with the problem of making satisfactory ground connections in either telephone, street railway or electric lighting work. By its use a practically perfect ground can be secured at a minimum of expense and trouble.

This device is gotten up in standard sizes with a specific area of plate and size of ground wire. The copper surface is completely covered with the proper grade of charcoal for securing the best ground. The whole is incased in a netting which holds the charcoal securely in place while handling, but breaks down when installed, allowing the earth to mix with the finely



TYPICAL MULTIPLE INSTALLATION CARTRIDGE GROUND PLATES. PATENTED.

divided charcoal. The netting is meant to disintegrate rapidly as soon as the cartridge has been buried in moist earth. The heavy copper ground wire is firmly secured to the copper plate through its entire length so that there is no chance for a break or loose connection.

Each complete plate is put up in a cylindrical cardboard case which is for transportation only and is, of course, removed when the plate is put in the ground. The hole can be made easily with a standard post-hole digger so that the labor of installing is light.

The manufacturers suggest that a piece of fibre conduit be used to protect the wire from the ground plate to a point well above the surface of the ground. A rope drain fitted on the post or wall will lead considerable rainwater into this fibre conduit and so direct to the ground plate, insuring moist earth around the plate.

This ground plate is manufactured by the Federal Electric Company, Lake and Desplaines streets, Chicago, Ill.

lamp practice and will not only reduce the cost of maintenance but will permit it to be done by any one.

Maintenance has always been one of

A NEW FORM OF DIRECT-CURRENT AMMETER AND VOLTMETER.

BY P. MAC GAHAN.

There exists a considerable demand for a line of small-size direct-current switchboard ammeters and voltmeters of the highest grade and accuracy, so constructed as to be low in price.

Recent improvements in factory methods and in design features by the Westinghouse Electric and Manufacturing Company have rendered possible the production of a small-sized switchboard instrument of the permanent-magnet type, at a price as low as that of the best moving iron instruments previously available. The result has been the instruments herein described, which possess unique features and advantages not previously obtained with any type of construction. These instruments are made as ammeters and voltmeters and are mounted in neat black Electrose cases, five inches in diameter, rear-connected, with circular beveled-glass front-plates.

Fig. 1.—Westinghouse Direct-Current Voltmeter.

The use of a case made from insulating material instead of metal gives a degree of insulation not usually found in small instruments. Owing to the peculiar self-shielding form of the permanent magnets, an iron case is not necessary for shielding against the effects of external fields.

The meters are supported by means of brass studs projecting from the rear of the case, serving at the same time as terminals.

The voltmeters are made self-contained, including resistance, in any capacity as high as 300 volts, and the ammeters are operated from external shunts, the shunts of the capacities up to and including seventy-five amperes being mounted directly on the meter studs.

The scale divisions are uniform and the total length is almost the same as that found in the usual seven-inch-diameter meters.

From a technical point of view the most interesting feature of these instruments is the "single-air-gap" type of construction, which differs considerably from the original D'Arsonval bipolar magnet with two cylindrical air-gaps in series.

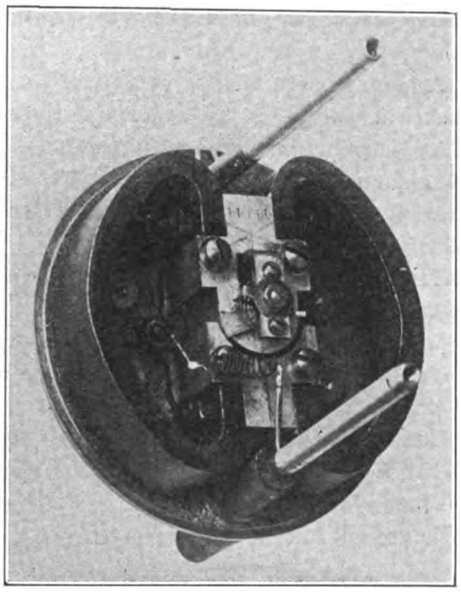


Fig. 2.—Internal View of Meter Mechanism.

The principal advantages of the single-air-gap construction in permanent magnet meters are as follows:

1. The possibility of removing the moving element from the magnetic structure without interfering with the magnets or removing their pole-pieces.

2. The coil balancing the weight of the pointer.

3. Single air-gap means that larger air-gap clearances may be used without making the total magnetic reluctance of the air-gap too high.

The removability of the permanent magnets is really of the greatest importance to the user who desires to do his own repair work on the premises.

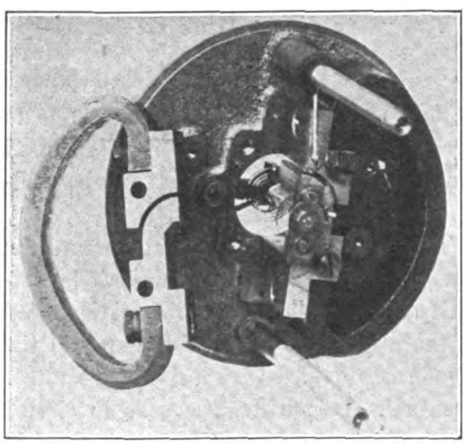

Fig. 3.—Method of Removing Permanent Magnet.

Fig. 2 shows an internal view of the meter mechanism with the case removed.

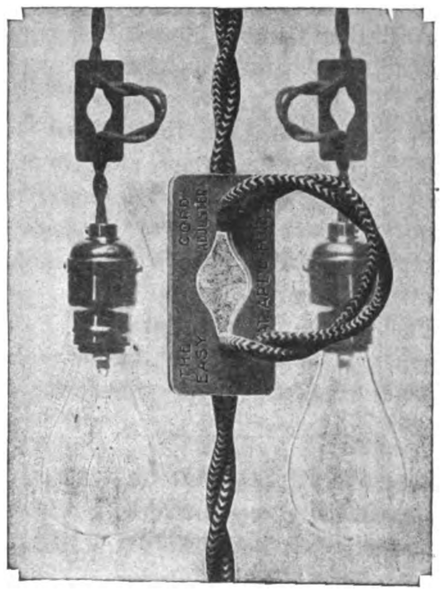
Fig. 3 shows the process of removing the permanent magnets when repairs become necessary.

The principal applications for this class of instrument will be for small panels, such as for rectifier outfits, battery charging, small isolated plants, small marine plants, or even on regular large switchboard work where a small-sized instrument is desirable.

The low price is due to the economic disposition of the material used, the light weight, and the fact that there are no hand operations used in manufacture, aside from the assembly. The parts are all machine-made in large quantities, with a highly organized and accurate tool equipment, the assembler merely attaching these parts together without further fitting.

The Easy Cord Adjuster.

One of those simple little things that anybody ought to have thought of is the "Easy" cord adjuster, the use, simplicity



The "Easy" Cord Adjuster.

and advantages of which are clearly shown in the accompanying illustration. This little specialty is made of the finest grade of red fibre. It will be seen that it contains a slot through the centre, running lengthwise. This slot is made considerably wider at the centre, which permits a double cord to be easily inserted and pulled through any desired length. The tapering ends of the slot hold the cord firmly and keep it from slipping. The dimensions of the "Easy" cord adjuster are two inches by one inch by one-sixteenth inch and one hundred weigh ten ounces. W. N. Matthews & Brother, of St. Louis, Mo., the manufacturers, state that they have sold thousands to contractors and jobbers all over the United States.

New Orders.

The General Electric Company announces that the following orders for new apparatus have been recently received:

Isthmian Canal Commission—Six vertical Curtis turbine units, 1,500 kilowatts, twenty-five cycles, 2,200 volts, each complete with individual base condenser, air and circulating pumps and necessary piping; electrical equipment for one twenty-ton traveling crane; four thirty-five-kilowatt, 125-volt, direct-current turbine-driven exciters; four 500-kilowatt, 600-volt, rotary converters, each complete with three air-blast type transformers; six 100-kilowatt, 2,200-6,600-volt, single-phase, oil-cooled transformers; six 110-kilowatt, air-blast type transformers; two switchboard equipments.

Mitsui & Company, Japan — Fifty GE-52 railway-motor equipments, also rotary converters, transformers, etc.; twenty GE-52 double-motor equipments, with headlights and spare parts; three 1,000-kilowatt alternating-current generators.

Australian General Electric Company—Seventy four-motor type M control equipments for GE-81 railway motors.

Santos Dock Company, Brazil—Six 3,000-kilowatt transformers and five fifty-light constant-current transformers; one motor-generator set; 628 arc lamps; one switchboard; miscellaneous small motors and transformers.

Pueblo Tramway Light and Power Company, Mexico — Ten water-cooled, 1,500-kilowatt, sixty-cycle transformers.

More Electrical Machinery for Guadalajara — Large Extension to Juanacatlan Plant.

The Compania de Transvias Luz y Fuerza de Guadalajara, South America, which company is the result of the combination of the two former electrical companies of that city, and operates not only the entire lighting system, but also the railway system of Guadalajara, have en route to Mexico a large order for additional electrical machinery which was bought from Messrs. G. & O. Braniff & Company, of Mexico City.

In order to meet the increasing demand for electrical power in Guadalajara, this company, finding that their power-generating stations at La Junta and Juanacatlan were insufficient, found it necessary to purchase a 750-kilovolt-ampere, modern, Westinghouse, three-phase, belted-type generator, which will be installed at Juanacatlan. This new generator is but one of the four which will be installed as needed.

The latter station was one of the first electric-power plants in the country; the original installation consisting of single-phase machines, which were added to from time to time by other machines of the same type as growth necessitated.

A more modern method of transmitting electrical energy is by means of three-phase current, on account of the saving of amount of copper required in the transmission line, and is now almost universally in use.

The Westinghouse Electric and Manufacturing Company, of Pittsburg, Pa., is supplying the new electrical machinery. This extension was necessitated not only by the operating of electrical railways in Guadalajara, which now have been in service for the last several months, but also by the additional power required from their present and new subscribers.

The "Patterson" Wireless Dry-Battery Holder.

Stanley & Patterson, 23 Murray street, New York city, have placed on the market a wireless dry-battery holder which presents many advantages for the user of dry batteries for any purpose. This holder eliminates binding-posts and wire connectors and is made to take from one to six cells. If more than six cells are used any combination of holders may be utilized to fit the requirements.

THE "PATTERSON" WIRELESS BATTERY HOLDER.

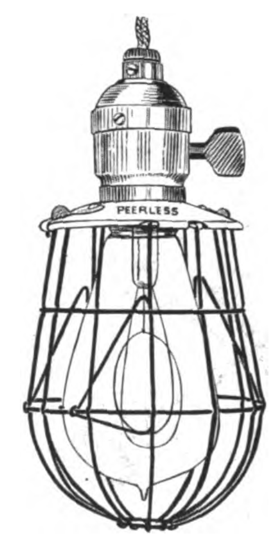
The cells used with this holder are the same as standard two and one-half by six-inch cells, except that a thread is rolled at the upper end of the zinc cup and the carbon is provided with a flat-butt contact terminal. In putting the cells in circuit all that is necessary is to screw the cell into one of the sockets the same as an incandescent lamp.

A feature of one form of the wireless battery holder is the automatic bridge, which comes into action, closing the circuit between the adjacent batteries, if it should be necessary to remove a dead or defective cell from circuit, and there was not another cell available at the moment. When a new cell is procured it is simply screwed into place, and the power of the new cell is added to those already connected up.

A New Lamp Guard.

The accompanying illustration shows one application of the "Peerless" lamp guard, manufactured by the Greenwood Manufacturing and Supply Company, 141 Milk street, Boston, Mass.

This lamp guard has a canopy-shaped, divided metal top, which is hinged to both sides of the cage and has a swivel catch, which fastens it rigidly to the sockets. The guard is made with tops to fit snugly to all styles of sockets, whether metal, porcelain, hard rubber or molded mica. It is made in one piece, and gives maximum rigidity with minimum obstruction to the light. The flat metal tops are nicely finished and nickel plated and the wire parts are coated with pure tin.



THE GREENWOOD "PEERLESS" LAMP GUARD.

Holophane Convention.

The fourth annual convention of sales, engineering and manufacturing departments of the Holophane Company was held at Hotel Sagamore, Lake George, July 12 to 18. The party, consisting of some forty salesmen, department heads and executive officers, in addition to whom were the wives of a half-dozen of the men and several invited guests, making a party of over fifty.

Conferences on matters of business and policy occupied the mornings, the men engaging in sports and pleasure jaunts in the afternoons. A number of very important matters were discussed and plans adopted which will greatly enlarge the scope of the Holophane Company's work in future. Announcements of these changes will be made shortly.

Current Electrical News

DOMESTIC AND EXPORT.

A MILLION-DOLLAR LIGHT AND POWER MERGER—Following a meeting of the directors of the People's Light, Heat and Power Company on July 23, it was announced that a merger of that company with the Home Light, Heat and Power Company, both of Springfield, Ohio, would be effected in the near future. The capital stock of the new company will be $1,000,000. Columbus, New York and Boston men are interested in the new company.

PORTLAND RAILWAY, LIGHT AND POWER COMPANY TO SPEND $1,000,000—The contract has been let by the Portland Railway, Light and Power Company for the building of an underground system of conduits and cables in the business district, as required by city ordinance. The contract amounts to over $1,000,000, and was awarded to the engineering firm of William S. Barstow & Company, of New York. With the installation of the new system, current service to consumers throughout the business district will be changed from a 500-volt direct and a 220-volt alternating-current to a 220-volt direct-current when the system is complete, which will mean the changing of all motors in the underground district now installed to 220 volts direct current.

BOSTON INDEPENDENT TELEPHONE COMPANY TO GET BUSY—The Metropolitan Home Telephone Company, which received a franchise from the city of Boston in December, 1906, is finally taking steps toward beginning construction of its independent telephone system. Under the terms of its franchise, the company must begin construction before January 1 next and have in operation before January 1, 1910, a telephone system adequate for the service of 20,000 subscribers. A system for 100,000 subscribers must ultimately be in operation. In consideration of the franchise, the company will furnish the city with free telephones in the ratio of one telephone for each 2,000 of population of the city, additional telephones to be paid for by the city at a discount of thirty-three and one-third per cent from the company's established rates.

OREGON TELEPHONE CONSOLIDATION—It is rumored that a consolidation of the Home Telephone Company and the Pacific Telephone and Telegraph Company is in prospect, and will take place as soon as certain details can be harmoniously arranged. This proposed combination of interests is reported to have been under serious consideration by the officials of the rival telephone companies since the first of the year, during the time negotiations were being carried on for consolidation of the systems of the Pacific Telephone and Telegraph Company and the Independent Telephone Company, at Seattle. Though greater obstacles will have to be overcome in Portland in operating the systems of the rival corporations than in Seattle, owing to franchise provisions and dissimilarity of apparatus, yet it is said that a practical plan has been formed.

ELECTRIC LIGHTING.

HEPPNER, ORE.—The electric plant at Heppner was destroyed by a cloudburst on July 13.

MUNNSVILLE, N. Y.—The city of Munnsville is to build an electric light plant and displace the present street oil lamps.

SALEM, OHIO—The Salem Electric Light and Power Company is completing plans for the construction of a new power-house.

LIMA, OHIO—At a meeting of the city council held on July 6 it was decided to employ an electrical engineer to prepare plans and estimates for the building of a city electric light plant.

ATKINS, ARK.—The town council of Atkins has granted a thirty-year electric light franchise to W. F. Turner, of Atkins, who will at once proceed to have an electric light and power plant installed and put in operation.

KEENE, N. H.—Stockholders of the Keene Gas and Electric Company and the Citizens' Electric Company have voted to consolidate the two properties. The former company is to issue $50,000 four per cent bonds to be exchanged share for share for the Citizens' company.

WEAVERVILLE, N. C.—The certificates of incorporation of the Weaverville Electric Company have been received. The charter is granted to R. S. Howland, John H. Carter and G. W. Eppes, all of Asheville. The powers granted in the charter are broad and inclusive.

BUTTE, MONT.—At the annual meeting of the stockholders of the Butte Electric and Power Company held in Jersey City, N. J., on July 15, the retiring board of directors was re-elected, with the exception that G. F. Panfield was elected in the place of Rudolph Kleybolte.

HATTIESBURG, MISS.—G. L. Hawkins, of the banking firm of F. W. Foote, is one of the leading interests in a company which has laid about nine miles of street railway in this city. The company has practically negotiated the sale of their bonds and will soon have the necessary money to buy cars and other equipment. New work will probably be started in thirty days.

PINE BLUFF, ARK.—Ralph L. Crump, of New York, representing the Equitable Security Company, has bought the property of the Pine Bluff Light and Water Company, including the gas, electric light and water plants, for $450,000. The sale was under authority of the United States Circuit Court, and was a matter of formality, Crump representing the company's bondholders.

WOONSOCKET, R. I.—The common council, on recommendation of the joint standing committee on street lights, comprising Councilmen Rhodes, Dulude and Cornell and Alderman Mullen, has adopted a resolution contracting with the Woonsocket Electric Machine and Power Company for arc lights for five years at $120 a year and for forty-candle-power incandescents at $30 a year.

CLINTON, MASS.—The first vote in connection with the purchase by the town of the Clinton Electric Light and Power Company was taken at a special town meeting on July 14, when the report of a special committee recommending an appropriation for further investigation into the matter was adopted. The vote was in favor of municipal ownership, being 223 to 27.

RALEIGH, N. C.—The state has authorized the Central Carolina Power Company, which built and operates the plant at Buckhorn Falls, on the Cape Fear River, to change its name to the Carolina Light and Power Company; to change its office from Fayetteville to Raleigh, and to increase its capital stock from $1,000,000 to $3,750,000. The Electric Bond and Share Company is the principal stockholder. James D. Mortimer, of New York city, is president.

TITUSVILLE, N. Y.—The plant of the Titusville Electric Light and Power Company, together with its bonded indebtedness and all of its other perquisites, has passed into the hands of John L. and J. C. McKinney, who have organized a company consisting of themselves, R. E. Dickinson and Fred Woodring. Mr. Dickinson will be secretary and treasurer and Mr. Woodring will act as superintendent, a position which he has held in the plant for the past three years. The purchase price was approximately $75,000.

NIAGARA FALLS, N. Y.—The Niagara Falls Power Company has let contracts for an addition to the transformer house of its Canadian Niagara Power Company across the river. It is expected that the plant will be ready for operation by October 1. A new set of dynamos will be installed, and the output of the plant, which is 20,000 horse-power, will be increased to 32,500 horse-power. The Niagara Falls Power Company is now stringing a new transmission line between Niagara Falls and Buffalo, to enter Buffalo just east of Ferry street.

TELEPHONE AND TELEGRAPH.

WEST CHESTER, PA.—The Millway & Rothsville Telephone Company has been organized, with Dr. H. Walter, of Rothsville, as president.

AZUSA, CAL.—The Covina Home Telephone Company has opened its branch exchange. It will serve about 400 patrons in Glendora and Azusa.

TACOMA, WASH.—Arrangements are being made for the construction of a telephone line from Ashford, in the Succotash Valley, to Longmire Springs, on the west slope of Mount Rainier.

PHOENIX, ARIZ.—The board of supervisors have granted the People's Independent Telephone Company a franchise, extending to every part of Maricopa County, for a period of fifty years. The company first asked for a perpetual franchise, but the board would not grant it.

LITTLE ROCK, ARK.—The North Louisiana Telephone Company is constructing a line from Ruston, La., to El Dorado and has a contract with the Rock Island to extend the line to Little Rock. It is said to be the intention to put in a copper circuit and operate a long-distance line from Ruston to Little Rock and intermediate points.

SNOHOMISH, WASH.—Acting under instructions from the Chamber of Commerce, a committee is circulating an agreement of incorporation for the purpose of organizing a home telephone company. For several weeks the independent company has been boycotted for cutting off free long-distance territory and giving it to Everett.

PEKIN, ILL.—The directors of the Farmers' Mutual Telephone Company will hold a meeting in Pekin on August 1 to discuss plans for the building of a new line, or perhaps purchasing the old independent line. At a meeting in Pekin recently the secretary-treasurer, Arthur Becker, was authorized to secure quarters in Tremont for the head office, also to collect up the subscriptions for stock.

BELLEVERNON, PA.—Application has been made for a state charter for the Westmoreland & Fayette Telephone Company. It is to be capitalized at $1,000, divided into forty shares. The stock is said to be oversubscribed. The intention is to build farmers' lines in this vicinity, also connecting the towns of Bellevernon, Fayette City, Perryopolis, West Newton, Smithton, Monessen and Webster.

ONEIDA, N. Y.—A new independent telephone company has asked for a franchise to construct lines and cables in this city. It is understood that a number of local capitalists are interested in the venture. It is understood that the new company, if it secures its franchise, will at once commence work and will open an office here for business, connecting with Syracuse and Utica and other places near here.

VANCOUVER, WASH.—The franchise of the Washington Home Telephone Company in this city has been sold to H. J. Roake, who, with several local business men, will at once begin the work of constructing the exchange. The new company will be formed with local officers. The construction money will be raised by Vancouver men, and no bonds will be sold. It is expected to have telephones in operation by January 1, 1909.

WHEELING, W. VA.—At a meeting of the directors of the Belmont Telephone Company final action was taken in regard to issuing $100,000 of new preferred stock to make extensive extensions of the system and to redeem the greater part of the outstanding bonds. The extensions of the company's system proposed will take in a good part of eastern Ohio, and all of Belmont County that is not already included in the circuits.

MULLEN, NEB.—The Hooker County Telephone Company has elected the following officers: Dr. D. A. Walker, Mullen, president; F. A. Meidell, Seneca, vice-president; Charles Rodgers, Mullen, treasurer; A. L. Dawson, Seneca, secretary; Ross Fleming, Theron E. Evans and M. R. Fessenden, of Seneca, directors. A new $140 switchboard has been placed in Mullen and gives this line free exchange with the lines running to Brownlee.

SALTILLO, MEXICO—General Geronimo Treviño has been granted a telephone concession by the government of Coahuila. The concession exempts from either state or municipal taxation the capital that will be invested in the installation of a telephone line from the hacienda La Bahia to the town of Muzquiz, Coahuila. He has also been granted permission to use the streets and roads to place the poles and in return agrees to transmit free of charge all official communications.

CHESTNUT MOUND, TENN.—A new enterprise, to be known as the Chestnut Mound Home Telephone Company, has been launched. A meeting of the stockholders has been held, perfecting an organization, electing the following temporary officers: L. C. Thompson, president; A. H. King, vice-president; J. P. Elrod, secretary; F. C. Hargis, treasurer. This is a home institution and connections will be made with all the nearby towns and on to Nashville by way of Gordonsville will be the outcome.

NEWCASTLE, PA.—Plans to merge a number of small independent telephone companies in this locality may result in the formation of a central company, to be known as the Inter-State Telephone Company. If the project is consummated the central company will have $100,000 capital and will control about 3,500 telephones. The companies located in Plaingrove, New Wilmington, Mt. Air, Blacktown, Slippery Rock, Harrisville and New Bedford in this state and Beaver and North Jackson in Ohio, are to be included in the merger.

LANCASTER, PA.—The Landisville Telephone Company has been granted a charter. Residents of Landisville and the surrounding country, objecting to the prevailing toll charges, decided to construct their own line, a large portion of which has already been erected. In addition to Landisville, it will reach Rohrerstown, Bamford, Silver Spring, Garber's Mill, Salunga, East Petersburg and Mechanicsville. The directors of the company are: J. M. Trout, H. H. Koser, P. W. Baker, Ezra Miller, J. L. Minnich, D. R. Stauffer, C. C. Greider, J. W. Kreider, H. W. Minnich, S. N. Root, H. B. Stauffer, F. H. Shenk and A. H. Hoffman.

HARRISBURG, ARK.—The Going Telephone Company was organized recently at Harrisburg. The officers elected were: L. C. Going, president; W. N. Harris, vice-president and general manager; May E. Hart, secretary and treasurer; J. C. Mitchell, auditor. The company is capitalized at $50,000, of which $35,000 has been subscribed. It is expected that within the next six months about $25,000 will be expended in the building and acquisition of telephone exchanges and long-distance lines in and to the towns in eastern Arkansas. The new corporation takes over the Harrisburg Telephone Company's system and franchises. The headquarters of the company will be maintained at Harrisburg.

NAPA, CAL.—The Clear Lake Telephone and Telegraph Company, a new competing line, has been organized and articles of incorporation filed in the office of the county clerk. The company intends to construct and operate new telephone lines in Napa, Sonoma, Mendocino and Lake counties, principally between the following points: From Lakeport to Calistoga, from Lakeport to Cloverdale *via* Highland Springs and Pieta, from Lakeport to Kelseyville and from Pieta to Hopland. The company has a capital stock of $50,000, and the board of directors consists of A. H. Spurr, of Lakeport; H. S. Johnson and F. L. Wright, of Santa Rosa. L. J. Shuman and M. S. Sayre, of Lake County, are also largely interested in the new company.

ANACONDA, MONT.—The directors of the Montana Independent Telephone company have elected the following officers: Harry A. Gallwey, Butte, president; Dr. W. H. Hall, Butte, vice-president; Charles J. Kelly, Butte, secretary and treasurer; Thaddeus S. Lane, Butte, managing director. Patrick Wall, general manager of the East Butte Mining Company, was added to the board of directors, the board now being composed as follows: H. A. Gallwey, M. S. Largey, Patrick Wall, W. H. Hall, H. D. Brown, Thaddeus S. Lane, L. O. Evans, Con F. Kelley, J. T. O'Brien and Charles F. Kelly, of Butte; W. G. Conrad and Thamos Couch, Jr., of Great Falls; Frank H. Clinton, of Anaconda. The Anaconda exchange will be open for business some time in the latter part of July. The eastern extension has been completed to the Nine Mile House, nine miles southeast of Butte. Material has been ordered for the further extension to Logan, Mont., where connections will be made with the Bozeman independent company's lines, and all other independent lines in eastern Montana. This extension will be completed during the summer.

PERSONAL MENTION.

MR. T. G. SEIXAS, of New York, has been appointed general manager of the Pacific Traction Company, of Tacoma, Wash.

MR. R. B. BENJAMIN, president of the Benjamin Electric Manufacturing Company, Chicago, Ill., has gone to London, England, for the purpose of establishing a branch office and factory for manufacturing and handling the company's wireless clusters and lighting specialties abroad. He is accompanied by Mr. B. J. Grigsby, of the engineering department, who will be left in charge upon Mr. Benjamin's return. A stay of from four to five weeks is contemplated.

MR. WILLIAM W. COLE, for many years the able manager of the Elmira Water, Light and Railway Company, has resigned to become associated with the firm of Dodge & Day. Mr. Cole was presented with a handsome diamond ring by Roy H. Smith, secretary of the Chamber of Commerce, on behalf of the railroad employés of the company. The gas and electrical departments also presented Mr. Cole with a diamond scarf pin as a token of their esteem and affection. Mr. Cole is succeeded by Samuel J. Dill.

MR. JAMES F. HEYWARD, who has been appointed general manager of the Maryland Electric Railways Company, with headquarters in Baltimore, was presented with a handsome silk umbrella by the employés of the Citizens' Traction Company, of Pittsburg, when he resigned on July 23 as general manager. The Franklin & Oil City Street Car Men's Union made the presentation and declared that they were sorry to see him leave. Mr. Heyward is not unknown in Baltimore, having been long connected with the local street railway service before the general consolidation. He was the right-hand man of the late Nelson Perin and was the general manager of the City & Suburban line before the merger.

MR. V. R. LANSINGH sailed for Europe on Saturday, July 25, to be gone for six weeks. He will spend the greater part of this time in studying recent European developments in the science of illumination and in going over the situation there as regards Holophane specialties. It is not generally known that Holophane globes were first brought out in Belgium, England and France and that the American company was in the beginning looked upon as a precarious enterprise. The Yankee glassmaker, however, is far in advance of the foreign artisan. Globes produced in America are considered superior to those of European manufacture and are also cheaper, so that the company of which Mr. Lansingh is the head is to-day successful both technically and commercially. It is expected that certain of the styles developed abroad will be acceptable to this market and it is to arrange for an interchange of ideas and experience that Mr. Lansingh is making this trip.

MAJOR E. L. ZALINSKI, U. S. A., retired, has assumed the presidency of the Bureau of Illuminating Engineering, New York city. Major Zalinski, who is naturally of a scientific mind, devoted a great number of years in military research, particularly that of artillery, and is the inventor of a number of devices of war. Major Zalinski is, perhaps, best known in the elctrical field for his work on the diffusing reflector which he, a short time ago, perfected and brought to the fore, and also through the medium of various articles which he has contributed to the advancement of science and art of illuminating engineering. In these he paid particular attention to the diffusion of artificial light. The Zalinski type of diffusing reflectors are now generally accepted and used throughout this and other countries. After perfecting these reflectors Major Zalinski turned over to a well-known company their commercial development. He is now devoting his entire time to the Bureau of Illuminating Engineering, which is prepared to undertake any problems pertaining to the use of artificial light, and has at its command practical, as well as scientific facilities for solving the most intricate propositions. Inasmuch as the bureau affords independent advice to architects and general users of artificial light, it has readily been accepted and is meeting with immediate success.

ELECTRICAL SECURITIES.

There was a broadening of speculation last week, with increased activity, and a number of smart advances, with a number of securities reaching new high levels for the year. For several days there appeared to be a genuine feeling of confidence and buoyancy. The reversal of the judgment of the trial court in the Standard Oil case indicated to many the outer defense which investments may be sure of in the courts of last resort, and notwithstanding the Executive order for action looking to an immediate retrial, there was decided stimulus felt over the present outcome of the case. The favorable turn taken in the affairs of the Westinghouse Electric and Manufacturing Company gave these shares a good impetus upward which was shared by other electrical securities. Reports of a slow betterment in industry in general are widely current. Dividends have been declared on the following electrical securities: Connecticut Railway and Light Company; regular quarterly dividends of 1 per cent on the common and preferred stocks, payable August 15. Books close July 31 and reopen August 17. Montreal Light, Heat and Power Company; regular quarterly dividend of 1½ per cent, payable August 15 to stock of record July 31.

ELECTRICAL SECURITIES FOR THE WEEK ENDED JULY 25.

New York:	*Closing.*
Allis-Chalmers common	11½
Allis-Chalmers preferred	33¾
Brooklyn Rapid Transit	52¼
Consolidated Gas	140½
General Electric	145¾
Interborough-Metropolitan common	8
Interborough-Metropolitan preferred	22½
Kings County Electric	110
Mackay Companies (Postal Telegraph and Cables) common	67½
Mackay Companies (Postal Telegraph and Cables) preferred	68½
Manhattan Elevated	138⅜
Metropolitan Street Railway	30
New York & New Jersey Telephone	110
Western Union	56
Westinghouse Manufacturing Company	78½

In the fiscal year ended February 29, 1908, the Mackay Companies, in their telegraph department, had five months of normal and seven months of poor business. It seems probable that this experience will be directly reversed during the current year. In the past five months telegraph earnings have been more slowly improving, particularly since the first of June. For the remaining seven months it is practically certain that the telegraph business will be much larger than it was a year ago. The cable business of the Commercial Cable Company has been very satisfactory, and it is understood that June business was actually in excess of June a year ago. This result was in a measure made possible, of course, by the fact that the New York-Havana direct cable is now in service, and is proving a large money earner.

The report of the Kings County Electric Light and Power Company, including the Edison Electric Illuminating Company, for the six months ended June 30, shows gross earnings of $1,776,722, compared with $1,672,835 in 1907; operating and general expenses, $824,660; net, $952,062, an increase of $125,304 over the same period a year ago. Replacements and depreciation, $194,998; fixed charges, $303,280, leaving a balance after dividends of $400,000, of $53,784, an increase of $44,818.

Boston:	*Closing.*
American Telephone and Telegraph	122
Edison Electric Illuminating	216
Massachusetts Electric	47
New England Telephone	113
Western Telephone and Telegraph preferred	70

On June 27 last the New England Telephone Company had a total of 233,731 stations of its own, an increase of 5,870 since the first of the year. Including the Southern Massachusetts Company and sublicensees, the company had on June 27 a total of 296,226 stations connected with its lines. Directors of the New England Telephone Company have declared the regular quarterly dividend of 1½ per cent, payable August 15 to stock of record July 31. Books close August 1 and reopen August 14.

Philadelphia:	*Closing.*
Electric Company of America	10
Electric Storage Battery common	30
Electric Storage Battery preferred	35
Philadelphia Electric	9⅝
Philadelphia Rapid Transit	15¼
United Gas Improvement	87½

Chicago:	*Closing.*
Chicago Telephone	138½
Commonwealth Edison	103
Metropolitan Elevated preferred	47

National Carbon preferred	111

ELECTRIC RAILWAYS.

NEW CASTLE, PA.—A new street railway from Beaver to New Castle is planned by the New Castle & Beaver Falls Electric Street Railways Company. Charles Strohecker, of Zelienople, is president.

PALESTINE, TEX.—The Union Central Railway Company has announced its acceptance of the proposition of the citizens of Palestine offering inducements for the road to build into this city. The citizens have pledged the company $25,000 bonus, ten acres for depot facilities and a right of way through the city and county.

ROCHESTER, N. Y.—The Rochester, Charlotte & Manitou Railroad, a trolley line, was sold at auction on July 21 for $12,000 to Kendall B. Castle, a local lawyer, on a foreclosure action brought by bondholders. It is generally supposed that behind the attorney is the Mohawk Valley Company, a branch of the New York Central system.

PHILADELPHIA, PA.—To the accompanying cheers of nearly 500 workmen, the first train of two cars was operated on July 16 in the eastern section of the Market street subway between Fifteenth street station and the station at Second street. Aboard the train, the cars of which were of the steel type used on the elevated section, were President John B. Parsons, P. A. B. Widener, a director; W. S. Twining, chief engineer, and several other officers of the engineering and operating departments of the traction company.

WATERVILLE, WASH.—James Fullerton, of Seattle, has appeared before the county commissioners in behalf of a franchise for an electric line which he proposes to run from a point on the Columbia up the Grand Coulee, with a branch to Waterville. The franchise has not been granted on account of some defects in publishing the notices. Mr. Fullerton said he had secured the right of way the entire length of the line with the exception of three farmers who were holding out and that he did not want to deal with them until after the franchise had been granted.

TACOMA, WASH.—Lucian F. Cook, Henry L. Gray, Charles E. Cutter, C. A. Tonneson and Fred S. Cook have filed articles of incorporation of the Narrows Terminal Belt Railway Company. The company has a capital stock of $250,000. It will construct a trolley line from the end of Center street to Belmarlow Beach. The company also intends the construction of a power plant near American Lake, and a water right allowing it to take 2,000 feet of water per second from the lake has been filed. It is intended to conduct the water from the lake to the Sound, which is 250 feet lower than the lake, in flumes.

GRAND FORKS, N. D.—An ordinance granting to five Grand Forks men a franchise to construct a street railway system in Grand Forks has been given its final reading and passed unanimously by the city council. This means that a stock company will be formed and a street railway built in Grand Forks at an early date. The city already has a line running to the University of North Dakota. This line will be taken over and made part of the new system. The plan is to have a system that will include East Grand Forks. If possible the rails will be laid before the business section of the city is repaved.

LEE'S SUMMIT, MO.—H. W. Gibson, representing the Kansas City Southeastern Traction Company, has been granted a franchise to construct and operate an electric railway on the streets through the city of Lee's Summit. In the granting of the franchise the traction company agrees to begin actual construction of the road inside of one year and to have the road in operation inside of three years, or forfeit the franchise with the city. This line is the proposed line running from Kansas City *via* Leeds, Raytown, Lee's Summit, Lone Jack, thence to Warrensburg, Sedalia and Jefferson City, where they connect with a similar proposed line from St. Louis, which will, when completed, connect Kansas City and St. Louis.

OBITUARY NOTE.

MR. H. G. SHALER, secretary of the Doubleday-Hill Electric Company, Pittsburg, Pa., died in Pittsburg on July 18. Mr. Shaler was a native of Pittsburg and was well known in electrical circles. He was a man of a fine, gentle and generous nature and will be mourned by a host of friends and acquaintances. He is survived by his wife and two children.

NEW MANUFACTURING COMPANIES.

ST. LOUIS, MO.—Grant Electric Company. $3,000. Incorporators: Adolph L. Zuest, Jr.; Fred J. Mayer and Erle R. Jackson. To manufacture and deal in electrical appliances.

BOSTON, MASS.—The National Electric Equipment Company, of Boston, has been incorporated with a capital of $50,000. The president is Charles H. Sprague, of Newton, Mass.

SAN FRANCISCO, CAL.—The Union Electrical Manufacturing Company has been incorporated to do business in San Francisco. It has a capital stock of 50,000 shares at a par value of $1 a share.

NEW YORK, N. Y.—The Kosmos Electric Runabout Company, Manhattan, has been incorporated to manufacture electric vehicles, etc. $100,000. Incorporators: J. H. Kahrs, E. Giovannoni and D. B. Turner, New York city.

READING, PA.—The Reading Chandelier Works is the name of a new concern which is about to engage in the manufacture of electrical and gas fixtures at 440 Woodward street. The plant will occupy the entire three floors and a basement.

SPRINGFIELD, ILL.—The Elgin Electrical Manufacturing Company, of Elgin, has been incorporated to manufacture electrical devices with a capital of $10,000. The incorporators are M. E. Hepburn, L. B. Hamlin, Jr., and C. C. Heywood.

NEW YORK, N. Y.—The Power Equipment Company, of Manhattan, has been incorporated to manufacture engines, boilers, machinery, etc., electrical work. $25,000. Incorporators: L. A. Camacho, New Brighton; G. A. Conover, Bayonne, N. J., and A. M. Mayer, New York city.

LOUISVILLE, KY.—The Ohio Falls Construction Company has been incorporated with a capital of $2,000, to be divided in 200 shares of $10 each, to manufacture electrical supplies. The incorporators are C. A. Duckwall, Theodore Allen, Clifton Brennan and Harry B. White.

INDIANAPOLIS, IND.—Columbia Meter Company, Indianapolis. $10,000. To manufacture electric and other meters. Directors: Gustave A. Schaffer, William H. Pugh and Thomas G. Lee. This company, which has been in business in this city for two years, is incorporated to effect a reorganization.

SALT LAKE CITY, UTAH—The Capital Electric Company has filed articles of incorporation with the county clerk, with $400,000 capital stock, at $1 per share. The officers are: President, R. W. Nicol; vice-president, A. L. Woodhouse; secretary and treasurer, C. W. Corfield. The company takes over the stock of other companies as follows: Butte Electric Supply Company, Electric Fixture and Supply Company, Boisé; Pocatello Electric Supply Company, Idaho Falls Electric Supply Company, Electric Supply and Fixture Company, of Ogden; Salt Lake Electric Supply Company, Electric Manufacturing and Repair Works, Salt Lake; Citizens' Electric Company, Salt Lake; interest in the Utah Electric Company, and now the Capital Electric Company. Of the new stock 174,000 shares will be owned by Mr. Nicol. Twenty thousand shares will be owned by employés of the company, managers, superintendents and the like. The value of the real estate acquired amounts to $173,748.

DATES AHEAD.

Michigan Electric Association. Annual meeting, Grand Rapids, Mich., August 18-21.

International Association of Municipal Electricians. Annual convention, Detroit, Mich., August 19-21.

Ohio Electric Light Association. Annual convention, Put-in-Bay, Ohio, August 25-27.

Colorado Electric Light, Power and Railway Association, Glenwood Springs, Col., September 16-18.

Old Time Telegraphers' and Historical Association, and Reunion of Military Telegraphers, Niagara Falls, N. Y., September 16-18.

Illuminating Engineering Society. Annual convention, Philadelphia, Pa., October 6-7.

American Street and Interurban Railway Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Accountants' Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Claim Agents' Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Engineering Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Manufacturers' Association. Annual convention, Atlantic City, N. J., October 12-16.

American Electrochemical Society. Fall meeting, New York city, October 30-31.

INDUSTRIAL ITEMS.

THE AJAX LINE MATERIAL COMPANY, Chicago, Ill., states that under date of July 10 the examiner in interferences announces that "it is adjudged that the Ajax Line Material Company is the owner of the trade-mark and is entitled to the registration." This is in reference to the trade-mark "Ajax."

THE SPRAGUE ELECTRIC COMPANY, New York, N. Y., has recently opened another branch office on the Pacific Coast. The San Francisco office is now supplemented by one in the Colman Building, Seattle, Wash., in charge of W. R. Hendrey, who is well known in the electrical field on the coast.

W. R. OSTRANDER & COMPANY, 22 Dey street, New York, N. Y., has published the fifteenth edition of their 690-page catalogue and discount sheet. This is one of the most complete listings of electrical apparatus published. The value of the catalogue is enhanced by the careful and comprehensive index, making reference easy.

THE F. BISSELL COMPANY, Toledo, Ohio, has added another postal card to its series of "Bissell Frog" souvenirs, showing the enthusiastic batrachian fishing for orders—and getting them. The company is also distributing some interesting literature devoted, respectively, to Wagner measuring instruments, Perkins snap switches, "Security" conduit rods, and Bryant "New Wrinkle" sockets and Bryant "Chapman" receptacles.

THE HOYT ELECTRICAL INSTRUMENT WORKS, Penacook, N. H., is distributing several bulletins devoted to the Hoyt voltammeter for ignition testing, the Hoyt voltmeters and ammeters for direct current, the Hoyt battery power gauge for ignition batteries, type 35 Hoyt voltmeters and ammeters for direct current for portable and switchboard use, and the Hoyt voltammeter for testing ignition batteries. The company has commenced the publication of a monthly bulletin in which may be found items of particular interest to the automobilist and the user of ignition apparatus.

THE CENTRAL ELECTRIC COMPANY, Chicago, Ill., is distributing an attractive folder entitled "'Tis of the Home We Speak," the circular being devoted to a well-written description of its new lighting fixtures, manufactured by the Price-McKinlock Company, Boston, Mass. The circular should be found of considerable interest to architects, or those contemplating the installation of attractive lighting fixtures. Especial attention is called to the new studios at 264-270 Fifth avenue, Chicago, where a large number of original designs in lighting fixtures are shown.

THE LORD ELECTRIC COMPANY, 213 West Fortieth street, New York, N. Y., has ready for distribution bulletin H, devoted to lightning protective devices. This bulletin gives a brief discussion of lightning phenomena and describes in detail the principles and mechanical and operating features of the Shaw lightning arrester. Several models are illustrated. The bulletin also describes and illustrates the ground points, plates and contacts which it has developed, and considerable valuable data are given concerning the auto-discharge choke-coil, the vertical-unit choke-coil, the laminar-unit choke-coil, and high-tension disconnecting switches.

THE GENERAL ELECTRIC COMPANY, Schenectady, N. Y., in bulletin No. 4603, describes and illustrates an arc lamp especially suited to the illumination of mills and factories, where the vibration caused by machinery and the variation in line voltage resulting from the use of motors for machine drive have made imperative the design of a lamp of this character. This is a multiple lamp, to operate on 220 volts, direct current. Bulletin No. 4600 describes various types of controllers for use with both alternating-current and direct-current motors, on electric cars, locomotives, automobiles, launches, elevators, trains, hoists, etc., and also in rolling mills, machine shops, printing plants and pumping stations. The bulletin describes the controller most suitable for a specific purpose, and contains general data and dimensions which will be found of value to any one contemplating the installation of motor drive.

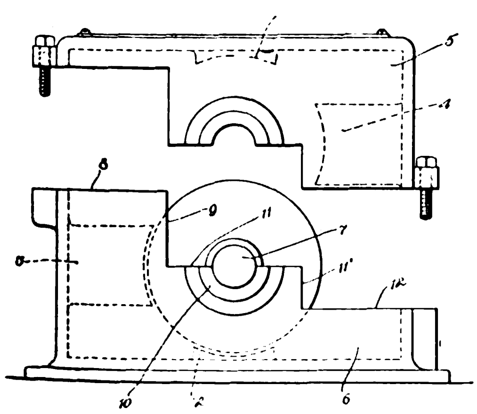
Record of Electrical Patents.

Week of July 21.

893,606. MAGNETIC SEPARATOR. Charles G. Buchanan, Brooklyn, N. Y. The ore is moved by a conveyor through a uniform magnetic field for part of the travel, the exciting magnets being short-circuited during the remainder of the time.

893,618. ELECTRIC TRANSFORMER-FURNACE. Otto Frick, Stockholm, Sweden. A rotatable induction furnace.

893,681. DYNAMO-ELECTRIC MACHINE. William L. Waters, Milwaukee, Wis., assignor to National Brake and Electric Company, Milwaukee, Wis. A dynamo casing separated into two parts along three horizontal and two vertical planes.



893,681.—DYNAMO-ELECTRIC MACHINE.

893,701. MACHINE FOR EXTRUDING METALS. George H. Benjamin, New York, N. Y., assignor to the Coe Brass Manufacturing Company. The metal to be extruded is maintained molten by an electric heater.

893,711. FIELD MAGNET FOR DYNAMOELECTRIC MACHINES. Abe L. Cushman, Concord, N. H. The pole-pieces are provided with removable flaring tips forming substantially V-shaped lateral notches for concentrating the flux.

893,730. RAILROAD-SWITCH SIGNAL. William H. Harris, Stark, Mont. The signaling circuits are closed by means of a knife-edge actuated by bell crank.

893,731. ELECTRIC SIGNAL FOR RAILWAYS. William H. Harris, Stark, Mont. The track is divided alternately into long and short blocks, each of the former being connected in circuit with a succeeding short block.

893,742. LIGHTNING ARRESTER. Ralph D. Mershon, New York, N. Y., assignor to the Westinghouse Electric and Manufacturing Company. A series of grounded discharge paths are connected in multiple and are arranged to have successively higher striking potentials.

893,783. ELECTRIC HEATER FOR SHOE-OPERATIVES' KNIVES. Edwin N. Chandler, Brockton, Mass., assignor to Simplex Electric Heating Company, Boston, Mass. A plate heated electrically against which the knife blades are held by a clip.

893,811. ELECTRICAL CONDENSER. Greenleaf W. Pickard, Amesbury, Mass. The condenser coatings are attached to the glass base by a silicate binder.

893,814. DEVICE FOR PRODUCING ELECTROLYTIC METAL-PLATING. Albert Schmitz, Brussels, Belgium. The metal plate is passed continuously through the plating bath, sliding contacts being provided for collecting the current.

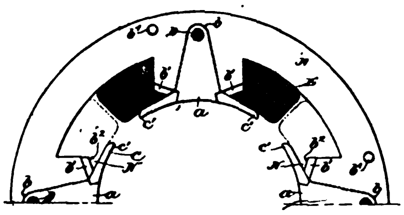
893,816. STARTING DEVICE FOR MERCURY-VAPOR APPARATUS. George Schwarz and Josef Amon, New York, N. Y. The starting device is a plunger in a branch circuit controlled thermally.

893,820. INTERCOMMUNICATING TELEPHONES. Henry C. Thomson, Boston, Mass., assignor to Electric Goods Manufacturing Company, Boston, Mass. A casing for mounting an intercommunicating telephone instrument.

893,835. FIELD-MAGNET FOR DYNAMOELECTRIC MACHINES. Abe L. Cushman, Concord, N. H. The poles have a longitudinal recess extending throughout the length of the pole-piece into which a removable section is inserted.

893,857. FLEXIBLE CONDUIT. George A. Lutz, New York, N. Y., and Clarence C. Sibley, Perth Amboy, N. J., assignors to American Circular Loom Company, Portland, Me. The lining of the conduit has series of rows of perforations at distances apart, the rows being at an angle to the length of the conduit.

893,880. SWIVEL-JOINT FOR ELECTRIC CURRENTS. Augustus B. Smith, Wilkinsburg, Pa. Both portions of the joint are provided with terminals, a rolling current-transmitting device being placed between.



893,711.—Field-Magnet for Dynamo-Electric Machine.

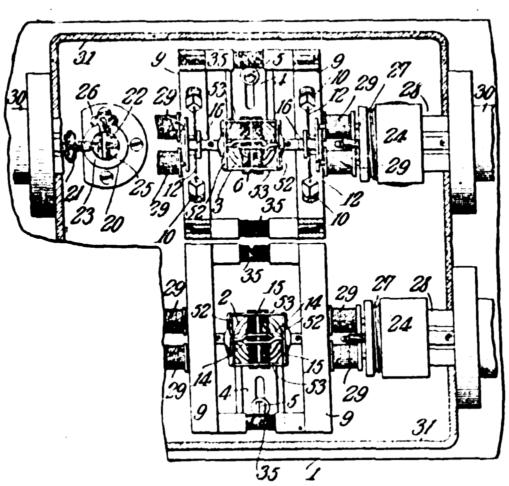
893,891. HAND TELEPHONE SET. George F. Atwood, East Orange, N. J., assignor to Western Electric Company, Chicago, Ill. A waterproof hand telephone, the talking switch being entirely enclosed.

893,902. ELECTRICAL PERMUTATION-LOCK SYSTEM. Henry T. Cleary, St. Louis, Mo. A lock controlled by a number of electric circuits.

893,918. THERMOSTAT. William F. Gossick and Arthur R. Van Valkenburgh, Chicago, Ill. A two-part thermostat, the part containing the heat-responding device being removable.

893,936. ELECTRIC REGULATION. Morris Moskowitz, New York, N. Y., assignor to the United States Light and Heating Company, New York, N. Y. A regulating system for controlling a generator when charging a storage battery.

893,953. TELEPHONE RELAY. Charles W. Underwood, Crowley, La. A relay consisting of two telephone-receiver magnets in series with a telephonic transmitter, and an armature in operative relation to each magnet.



893,953.—Telephone Relay.

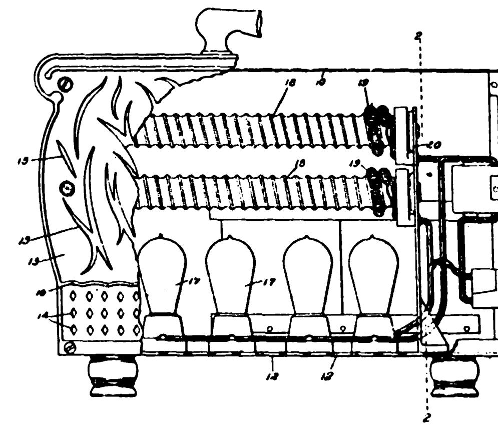
893,979. DYNAMOELECTRIC MACHINE. James Burke, Erie, Pa., assignor to Burke Electric Company. The armature has two windings, one consisting of twice as many turns as the other.

893,994. ILLUMINATED ELECTRIC HEATER. Francis C. Green, New York, N. Y., assignor to Consolidated Car-Heating Company, Albany, N. Y. The heating casing is perforated so as to imitate a flaming fuel bed.

893,997. DISTURBANCE-OPERATED CIRCUIT-BREAKER. Leo D. Haas and Edwin G. Derbidge, San Jose, Cal. The actuating magnet circuit is closed by a pendulum switch whenever the device is disturbed.

894,142. TELEGRAPH TRANSMITTING INSTRUMENT. Frederick H. W. Higgins, London, England. A type-printing telegraph.

894,143. PERFORATING PUNCHING MACHINE, ETC. Frederick H. W. Higgins, London, England. A perforating machine for a type-printing telegraph system.



893,994.—Illuminated Electric Heater.

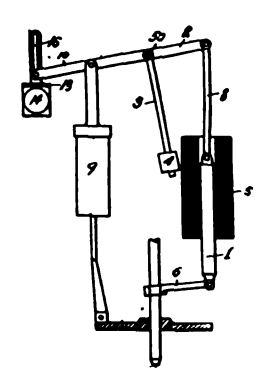
894,144. ROTOR FOR DYNAMOS AND ELECTROMOTORS. Jack Hissink, Berlin, Germany. The end turns of the rotor conductor are enclosed in separate supporting rings.

894,150. LIGHTNING ARRESTER FOR ELECTRICAL CIRCUITS. Ralph B. Ingram, Wilkinsburg, Pa., assignor to Westinghouse Electric and Manufacturing Company. A series of spark-gaps which are shunted by successively decreasing amounts of ohmic resistance.

894,157. PROCESS FOR OPERATING ELECTRIC-ARC LAMPS IN SERIES. Frank M. Lewis, Brighton, England, assignor to General Electric Company. The lamps are controlled by series-regulating coils only.

894,158. ELECTRIC ARC LAMP. Frank M. Lewis, Brighton, England, assignor to General Electric Company. An arc lamp for constant-potential series circuits, which is controlled by a series magnet only.

894,166. MEANS FOR PRODUCING AND UTILIZING RAYS OF LIGHT FOR THERAPEUTIC PURPOSES. Corydon E. Rogers, Seattle, Wash., assignor, by mesne assignments, to the Rogers Therapeutic Lamp Company, Phoenix, Ariz. A reflector for an incandescent lamp.



894,158.—Electric Lamp.

894,167. KEYBOARD. Adolph H. F. Shaar, San Francisco, Cal., assignor to United States Wireless Printing Telegraph Company, Los Angeles, Cal. A plurality of contact levers for telegraphic purposes.

894,170. TELEPHONE REPEATER SYSTEM. Nathaniel G. Warth, Columbus, Ohio. A telephone relay composed of two induction coils and two transmitting devices, the latter being controlled by independent electromagnetic means.

CONTENTS

ELECTRIC POWER IN THE MINE.

In order to keep the mining industry on a par with others, the old and crude methods which employed hand labor largely have necessarily been abandoned. Here, as elsewhere, free use of mechanical power has been the means of cheapening the cost of production and increasing the output of the mines. We first saw the steam engine applied to pumping and later to hoisting, and in recent years compressed air and electricity have been adapted to driving drills and cutting machinery, while the electric motor has largely displaced the old hand-pushed or mule-drawn cars. The interest at the present time centres, therefore, not simply in the extension of the use of power in the mine, but in the kind of power most suitable for all mining purposes. We find the steam engine applied to hoisting, the use of steam-driven pumps for drainage, the application of compressed air for operating drills and other cutting machines—all of which has been done most successfully; and, what is more interesting to us, we have seen the gradual adaptation of electrical means, not merely to supplement the older methods, but actually to replace them.

The first use of electricity was, of course, for lighting, and the advantages of the incandescent system were appreciated. Then came the electric mine locomotive, which soon proved superior to the compressed-air tractor. Next the motor was applied to driving the drills and cutting machines, and here also it seems to be conquering the entire field, for when there is some old device possessing a peculiarly advantageous feature, this may almost always be incorporated in an electrically driven machine which is more easily supplied with power and transported from point to point with less difficulty.

The most recent noteworthy application of electricity in the mine has been its use for driving winding drums. Its superiority for such constant work as driving drainage pumps has long been recognized, and where electric power is available the motor-driven pump is usually selected, but for such irregular work as the driving of hoisting drums, it was thought that the older direct-connected steam engine was unquestionably the better. Even here we have seen the electric motor, when arranged to handle irregular loads economically, displace the simple engine drive and show such excellent results that the method promises rapidly to become standard practice. This last triumph of the motor leaves little work in the mine which can not be performed by some application of electrical energy. The problem of supplying power to the mine is thus greatly simplified, since all the power-generating apparatus may be concentrated in one economically operated station and the energy may be easily distributed with slight loss to any point in the mine. We have here the ideal solution, and one which has long been looked forward to. Nevertheless, it is really surprising to note how rapidly the mines are being converted to the electric drive. An excellent idea of this is given by the mining exhibition which was held recently at London, England, at which a good deal of attention was given to the application of electric power for mining purposes. Fifteen years ago this method was not considered for anything except lighting and signaling. Now it will be but a short time before it has become the standard method in the mine.

THE BRUSIO HYDROELECTRIC PLANT.

Switzerland, a country blessed with great resources of water power, has always been a leader in the development of such sources of power. In later years, the introduction of electrical transmission of energy has added greatly to the value of the waterfalls. Thus it follows naturally that the Swiss engineers should also become leaders in this new branch of engineering. Switzerland possesses no coal mines, and hence was forced to turn to the waterfalls as a substitute for steam or gas power.

The development of electrical transmission has been particularly advantageous for Switzerland, because in that country there are many small industries as well as large. There are not only the silk mills, railways and other lines of work making large demands for power; but a system of home industries is wide-spread, and it can readily be imagined how beneficial to the whole community the distribution of power by means of electricity may be, when it is realized that frequently the demand for power does not exceed one-eighth or one-quarter of a horse-power. Much of this small power is used in the homes for making small parts of clocks, watches, etc., and it is interesting to point out that no other system of power distribution could meet these requirements. Electrical energy is, however, easily and conveniently delivered at any point, in large or small quantities, as desired, and is easily converted into mechanical power at the point required, in a small motor. This is the only method we have to-day of replacing foot-power and enabling the workman to devote his entire attention and energy to directing the operations of his machine. Such consumers are naturally widely distributed, a matter of little moment with the electrical supply company, but prohibitive to distribution of power by any other means. Nor are the large consumers of energy in that country always collected in groups. For these reasons the development of electrical transmission of energy has been a great factor in the building up of the Swiss industries.

In another field of electrical application Switzerland has also gone ahead. During recent years a number of different types of electric railway systems have been installed, including direct-current, single-phase and three-phase equipments, as well as high-potential, direct-current systems. One advantage of this tendency in Switzerland is the avoidance of smoke from factory chimneys or locomotive stacks, a feature of particular value over there where the tourists expect the air to be clear and clean, and where the least trace of smoke would bring forth criticism. And in another way electric traction systems have been of advantage in Switzerland, as they are excellently adapted to operate the many adhesion and inclined railways found throughout the mountains.

In the southern part of Switzerland, as well as in the northern part of Italy, there are many large silk and other mills, many of which formerly were driven by their own steam plants. Practically all of these to-day are supplied from large central hydroelectric stations. Italy unfortunately has few coal mines and comparatively few water powers, hence she is coming to depend upon her neighbor to the north, and draws upon the latter for electrical energy in large quantities.

In view of these conditions in Switzerland the article appearing elsewhere in this issue, in which Mr. Frank Koester describes the Brusio hydroelectric power development and its 50,000-volt Swiss-Italian transmission line, will be read with particular interest. There are a number of notable features about this plant, one of these being the high head of the water—1,300 feet. This drives direct-connected 7,000-volt, three-phase, alternating-current generators, at which potential the current is transmitted across the frontier into Italy. There it is stepped up to 50,000 volts, and transmitted eight and one-half miles to the step-down transformer stations, where it is distributed at different pressures to the various consumers.

Other interesting features of this station are the syphoning system at Lake Poschiavo; the individual switchboard for each generating unit, with its central controlling switchboard or column; the system of reinforced concrete cells for the various high-tension devices; the arrangement of the high-tension busbars, which are not, as in American practice, placed in compartments, but are only separated by reinforced concrete shelves; the complete double-line transmission system; the unique arrangement of the transformer station; and the precautionary measures adopted for protecting the plant against atmospheric disturbances, which are so frequent in this mountainous country. This transmission system may be considered the most notable one in Europe. Owing to the importance of reliability two distinct lines and two step-down transformer substations have been provided. The system as a whole may be taken as an excellent example of modern Swiss engineering.

THE VALUE OF WOOD PRESERVATION.

The electrical transmission systems and the electrical railways are among those industries which use large quantities of timber, and they are naturally feeling severely the rapid increase in the price of ties and poles, which has taken place in the past five years. It is true that both of these industries are looking for a substitute for wood, but even at the present prices there are many places where wood is cheaper than steel. As yet a satisfactory steel or concrete cross-tie does not seem to be available. Such a tie must, of course, be satisfactory in price as well as in its mechanical features. Hence it is of great importance to these industries to prevent, as far as possible, a still more rapid increase in the cost of timber. This can be done if some method of treatment is adopted which will give to the ordinary pole a much longer life than it would have untreated, or which will make it possible to utilize woods which to-day are not satisfactory because they do not resist decay. There is nothing new in this suggestion, as it has been made many times before, and has even been actually put into practice to a limited extent; but it is evident that the true value of such treatment is not yet fully realized, otherwise it would be much more frequently resorted to. In the current issue of the *Engineering Magazine* this feature of the problem is considered by Mr. C. P. Winslow. His discussion is not limited to the value of this process for the electrical industry alone, for he takes the matter up in a broader way. He does, however, point out how the cost of timber may be reduced by a proper treatment, and makes particular reference to the effect that this would have upon the tie problem and the cost of poles for transmission and distribution purposes.

The application of any preservative treatment can not, of course, reduce the cost of the piece of timber, except by making it permissible to employ a cheaper grade of stock. But even in this event it is likely that the cost of the treated piece would be nearly, if not quite, as great as that of an untreated piece of better material; but when one takes into consideration the increased life which the treatment gives, thus saving the first cost of a new piece, at an increased price and the cost of putting it in place, the value of the treatment is evident.

There is also a broader aspect which recently received considerable attention, and that is the preservation of our forests, so that they may supply the needs of future generations, and the avoidance of further destruction of our water powers. Unless the consumption of timber can be reduced we will soon be at the end of our supply, and there can be little doubt that the preservation of timber from decay will become one of the important means of decreasing the drain on our supplies.

As an illustration of the economy of preservative treatment one or two of Mr. Winslow's figures may be quoted, and it should be understood that his contention is not that such a treatment may become profitable in the future, but that the treatment is profitable to-day, since at the slight increase in the cost of the material, the annual charge for ties or poles, as the case may be, is reduced. For example: A thirty-five-foot pole for an electric line, of either loblolly or old-field pine, may be had for about $5 at its origin of growth; such a pole if not treated in any way will last about five years; hence allowing interest at five per cent the annual charge will be $1.15. Treating the butt of the pole with creosote will give it a life of about twenty years, at an increased cost of only about one dollar, so that the annual charge is reduced to forty-eight cents; and, of course, the further from the source of supply the higher the price of the pole and the more profitable will the treatment be. In the same way Mr. Winslow shows that the annual charge for a railway tie may be reduced from 16.8 cents to 10.7 cents by a proper treatment. The untreated tie is assumed to cost seventy-five cents, and to last five years; the treated tie is assumed to last ten years. But even should it last only six years it would still show an annual saving of two-tenths of a cent.

This phase of the problem, the actual saving in the yearly cost of maintenance, is one which will appeal to the constructing and operating engineer, and should lead to a much wider use of preservative treatment than is at present made. One difficulty to-day is the comparatively few places where such treatment may be given; but this is a lack which should be quickly supplied. The preservative treatment has been used in Europe for years past, and its value has been unquestioned, and there is little reason for holding off any longer against it in this country.

ELECTRICITY IN AGRICULTURE.

On another page of this issue we publish a statement by Sir Oliver Lodge of the results which have so far been obtained from the experimental application of electrical stimulation to growing plants. We have already referred to these experiments, which were first made at Bitton, near Bristol, England, and then on a larger scale at Gloucester. There is no information of the results of these latest tests, as, of course, the effect of this year's experiments has not yet been determined.

As we have pointed out before the apparent effect of electrical stimulation is so great, and the energy required so trifling, that practically the only cost of applying this treatment is that of installing the system. This should be very small compared with the increased value of the crops. In several cases an increased yield of thirty to forty per cent was obtained, while the grain from the electrically treated plot was said to be better and brought a better price than that from the untreated neighboring plot. In some cases where an increase in the weight of the harvest was not found there was an increase in its value. This was the case with beets, which contained several per cent more sugar than did those from the control plot. The experiments were repeated again this year, and a little later we will probably have some new facts which may throw additional light on the problem.

It is much to be desired that similar tests be conducted elsewhere, on a scale at least as large as that in England, where altogether about twenty acres are used in the experiments. It would be well also to have tests conducted in as many different parts of the world as possible, because the value of the treatment might be much greater in northern latitudes, for example, where there is less sunlight, than nearer the tropics. In some climates and on certain soils it might have little or no value; indeed it might, perhaps, be detrimental. It might even be found that an electrical treatment would take the place of fertilizers, as some agriculturalists contend that the chief value of the manures is to render the plant food contained in the soil more available. The vigorous growth produced by electrical stimulation may possibly enable the plant to secure its food without other assistance. It is true that we now have one or two methods of preparing artificial fertilizers from atmospheric nitrogen, and if these live up to their present promises, the fertilizer situation may be somewhat relieved, if not saved; but these fertilizers are necessarily expensive, and the cost of using them would be much more than that of electrical stimulation. The problem as presented is interesting, and well worthy of careful study and investigation.

Record-Breaking Telegraph Sending and Receiving.

During the recent Democratic National Convention at Denver, the chief telegraph operator of the New York *Sun,* George W. Conkling, performed a feat in telegraph sending which is unparalleled for speed, accuracy and endurance, even in this branch of engineering where heroic work is by no means the exception.

Working over a wire that stretched more than half way across the continent, about 2,500 miles, Mr. Conkling attained the high speed of 3,136.20 words an hour, or 52.27 words to the minute, a record which has never before been equaled anywhere.

Furthermore, Mr. Conkling in just twenty-eight working hours sent over this wire to his paper bv the Morse system and using the Phillips code a total of 73,000 words, an average of 2,607.14 an hour, or 43.45 words a minute.

Much of this matter was sent from a seat in front of the speakers' stand in the convention hall while pandemonium was being raised.

The wire worked by Mr. Conkling was a duplex circuit. It really was four wires joined together by the Western Union company for this emergency. It ran from Denver to Kansas City, thence to St. Louis, thence to Pittsburg and thence to New York.

It is impossible to transmit over such a distance without the aid of repeaters, or automatic relays. These were at Kansas City, St. Louis and Pittsburg.

At each of these men were stationed at the direction of Mr. Conkling to "refine" the wire, as the operators say. Their duty was to keep readjusting the repeaters and make sure that the circuit was just right in spite of weather conditions and other things.

To send an average of 2,600 words an hour it is absolutely necessary that every letter should be distinct, otherwise the man receiving will have to break in and have it repeated. The man at the receiving end of the wire from Denver, H. R. Clark, did not break in on Mr. Conkling once in three hours, a record in itself.

In the long session of Thursday night, at which Mr. Bryan was nominated at 3.45 A. M., Denver time, words were flashed from Denver right into the New York office at the rate of fifty-two a minute and were taken by Mr. Clark on a typewriter without a break, the ticks of the instrument in the office being as distinct as if the wire ran to Harlem instead of to the Rockies. Besides being a record for speed it was also one for endurance.

On July 7, the first day of the convention, Mr. Conkling sent 14,750 words in five hours and twenty-three minutes, an average of 2,789 words an hour. On July 8 he increased the average to 2,949 words an hour, sending 8,100 words in two hours and forty-five minutes, and on the day following the record was 5,750 words in one hour and fifty minutes, or 3,136 words an hour.

The last day of the convention Mr. Conkling sent 10,370 words in three hours and twenty minutes, or 3,111 words in an hour, which was only a shade under his record of the previous day.

Not only is this put down as a record as long-distance work goes, but there is nothing in the archives to show that it has ever been done over short lines.

Mr. Conkling, in 1903, won a silver loving cup as the most perfect sender with a Morse key.

Mr. Clark, some years ago, received and wrote on a typewriter a president's message containing 22,000 words in ten hours without misplacing a single letter or "breaking in" on the sending operator.

Electrical Engineering in the Backwoods.

To the Editor of the Electrical Review:

"We were sitting around the stove in the bar of a little hotel in a Maine town," said an electrical salesman, "when the electric lights flickered and went out.

"From the darkness came a solemn voice that said:

"'Electric lights all out, b'gosh, and yet it ain't blowin' hard either. Something's happened to the dynamo, maybe.'

"I had been selling electrical supplies to the little lighting companies for several months but I had never heard this particular idea expressed before.

"I laughed long and loud, and was all the more amused when no one joined me.

"After they had lighted a big kerosene lamp, I proceeded to explain to the crowd that incandescent lamps can't be blown out by the wind. When I had finished, the old rube who had commented on the lights said:

"'Look here, young man, if you knew a little somethin' about local conditions and about your own business, you'd know that the wires in this township are hung up slack on the poles in some places and that they get to slatting in a good stiff breeze. When they do, there's a short-circuit that puts the line out of business.'"

R. G.

Regulate Stocks Now.

To the Editor of the Electrical Review:

The men who have their fingers on the pulse of our commercial life, and whose statistics measure the beats of the great arteries of business, are advising us that conditions are improving; the pulse is quickening, and a normal tone is becoming more of a surety.

This is as it should be. We have had time to adjust business to a great degree to the conditions brought upon us by the calamities of a few months ago. Manufacturers have curtailed their orders for raw material, and also their output, and have used up surplus stocks they had on hand. Wholesalers and jobbers have likewise reduced their stocks to the minimum, and so down the line from mine to finished product, from raw material to consumer, the closest scrutiny has been exercised to prevent congestion and loss.

Manufacturers, dealers and consumers of electrical machinery and supplies were among the first to be affected by the tidal wave of disaster, and they have made strenuous efforts to adjust themselves to the new conditions imposed.

Now that a more healthy tone is evident, it is the part of wisdom for the electrical manufacturer and dealer to foresee the conditions and meet them as they appear. Unless this is done, there will be greater difficulty than has been heretofore experienced in meeting the demands of consumers.

We have climbed the hill of prosperity and know how inadequate has been the ability of our jobbers, wholesalers and manufacturers to supply promptly the contractor, the central station and the public with the material they required; and when such material was obtainable, such was the congestion on the lines of transportation that long delays were the rule.

Now is the time when every dealer of apparatus and supplies should look over his stock and figure his probable requirements; and then order all he can safely handle. This will assist the manufacturer in his estimates of what he is likely to require in the matter of raw material and skilled labor in order to produce the finished product. Every item that can be safely ordered now will assist just that much in overcoming the difficulties that are sure to come on us both in production and transportation if orders are held up until material must be used. Prices now are right, and advantage should be taken of them and of the general conditions. To do this is to "take time by the forelock."

Chicago, Ill., August 1.

BOOK REVIEWS.

"How to Become a Competent Motorman." V. B. Livermore and J. R. Williams. New York. D. Van Nostrand Company. Cloth. 248 pages. Illustrated. 5 by 6½ inches. Furnished by the ELECTRICAL REVIEW for $1.

The authors of this book have endeavored to prepare a guide for the motorman which, without confusing his mind with undigested scientific principles, will explain to him the use of the different devices which go to make up the equipment of the modern electric vehicle. The different types of controllers are described and the effect of each movement of the controller handle is explained. Wiring diagrams are given for these systems. The troubles likely to happen to the different parts of the equipment are explained, the symptoms of each being pointed out and advice suitable for each emergency is given. The concluding portion of the hand-book deals with the different air-brake systems and tells how they should be taken care of. There is also a short chapter dealing with signals and signaling.

"Dynamo-electric Machinery." Francis B. Crocker. Chicago. American School of Correspondence. Cloth. 236 pages. Illustrated. 6½ by 9½ inches. Furnished by the ELECTRICAL REVIEW for $1.50.

This is one of the series of practical working guides which is being brought out by the American School of Correspondence. The object of the book is to give a simple and at the same time authoritative discussion of the theory, construction and design of dynamo-electric machinery. The general arrangement of the subject is that usually found in such books. The elementary theory of electromagnetic induction is first explained and it is shown how this is applied in the production of the electromotive force in the dynamo. The reactions produced by the load on the dynamo are then explained and the means adopted to minimize them are described. Part two deals with the characteristics of dynamos of different types and shows how these may be predetermined. The calculation of the magnetic circuit is taken up, followed by a discussion of methods of winding and some useful hints for the mechanical design are given. Part three deals with the construction of continuous-current machines and describes in some detail the different types of designs which have been found successful. In this section some tables of dimensions and speeds, which should be useful to designers, are given. The problem of treating in a satisfactory way the whole subject of continuous-current machines without writing a large book is not easy, but Professor Crocker has solved it here very successfully, his plan being to dwell upon the essential features, and pass over those not so important.

"Telephone Law." A. H. McMillan. New York. McGraw Publishing Company. Cloth. 332 pages. 6 by 8½ inches. Furnished by the ELECTRICAL REVIEW for $3.

The object the author of this book had in mind was to place in compact and concise form such legal information as would be of value to the practical telephone man. The book was not intended for practising lawyers. For this reason it is not exhaustive. A good deal of matter presented is of local interest, as must necessarily be the case where there are so many state governments; and it is, of course, impossible to cover every phase of this complex subject. However, what is here given will be of considerable assistance to the telephone man.

"Notes on Hydroelectric Developments." Preston Player. New York. McGraw Publishing Company. Cloth. 68 pages. 3 diagrams. 5 by 7½ inches. Furnished by the ELECTRICAL REVIEW for $1.

This little treatise has been prepared to assist investors in reaching a reliable understanding of the possibilities of any proposed hydroelectric development. The author purposely avoids discussing the engineering features of such developments, and refers to them only so far as is necessary to give a clear understanding of the power that can be obtained at any site and of the possible means of producing it. In Chapter i he gives a list of matters which should first be looked into. These include the general physical conditions of the site, records of past floods, and the possible markets for power. In Chapter ii a method of procedure for obtaining this information is suggested. In Chapter iii he explains the kind of engineering examination that should be made. In Chapter iv the market for power is considered, with the possible competitors of the power plant. Chapters v and vi deal with the cost of producing energy, and central station economics; Chapter viii with the sale of energy; Chapter ix takes up the problem of producing secondary power, and the concluding chapter of the book deals with the effect of capital cost upon the selling price of energy. The book seems to be admirably adapted to its purpose, as a technical education is not necessary to follow the argument. It should enable any business man to reach a satisfactory conclusion respecting the value of any power site, provided, of course, he follows the plan here laid out.

To Reorganize Virginia Traction Companies.

The reorganization of the Virginia Passenger and Power Company, the Richmond Passenger and Power Company, the Richmond Traction Company and controlled lines has been undertaken by a committee consisting of Douglas Robinson, of New York, chairman; Frank J. Gould, of New York; Charles S. Whelan, of New York; Percy M. Chandler, Philadelphia; R. Lancaster Williams, of Baltimore, and Fritz Sitterding, of Richmond, Va., with John D. Dickinson, Jr., secretary, and Henry W. Anderson, counsel, and Carter, Ledyard & Milburn, consulting counsel.

The committee has prepared a plan of reorganization which has been deposited with the Bowling Green Trust Company as depositary and requests the holders of the various securities affected by the reorganization to obtain the same and deposit their securities under it before September 3. The protective committee of the Richmond Passenger and Power Company consolidated bondholders and a similar protective committee representing the South Side Railway and Development Company's bondholders have endorsed the plan of reorganization.

Examination for Inspector of Mechanical and Electrical Engineering.

The United States Civil Service Commission announces an examination on September 2 and 3 to secure eligibles from which to make certification to fill a vacancy in the position of inspector of mechanical and electrical engineering, at $2,190 per annum, in the office of the supervising architect, Treasury Department, and vacancies as they may occur in any branch of the service requiring similar qualifications. The duties of the specific position consist of inspecting and testing mechanical and electrical equipment entering into the modern government or office building, requiring high-class education and extensive experience in all branches of enginering embracing this class of work. Applicants should apply at once to the United States Civil Service Commission, Washington, D. C., for application form 1,312. No application will be accepted unless filed with the commission in complete form prior to the hour of closing business on Saturday, August 22. In applying for this examination the exact title as given in the heading of this announcement should be used.

"A.C." ACCUMULATOR SUBSTATIONS; AND THE USE OF ACCUMULATORS FOR PEAK LOADS.[1]

BY A. M. TAYLOR.

Many causes have conspired to delay the introduction of accumulators into central stations in this country for the purpose of supplying energy for light and power during the time of peak load.

The non-fulfilment of the great expectations raised some twenty years ago has had its reaction, and numerous failures in actual practice have caused central station engineers to lose confidence in all cells of every make for light and power supply as a substitute for generating plant.

Even when one succeeds in convincing an engineer that a battery will pay for itself if it only lasts as short a period as, say, five years, and that, therefore, there can not be much risk in installing it (as guarantees for much longer periods of maintenance can be had, at reasonable rates, and from responsible parties), the said engineer will hesitate to put it in directly it is brought home to him that, in order to insure its paying under these conditions, it must be relied on as a real, and not merely a nominal, substitute for generating plant.

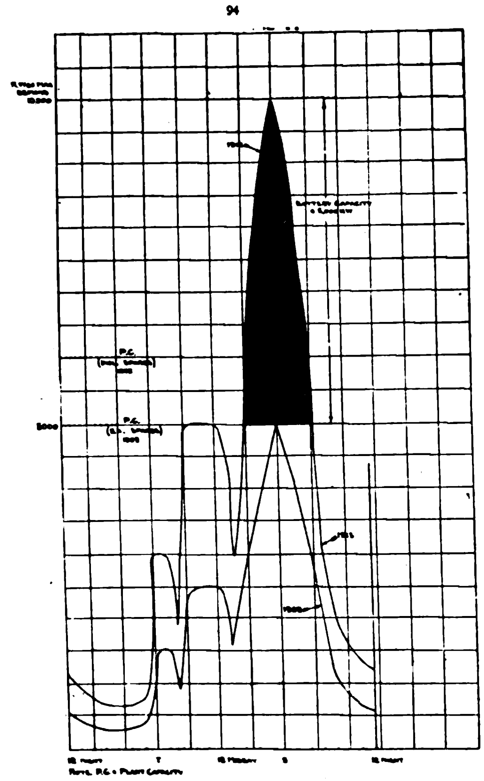

FIG. 1.—TYPICAL LOAD CURVE FOR STATION HAVING PRESENT MAXIMUM DEMAND OF 5,000 KILOWATTS. FURTHER EXTENSIONS ARE ASSUMED TO BE CARRIED OUT WITH BATTERIES.

ENERGY LOSSES.

It requires to be realized by engineers that, if cells are installed exclusively to take the peak of the load, and are not discharged unnecessarily, the value of the energy wasted in the cells and accessories is only of the order of one to two per cent of the value of the revenue introduced by said cells. Consequently their inefficiency is not nearly so serious a matter as most people imagine.

Consider Fig. 1, the lower half of which shows a typical load-curve for a station having a present maximum demand of 5,000 kilowatts. All further extensions are assumed to be carried out with batteries until, in 1913, the maximum demand reaches 10,000 kilowatts.

Neglecting changes in the load-factor, we may assume that, say, 5,000,000 units are sent out in 1908, and 10,000,000 units in 1913. The battery has thus introduced a revenue of, say, $156,000 per annum (taking three cents as an all-round price for light and power and neglecting losses in transmission in each case). What are the losses due to the inefficiency of the battery and adjuncts?

The lower curve in Fig. 2 has been compiled from figures published for the maximum demands at Neptune Bank by Merz and McLellan in April, 1904, as a rough approximation to the relative periods of time which the station was working during the year on different loads.

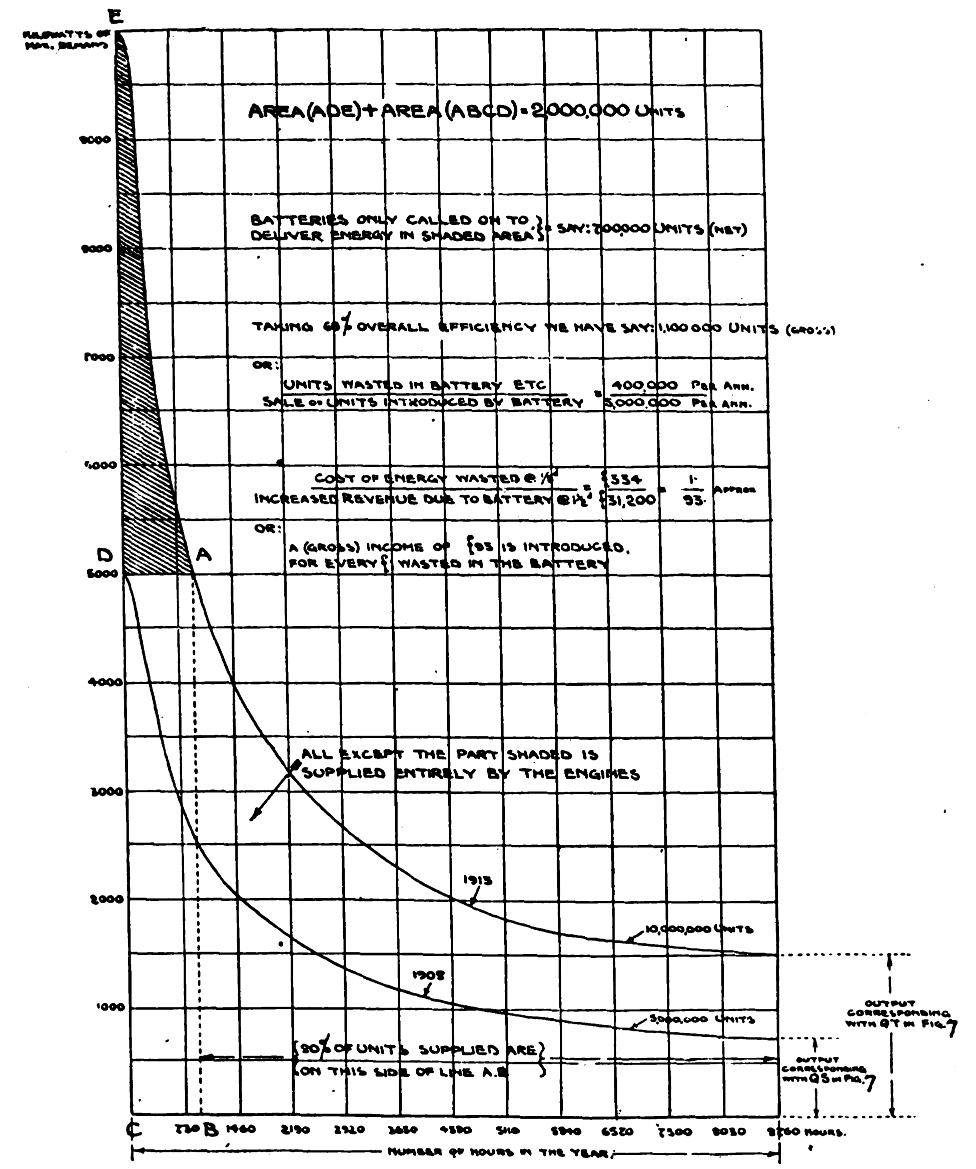

FIG. 2.—ANALYSIS OF PROPORTION OF WORK CARRIED BY ENGINE AND BATTERIES.

Referring to the upper curve of Fig. 2, which embraces the extra 5,000,000 units "introduced" by the battery, it will be noticed that the batteries are only called upon to deliver energy when the peak exceeds 5,000 kilowatts. They are, of course, charged when the load is small and the engines and boilers inefficiently loaded.

To simplify the question, the author, in the notes accompanying Fig. 2, has

[1] Abstract of a paper read before the Incorporated Municipal Electrical Association, Nottingham (England), June 30 to July 3

only considered the employment of the battery in the winter, and for discharging at the heaviest peaks; the extra losses involved in the occasional charges and discharges required during the summer are not serious.

lowed. The cost of 400,000 units at two-fifths cent (or $1,600) is, then, the sum which we must set off against the revenue of $156,000, introduced by the cells, on account of the "wasted" units in the battery.

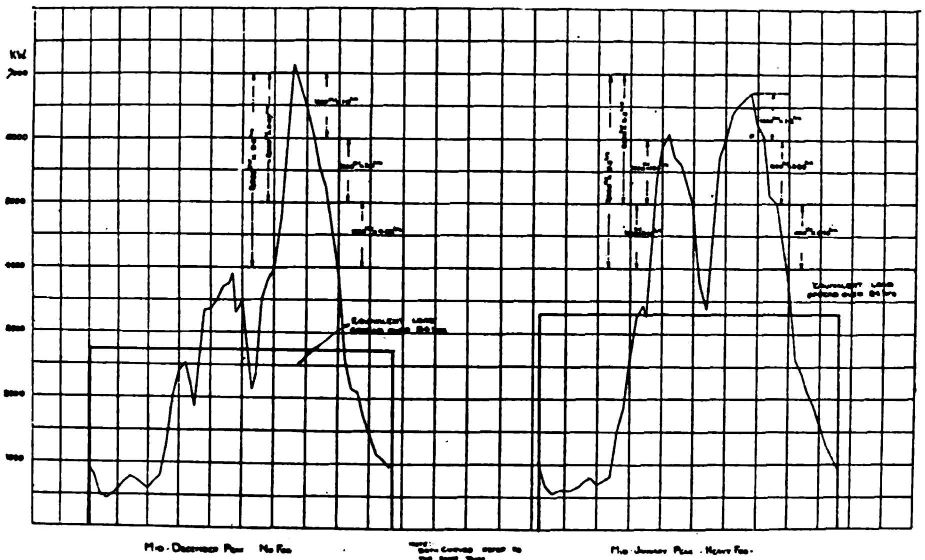

FIG. 3.—TYPICAL STATION LOAD CURVES, SHOWING DURATION AND EXTENT OF BATTERY DISCHARGE.

Referring to the notes accompanying Fig. 2, it will be noticed that some 1,100,000 units are put into the battery; of which some 700,000 are reclaimed as "useful" work. In the figures for the increment in fixed charges due to the introduction of the battery (considered later in discussing Fig. 6), the author debits the "extra" units introduced by the battery with the whole of the increment in the fixed charges of the station, as well as with the capital charges on account of the cells; consequently it is unnecessary to debit the 400,000 "wasted" units with anything beyond the coal, water and petty stores consumed. These items are sufficiently covered by the two-fifths cent allowed.

PROPORTION OF PEAK TAKEN UP.

The capital cost of the cells depends, of course, very largely on the proportion of the peak which is taken up by them, each successive kilowatt so taken up requiring a longer period of discharge. This will be evident from Fig. 3, the left-hand diagram of which shows the peak load of a station in a large industrial town, and may be taken as a typical case. Referring to this figure it will be noticed that the first thousand kilowatts taken up require only an average duration of discharge of 1.15 hours, the second thousand kilowatts require three hours, and the third thousand kilowatts 4.26 hours. The average duration of discharge for 3,000 kilowatts taken up is as shown, 2.8 hours, and for 2,000 kilowatts it is 2.07 hours.

On the right-hand side of Fig. 3 is given a peak load-curve for the same station during an exceedingly heavy fog, and the corresponding hours of duration for each successive thousand kilowatts on either of the two humps of this peak are given in horizontal figures, the equivalent hours of duration for the joint load of the two peaks being given in vertical figures; the notes at the top of the figure show the capital cost, per kilowatt of maximum demand taken up by the cells, for different proportions of the peak, both for the left-hand and for the right-hand diagrams. It will be noted that the cost for taking up $\frac{2000}{7000}$ of the peak in the right-hand diagram is very little in excess of that of taking up $\frac{3000}{7000}$ of the peak in the left-hand diagram.

In the comparison which will now be made between the cost of generating plant and batteries, it is assumed that no provision is made for dealing with fog loads, there being numerous towns in the country where such loads are not materially felt. Even where the contrary is the case, the battery can still hold its own, provided that a lesser proportion of the peak is taken up.

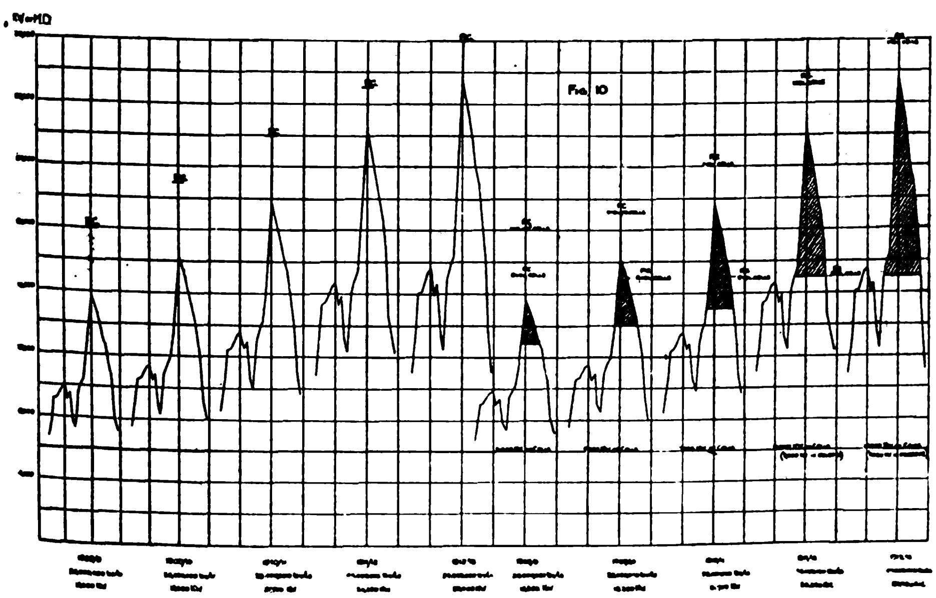

FIG. 4.—ASSUMED ANNUAL DEVELOPMENT OF STATION PEAK LOAD COMPARED WITH SAME DEVELOPMENT ASSISTED BY STORAGE-BATTERY INSTALLATION.

CELLS v. GENERATING PLANT.

In order to obtain a clear idea of the various economies, both in capital cost and running expenses, which may be effected by the introduction of cells to take the peak of the load for light and power work, a typical station has been selected, in which the annual development is assumed to progress at a healthy rate, and the effect is noted of installing accumulators to deal with the peak of the load in place of generating plant, and the annual expenses are estimated in the two cases over a number of years.

On the left-hand side of Fig. 4 is shown the assumed annual development of the peak of the load for a large steam-power station, and the plant capacity allowed (including spares) to meet same.

On the right-hand side of Fig. 4 is similarly shown the same station carried over the same term of years by means of cells added to the existing generating plant, no further generating plant being put down. In both cases only sufficient spare plant has been allowed to cover the chance of a breakdown of one of the generating units. This may be criticized as insufficient, but owing to the large capacity of the battery for short-period discharges, the comparison would undoubtedly show still more favorably to the latter if a larger margin of spare-plant capacity were allowed. In Fig. 5 is given the estimated figures for the development of a steam station whose demands are shown by Fig. 4, no battery being considered, and in Fig. 6, the corresponding expenses, with the accumulators considered in Fig. 4 are similarly expressed. It will be noted in the latter figure (6) that the steam expenses incurred in the year 1907-8 are taken as the basis, and it is assumed that since no further generating plant is added, the fixed charges, and interest and sinking fund charges, will remain constant.

To the total of the steam-plant charges incurred in the year 1907-8 is added a sum representing twelve per cent on the cost of the cells added during the year 1908, and the total so obtained is plotted as the cost for the year ending in March, 1909. The capital cost of the cells and their accessories inclusive of building has been put in at £15 ($75) per kilowatt throughout. In the years 1910 to 1911, 1911 to 1912 and 1912 to 1913, a small sum (£1,000) has been added to cover the cost of extra wages for attending to the cells and apparatus.

With reference to the twelve per cent taken on the cost of the cells in the above figures, it may be explained that interest charges on the cells are taken at three per cent and depreciation and maintenance charges at nine per cent.

It will be noted that in Fig. 6 the savings introduced by the cells, as against steam plant, are £12,000 ($60,000), £24,000 ($120,000), £37,000 ($185,000), £46,000 ($230,000) and £64,000 ($320,000), respectively, in the five years following 1907-8; a total saving of £183,000 ($915,000).

Taking the increments which each year show over 1907-8 in annual expense, and dividing these by the corresponding increments in units sold, shows that for the steam plant the costs of each extra unit sold are 2.18 cents, 1.8 cents, 1.82 cents, 1.72 cents and 1.70 cents, whereas with the combined steam and accumulator plant the corresponding costs are found to be 1.24 cents, 0.88 cent, 0.8 cent, 0.84 cent and 0.78 cent, with the result as already stated that the total net saving in five years is $915,000 after providing for the payment of interest, depreciation and maintenance on the accumulators, representing an average saving of $183,000 per annum.

It may be pointed out that the £64,000 ($320,000) saving in 1912-13, would pay an additional ten and one-half per cent interest on the total investment in cells and accessories, including that of 1912-13.

As a further illustration of the relative costs of the cells and of the steam plant, the author has resolved the cost into curves, connecting load-factor and price per unit, which are shown in Fig. 7. In this figure the cost for the battery itself and the increment in fixed charges introduced by it is shown by the curve AB, the corresponding curve for the increment in the generating plant (excluding distribution) being marked CD on the above figure. It is to be noted that in these two curves (Fig. 7), we have a comparison between the cost of introducing to an already large generating station the necessary steam plant, of the most modern reciprocating type and in large units, in order to deal with a stated increment in the maximum demand of the station; and on the other hand, the corresponding costs for accumulator plant capable of dealing with the same increment in the maximum demand. We are not, therefore, comparing merely the total capital and other costs per kilowatt, incurred to date (which figure would be handicapped by the amount of capital that had been spent in past years on obsolete or inefficient plant), but are considering the relative merits of the two systems under absolutely identical conditions. To show the difference that would be obtained in favor of the electric accumulator system, were we to compare its added costs with the existing costs of the steam system (as we might do if the station had reached its limit of exten-

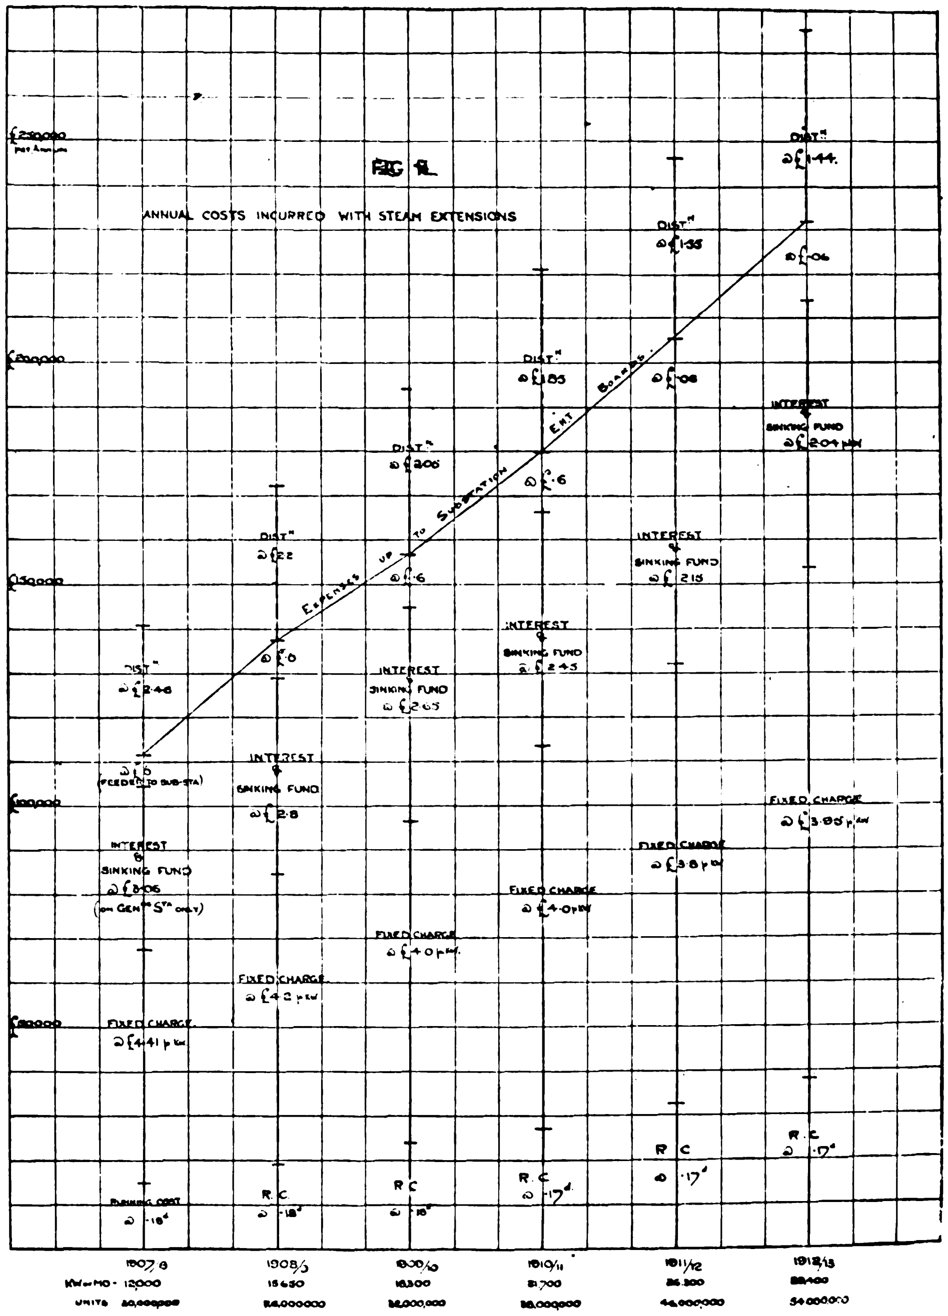

Fig. 5.—Estimated Figures for Development of Steam Station, No Battery Being Considered.

sion), we have only to compare curve AB with curve EF (the latter representing the costs for 1907-8, for any load-factor, as deduced from the ordinate plotted for a particular load-factor in Fig. 5). The author submits that in estimating the saving introduced by putting down accumulators, it is not in certain cases unfair to take the difference in costs between the curves EF and AB as representing the saving, since the station is at the present time charging the consumer on the basis of the curve EF, while the added cost for each unit sold with the accumulators is only that represented by the curve AB.

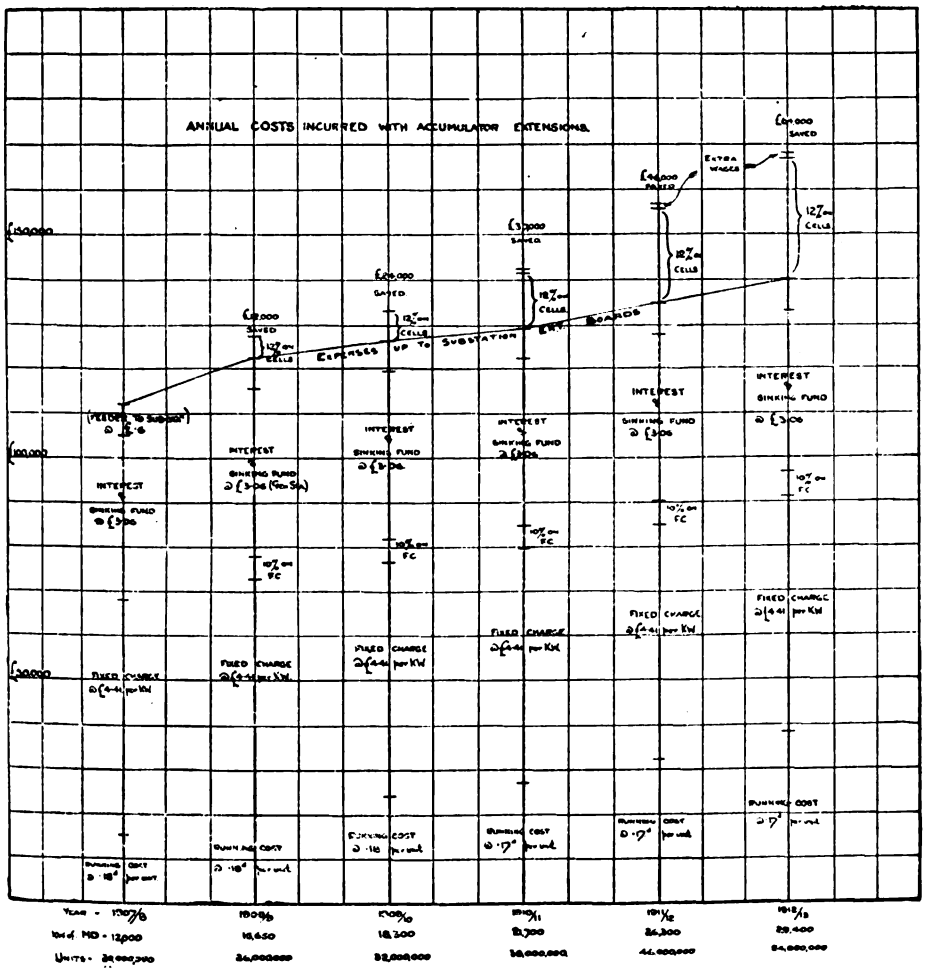

Fig. 6.—Estimated Figures for Development of Steam Station, with Storage Battery Considered.

Each extra unit sold (due to the growth of the load) would therefore bring in, if present prices remained unaltered, a net profit represented by the difference between these two curves; or say 1.9 cents per unit on a sixteen per cent load-factor.

ALTERNATING-CURRENT SUBSTATIONS.

The author trusts that, in the examination of the energy losses incurred by the accumulator system it will be conceded that the cost of the energy used in charging the cells is so very low that the inefficiency of the cells and accessories is much more than compensated by the gain in coal economy on the "interest-paying" units. The result of calculations which he has made in conjunction with the employment of substations has satisfied him that there is a future for such a scheme, (particularly in connection with long-distance transmission of power), the batteries being put down here, rather than at the generating station.

The limits of the present paper do not allow of going into details but, from inquiries made of accumulator companies, it is found that, where cells of very large individual capacity can be installed, it is possible to obtain a discharge representing six kilowatts (on a three-hour basis) for every square yard of floor space, for a single tier of batteries; and where there are two tiers this would be raised to twelve kilowatts, or if three tiers, eighteen kilowatts per square yard of ground space. These figures do not include any space for the rotary converters, or the boosters or auxiliary apparatus; but where the units are of moderate size, the extra floor space required for these is not at all serious. Assuming for the moment that a separate building were erected for the cells, of a cheap construction, it would be quite possible to erect such a building, where the cells were on a single floor only, for something under $1.87 per kilowatt, and even where the cells were arranged on two floors, or even three floors, the cost of such a building need not exceed, say, $3.75 to $5 per kilowatt, and, of course, the cost of maintenance of such a building is trifling compared with that of the cells.

As regards the cost of land, this, in the vicinity of substations, could, generally speaking, be obtained at a rate not materially in excess of $3 per square yard, which, for a single-story battery, works out at fifty cents per kilowatt, which is really quite negligible compared with the cost of the battery. It is, however, of course, often a matter of the greatest difficulty to get the land just where it is required, and hence it is highly desirable to adopt any means whereby the floor space required for the accumulators can be greatly reduced. In the smaller sizes of substations, such as would be employed for prospecting purposes, and in fact up to 2,000 kilowatts, the author believes that his low-voltage system of accumulators will be found very useful in reducing floor space (as well as capital cost), and he has taken advantage of the facilities which the employment of alternating currents offers for stepping down the voltage to produce a scheme which is at once cheap, flexible and easily extensible with the growth of the load in the substation. By this means it is possible to use the batteries to deliver alternating current of high pressure into the line at times of peak load, while at the same time delivering direct current of suitable pressure to the bus-bars of the substation, and the author believes that this and other combinations will be found to be valuable as a means of relieving the main generating station at the time of peak load, as well as the feeders. The efficiency to be obtained on discharge, as between battery terminals and extra high-tension alternating-current bus-bars, will, in a large substation, be found to be of the order of ninety-three per cent, and that between the battery and the substation direct-current bus-bars of the order of eighty-seven per cent, and even in a small substation these figures would not be materially less than ninety per cent and eighty-two per cent, respectively. It is further suggested that such a system may be found very helpful on long high-pressure lines, such as those on the outskirts of a power company, the accumulator in this case enabling a given amount of maximum demand to be met at a subcentre for a very much less expenditure in extra high-tension cables than would otherwise be incurred; or, to put it in another form, it would be possible to supply a given maximum demand at much greater distances from the main generating station with economy than has hitherto been the case. Indeed, if the savings introduced in the generating plant by the adoption, in this way, of accumulators at the substations were utilized for the purpose of extending the lengths of the extra high-tension feeders, it might be possible to carry the transmission several times as far as is now considered practicable, without incurring any greater charges than would

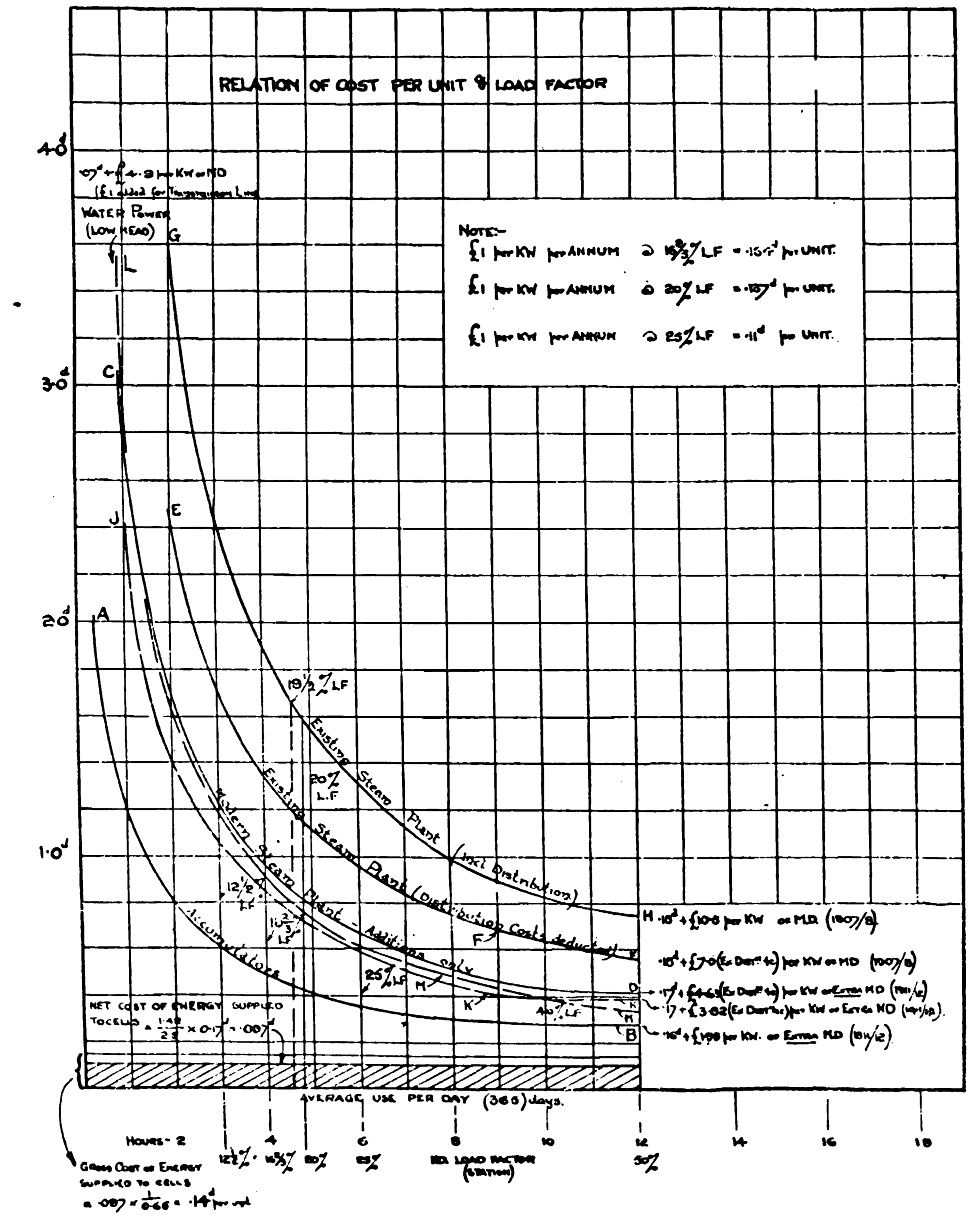

FIG. 7.—NET EFFECT OF USING CELLS ON THE COST OF EXTRA UNITS AND STATION LOAD FACTOR.

be incurred by the continuance of the use of steam plant for extensions, coupled with the employment of the shorter feeders.

CONCLUSIONS.

In the present paper the author's investigations have been confined to the consideration of the introduction of cells in connection with a large modern station, with ample station and street accommodation for extensions in all feeders to substations, and on the further assumption that there is land adjoining the station to accommodate additional steam plant. Where any, or all, of these facilities do not exist, especially if the limit of the station development has been reached, there is a strong case for accumulators.

By their means it is quite possible to postpone the erection of a new station for some years and thus to obtain the advantage of the latest and best experience in the selection and performance of plant.

As regards the introduction of accumulators into the smaller stations, the author ventures to express the opinion that the causes of high coal consumption in these stations are due, not altogether to the smallness of the engine and boiler units, or even to their being of somewhat obsolete type, but rather to the greater proportion which the stand-by losses and the fixed charges bear to the total cost of operation. The use of cells would introduce great economies here; and in many cases would enable the existing small units to be replaced by large and more economical units with the certainty of being able to find a suitable load for the latter, even where the load-factor of the station happens to be a poor one; thus avoiding, in many cases, the immediate building of a new station.

The author suggests that Fig. 7 will be found helpful as showing at a glance and in a single diagram the net effects of using cells on the cost per (extra) unit for different (station) load-factors. It also shows in a clear way the pronounced saving introduced by using cells, as against modern steam plant; and that, too, of the largest sizes likely to be available in the majority of cases.

The capital costs taken for the increment of steam plant (including building and land) range from $200 to $100 per kilowatt of plant capacity added. It may here be mentioned that in the costs plotted in Fig. 5 the cost of the feeders on the extensions to the substation where the battery is placed is also debited to the steam extensions, an allowance of $3 per kilowatt of maximum demand per annum being taken. In Fig. 7, however, this is reduced to $1.50 per kilowatt of maximum demand.

The figure of $75 per kilowatt of maximum demand for the batteries similarly includes building and land, but no spare battery capacity; there being 100 per cent overload capacity in the battery for one hour, and the chance of interruption with a properly designed battery plant being so much more remote than with running machinery, or even steam boilers and accessories.

As regards the transmission of power over long distances, such as from water-power centres, the author suggests that the facilities for increasing the radius of transmission (for a given limitation in electromotive force) which the storage system offers, combined with the great advantage of having the reserve of power at the point where it is wanted, should be considerations of moment in introducing cells for such work. There are many large water-power transmissions on which he believes it will be found that the curves connecting load-factor and cost per unit will consist of a much smaller element of "running cost" and an equally large, or larger, element of "fixed charges" than in the steam station shown in Fig. 7 (especially when transmission line costs are included), and on all such there should be an excellent opening for alternating-current substations.

Coal-Mining Reports.

According to the figures prepared by the United States Geological Survey, in 1907 Ohio produced 32,142,419 short tons of coal, having a spot value of $35,324,746. Early in 1908 George Harrison, chief inspector of mines for Ohio, estimated that the total production of the state in 1907 had been about 30,000,000 tons, which would have been equivalent to an increase of somewhat less than ten per cent over the output of 1906. The complete statistics for 1907, which will soon be published by the United States Geological Survey, show that Mr. Harrison's estimate was conservative, as the actual increase in production was more than 2,000,000 short tons in excess of his estimate. The production for the year showed an increase of 4,410,779 short tons, or 15.91 per cent, in quantity and of $4,978,166, or 16.4 per cent, in value over that of 1906. In 1907 the coal-mining industry in Ohio was not greatly affected by labor troubles or strikes, the car supply was more nearly adequate than in some other states, and the average prices were satisfactory to the operators.

The total production of coal in Oklahoma in 1907 was 3,642,658 short tons, having a spot value of $7,433,914, according to the Geological Survey's annual report on mineral resources of the United States for 1907.

Since the Survey's report for 1906 was published the area included within the territory of Oklahoma and the Indian Territory has been organized and admitted into the Union as the state of Oklahoma. As, however, the entire coal-producing district is included in what was Indian Territory, the production of the state of Oklahoma is co-ordinate with the production of Indian Territory.

The new state began its history of coal production with a noteworthy increase over that of Indian Territory in 1906, when the output amounted to 2,860,200 short tons, valued at $5,482,366. Compared with this the production of 1907 showed an increase of 782,458 tons, or 27.36 per cent, in quantity, and of $1,951,548, or 35.6 per cent, in value. Only three states exceeded Oklahoma in percentage of increase in 1907 over 1906. These were Michigan, whose production increased fifty-one per cent; Arkansas, which had an increase of 43.3 per cent, and New Mexico, with an increase of 33.8 per cent.

The total production of coal in Oregon in 1907 was 70,981 short tons, having a spot value of $166,304.

The Coos Bay field is the only productive coal field in Oregon. It is situated in the southwestern part of the state, in Coos County, and occupies a total area of about 250 square miles, its length north and south being about thirty miles and its maximum breadth at the middle about eleven miles. Among the other coal fields that have been prospected in the state are the Upper Nehalem field, in Columbia County; the Lower Nehalem field, in Clatsop and Tillamook counties; the Yaquina field, in Lincoln County; the Eckley and Shasta Costa fields, in Curry County; the Eden field, in Coos County, and the Rogue River Valley field, in Jackson County—all west of the Cascade Range. None of these fields has been developed to the point of production. Another field lies in the basin of John Day River, east of the Cascade Range, but little is known concerning it. All the fields west of the range, except the Coos Bay, are of rather small area, the largest being the Upper Nehalem, which has an area of less than twenty square miles. The coal of all these fields is lignitic. Its transportation is confined exclusively to Coos Bay and the Pacific Ocean, and San Francisco is the principal market. The Coos Bay field is divided by its structure into six portions—four basins and two arches. The basins are known as the Newport, the Beaver Slough, the Coquille, and the South Slough, and are separated by the Westport and Pulaski arches.

The output of the Tennessee coal mines in 1907 amounted to 6,810,243 short tons, having a spot value of $8,490,334, showing an increase of 550,968 short tons, or 8.8 per cent in quantity, and of $822,919, or 10.73 per cent, in value, over the production in 1906. The average price per ton advanced from $1.22 in 1906 to $1.25 in 1907. About forty per cent of the output of the Tennessee mines is used for railroad fuel, 15 per cent is taken by the comparatively restricted local market of the eastern part of the state, and the rest of the product is marketed in competition with coals from Alabama and southern Kentucky. That the industry did not show greater gain in 1907 was due in part to the exceptionally mild weather in November and December, which caused decrease in the demand for coal for domestic purposes, and in part to added competition from many of the large mines in Virginia, Alabama, West Virginia and Tennessee, forced by the condition of the iron industry to market for steam coal much of their product that would otherwise have been coked. Notwithstanding these adverse conditions, however, the output of the state was the largest ever recorded.

The production of coal in Texas in 1907 was greater by 25.53 per cent, in quantity, and 27.53 per cent, in value, than that of 1906, according to E. W. Parker, of the United States Geological Survey, amounting to 1,648,069 short tons, having a spot value of $2,778,811.

This increase in the coal output is largely the result of the condition of the petroleum industry in the state in the last two years. In 1906 the output of petroleum was sixty per cent less than in 1905 and the coal output showed an increase of 112,189 short tons. In 1907 the production of petroleum was about the same as in 1906, the decrease being insignificant, but the advance in the price of fuel oil in the state was so decided that a number of railroads returned to coal for locomotive use, and the effect on the coal industry is shown by the figures given above.

Coal or lignite was produced in sixteen counties of Texas in 1907, or three more than in 1906. The counties reporting production of bituminous coal—Erath, McCullough, Maverick, Palo Pinto, Parker, Webb and Wise—were the same as in 1906; of the lignite-producing counties—Bastrop, Fayette, Hopkins, Houston, Leon, Medina, Milam, Robertson and Wood—three (Fayette, Lyon and Robertson) were new.

The bituminous and lignite mines in these counties gave employment to 4,227 men in 1907 for an average of 242 days, as compared with 3,048 men for an average of 227 days in 1906. Of the total number, 3,137 men were employed in the bituminous mines for an average of 255 days, and 1,090 in the lignite mines for an average of 204 days. The average production per man per day in the bituminous mines was 1.18 tons, and in the lignite mines 3.18 tons. The average production per man for the year was 300 tons in the bituminous mines and 649.3 in the lignite mines, the average for the state being 390 tons. In most of the bituminous mines the men worked eight hours a day, but in the lignite mines the ten-hour day is the rule. One mine employing sixty men reported nine hours as the length of the working day. Mining machines were used in three mines in 1907, and the product amounted to 36,100 short tons mined with thirteen machines; in 1906 the use of twelve machines resulted in 22,682 short tons of coal.

The total production of coal in Idaho in 1907 was 6,508 short tons, having a spot value of $26,494. Lignite beds occur in several areas in Idaho, but little mining has been done until within the last five or six years. The producing districts are the Horseshoe Bend and the Jerusalem, occupying the lower portion of a ridge between Boisé and Payette Rivers; an area near Salmon City, in Lemhi County, and one at the eastern edge of the state, in Bingham and Fremont counties, where the Sublette field of Wyoming extends across the state line. The principal production in 1905 and 1906 was in the Salmon district, in Lemhi County, 4,380 tons having been mined there in 1905, and 4,285 tons out of a total of 5,365 in 1906. In 1907 Fremont County was credited with a production of 2,884 tons and 3,500 tons were produced in Lemhi County. Bingham County also produced a small quantity of coal in 1907.

The total production in the state in 1907 showed an increase of 1,143 tons, or 21.3 per cent, in quantity and of $7,956, or 42.92 per cent, in value.

Reception to Farman by the Aero Club.

The Aero Club of America tendered a reception to Henry Farman, the French aeronaut, on the evening of July 30, at the Hotel Astor, New York city. Madame Farman and Mrs. Paul LaCroix received, and the guests were introduced to Mr. Farman by Augustus C. Post. Charles Jerome Edwards welcomed the guest of honor in a speech in which he told of the interest of Americans in Mr. Farman's aeroplane flights. Addresses were also made by several others eminent in aeronautics, the closing address being delivered by Charles J. Glidden, who is widely known in the electrical field and who is an enthusiastic automobilist and aeronaut.

Mr. Farman made a short address, expressing his pleasure at meeting with his brother aeronauts and so many men prominent in social and engineering life, and stated that he had complete confidence that the dirigible aeroplane was a certainty.

One of the interesting features of the evening was the brief address made by Homer W. Hedge, who talked very enthusiastically of the possibilities of the dirigible balloon and explained the formation of the Aero Club of America.

There were a great many electrical men present at this gathering, giving it the aspect of a meeting of one of the electrical engineering societies with which electrical men are so familiar.

Mr. Farman is scheduled to make a series of flights at the Brighton Beach Race Track, Brighton Beach, Brooklyn, N. Y., from August 1 to August 9.

FINANCIAL REPORTS OF ELECTRICAL COMPANIES.

MONTREAL STREET RAILWAY COMPANY.

The report of earnings of the Montreal Street Railway Company for the nine months ended June 30, 1908, shows that the company did not earn the seven and one-half per cent dividends paid by it during the period. The earnings report indicates that the company either will have to reduce its dividend from the two and one-half per cent quarterly rate during the last quarter of the year or else show a large amount paid out of profit and loss surplus for the year.

The earnings for the nine months ended June 30 show as follows: Gross, $2,672,763; expenses, $1,651,707; net, $1,021,056; charges, $150,876; surplus, $570,180.

During the company's fiscal year ended September 30, 1907, it earned 9.65 per cent on the total $9,000,000 capital stock then authorized. Since the beginning of the current year the authorized capital stock has been increased to $10,000,000. The bonded indebtedness has also been increased by $2,000,000.

UNITED RAILWAYS OF ST. LOUIS.

The gross earnings of the United Railways of St. Louis for the six months ended June 20, 1908, showed a decrease equal to 2.34 per cent, but decreases in expenses and charges brought about an increase equal to 9.39 per cent in net income. The earnings for the six months' period for 1908 are: Gross, $5,163,555; expenses, $3,367,509; net, $1,796,046; charges, $1,385,547; net income $410,499; preferred dividend, $124,580; balance, $14,081.

TOLEDO RAILWAYS AND LIGHT COMPANY.

The report of the Toledo Railways and Light Company for the month of June and six months ended June 30 shows June gross of $201,766; expenses, $107,458; June net, $94,308; other income, $8; total income, $94,316; charges and taxes, $71,762; June surplus, $22,554. Six months' gross, $1,230,375; expenses, $682,388; six months' net, $547,987; other income, $2,783; total income, $550,770; charges and taxes, $420,136; six months' surplus, $130,634.

SEATTLE ELECTRIC COMPANY.

The report of the Seattle Electric Company for the month of May and twelve months ended May 31 shows May gross of $386,961; expenses, $216,858; May net, $170,103; charges, taxes and sinking fund, $87,431; May surplus, $82,672. Twelve months' gross, $4,365,709; expenses, $2,593,833; twelve months' net, $1,771,876; charges, taxes and sinking fund, $1,001,398. Twelve months' surplus, $770,478, a decrease of $38,159 as compared with the same period a year ago.

NORFOLK & PORTSMOUTH TRACTION.

The report of the Norfolk & Portsmouth Traction Company for the month of June and six months ended June 30 shows June gross of $164,526; expenses, $98,622; June net, $65,904; six months' gross, $875,619; expenses, $574,535; six months' net, $328,084.

BOSTON & WORCESTER STREET RAILWAY.

The gross earnings of the Boston & Worcester Street Railway Company for June were $54,500, the largest in the current fiscal year, and 3.6 per cent larger than in the corresponding month a year ago. The gross earnings on the main line last month showed an increase of seven per cent, but the business on the branch lines, which is local in character and in mill towns, showed a decrease, compared with a year ago, owing to the industrial depression.

MICHIGAN STATE TELEPHONE COMPANY.

The Michigan State Telephone Company's report for the six months ended June 30 shows gross earnings of $1,648,984; expenses, $1,211,252; net earnings, $437,732; interest, $208,935; balance, $228,797; dividend on preferred stock (six per cent), $68,498; surplus, $160,299.

NASHVILLE RAILWAY AND LIGHT COMPANY.

The report of the Nashville Railway and Light Company, Nashville, Tenn., for the month of June and six months ended June 30 shows June gross of $130,994; expenses and taxes, $73,622; interest charges, $32,069; reserve and sinking fund, $3,921; surplus, $12,623. Six months' gross, $760,050; expenses and taxes, $464,183; interest charges, $188,061; reserve and emergency fund, $22,670; six months' surplus, $85,136.

AMERICAN LIGHT AND TRACTION COMPANY.

The report of the American Light and Traction Company for the six months ended June 30 shows net earnings of $2,499,257, an increase of $186,292, and a final surplus after allowing for dividends and reconstruction reserve of $538,853, an increase of $116,597. The total surplus now stands at $3,196,257.

MEMPHIS STREET RAILWAY COMPANY.

The Memphis Street Railway Company, of Memphis, Tenn., for the month of

June and six months ended June 30 shows June gross of $140,882; expenses and taxes, $87,092; interest charges, $34,876; reserve and emergency fund, $2,500; June net surplus, $16,414. Six months' gross, $775,067; expenses and taxes, $494,-401; interest charges, $208,439; reserve and emergency fund, $15,000; six months' net surplus, $57,227.

CUMBERLAND TELEPHONE AND TELEGRAPH.

The report of the Cumberland Telephone and Telegraph Company for the month of June and six months ended June 30 shows June gross, $504,364; expenses, $292,209; June net, $212,155; charges and taxes, $35,374; June surplus, $176,781. Six months' gross, $3,056,978; expenses, $1,782,208; six months' net, $1,-274,770; charges and taxes, $223,018; six months' surplus, $1,051,760.

AMERICAN TELEPHONE AND TELEGRAPH COMPANY.

The comparative statement of earnings and expenses of the American Telephone and Telegraph Company for the month of June and six months is as follows:

Month of June—

	1908.	1907.
Interest and other revenue	$815,351	$603,243
Telephone traffic (net)	326,237	283,161
Real estate	13,156	12,814
Other sources	40,296	42,399
Total	$1,195,040	$941,617
Expenses	203,590	181,974
Net earnings	$991,450	$759,643
Interest	647,540	579,346
Balance	$343,910	$180,297

January 1 to June 30—

	1908.	1907.
Dividends	$6,443,344	$5,685,089
Interest and other revenue	4,951,788	3,813,182
Telephone traffic (net)	1,995,864	1,832,114
Real estate	55,735	37,541
Other sources	341,658	200,845
Total earnings	$13,785,391	$11,568,772
Expenses	1,073,770	1,032,569
Net	$12,714,621	$10,536,203
Interest	3,871,675	3,439,791
Surplus	$8,842,945	$7,096,411
Dividends April-July	6,120,092	5,262,056
Net surplus	$2,722,853	$1,834,355

DENVER CITY TRAMWAY COMPANY.

A meeting of the stockholders of the Denver City Tramway will be held August 27 to authorize an issue of $25,000,000 five per cent thirty-year mortgage bonds, to be used for the following purposes: To refund the present outstanding indebtedness; to acquire all or any part of the property and assets of the Denver & Northwestern Railway Company and the Denver Tramway Power Company and to pay off or exchange for the outstanding bonds of these two companies, as well as to provide funds for future extensions, additions and improvements to the company's lines.

DETROIT UNITED RAILWAY COMPANY.

During the six months ended June 30, 1908, the Detroit United Railway earned an amount equal to 3.12 per cent on its $12,500,000 outstanding capital stock. This compares with an amount equal to 3.52 per cent earned during the first six months of 1907.

The reason for the less favorable showing this year is found in the heavy increase in charges, the increase being equal to 5.71 per cent. This increase was the principal cause for a decrease equal to the 11.37 per cent in the surplus after charges.

Below are shown the earnings for the six-month periods for both 1908 and 1907:

	1908.	1907.
Gross	$3,285,428	$3,286,869
Expenses	2,110,307	2,105,239
Net	1,175,121	1,181,630
Other income	28,609	28,239
Total income	1,203,730	1,209,869
Charges	812,973	769,078
Surplus	390,757	440,791

As the company's best months are those of July, August and September, a better showing for the last half of the year can be expected. During the year ended December 31, 1907, the company earned 8.88 per cent on its $12,500,000 capital stock. The amount available for dividends was equal to 6.71 per cent after the deduction of depreciation charges.

UNION TRACTION OF INDIANA.

Secretary William H. Forse, Jr., of the Union Traction Company of Indiana, in a circular to stockholders states that, owing to general business depression and a strike of a portion of the company's employés during January and February, gross earnings of the Indiana Union Traction Company for the year ended June 30, 1908, from all properties except those leased after June 15, 1904, do not amount to $1,850,000, and therefore no rental, based on gross earnings for such period, will be payable.

MASSACHUSETTS ELECTRIC COMPANIES.

The report of the Massachusetts Electric Companies for the quarter ended June 30 shows gross receipts of $5,328,088, an increase of $162,613 over the corresponding period last year. Net earnings after fixed charges show a gain in gross of $117,887, or 65.2 per cent. For the nine months operating expenses absorbed 68.7 per cent gross, compared with 71.4 per cent for the same three quarters of 1907.

PHILADELPHIA RAPID TRANSIT COMPANY.

While the annual report for the fiscal year ended June 30 of the Philadelphia Rapid Transit Company has not been made public, it is understood that the company carried 512,869,053 passengers during the year, an increase of 20,732,015. With the completion of the new elevated and subway line through the centre of the city it is estimated that traffic next year will show a much larger increase. Gross earnings were $18,288,000. Operating costs were a trifle higher, and the company will show a deficit for the year of approximately $92,000, as compared with last year's deficit of $364,048. With the payment of the remaining $7.50 due on September 7, the stock will be full paid and non-assessable. The payment of this assessment of $4,500,000 will clean up existing loans of $3,000,000 or more, and all payments on construction work.

TWIN CITY RAPID TRANSIT COMPANY.

The report of the Twin City Rapid Transit Company for the six months ended June 30 shows gross earnings of $2,982,849; expenses, $1,535,589; net earnings, $1,447,260; charges and taxes, $644,427; surplus for dividends, $802,-833; preferred dividend, $105,000; balance for common stock, $697,833.

LITTLE ROCK RAILWAY AND ELECTRIC COMPANY.

The Little Rock Railway and Electric Company reports for the month of June and six months ended June 30 as follows: June gross, $54,046; expenses and taxes, $30,270; interest and sinking fund, $10,-205; reserve and emergency fund, $3,000; net surplus, $10,570. Six months' gross, $330,732; expenses and taxes, $168,622; interest and sinking fund, $58,000; reserve and emergency fund, $18,000; six months' net surplus, $86,110.

BIRMINGHAM RAILWAY, LIGHT AND POWER COMPANY.

The Birmingham Railway, Light and Power Company, of Birmingham, Ala., reports for the month of June and six months ended June 30, June gross of $194,293; expenses and taxes, $118,647; interest and sinking fund, $43,846; June surplus, $31,800. Six months' gross, $1,064,825; expenses and taxes, $682,777; interest and sinking fund, $263,295; six months' surplus, $118,753.

KNOXVILLE RAILWAY AND LIGHT COMPANY.

The Knoxville Railway and Light Company, Knoxville, Tenn., reports for the month of June and six months ended June 30, June gross of $18,977; expenses and taxes, $24,933; interest charges, $11,421; surplus, $12,623. Six months' gross, $272,099; expenses and taxes, $144,697; interest charges, $68,677; surplus, $58,725.

ELECTRICITY IN AGRICULTURE.[1]

BY SIR OLIVER LODGE.

Some thirty years ago a Swedish professor named Lemström sought to elucidate the aurora borealis by trying to imitate its appearance by electrical experiments. For this purpose he produced high-tension discharges of various kinds, and sent them through vacuum tubes until he got an appearance very like those of the northern lights. Some of these experiments he conducted in his greenhouse, and he noticed incidentally that the plants seemed to thrive under the treatment, and that the electrification thus produced in their neighborhood appeared to do them good. He also noticed, as remarkable, the flourishing development of plants in arctic regions, where the sunlight was very weak, and he attributed part of this growth to the influence of electric discharges.

He says that when the plants in the north of Norway, Spitzbergen and Finnish Lapland have resisted the frequently destructive night frosts they show a degree of development which greatly surpasses that of plants in more southern regions, where the climatic conditions are more advantageous. This rich development appears principally in the fresh and clear colors of the flowers, in their strong perfume, in the rapid development of the leaves on the trees, and their scent, but particularly in the rich harvest which different seeds—such as rye, oats and barley—will produce when, as before stated, they are not destroyed by the frosts. From a bushel of rye sown they will often produce forty bushels, and from barley twenty bushels, and so forth. It is the same with grass. These results are attained although the people cultivate their soil very imperfectly, using only plows and harrows of wood.

He pursued the matter by careful observation, taking test plants in pairs or groups, electrifying one group—that is to say, discharging some electricity into the air above them—and keeping a similar group away from the electricity, in order to be able to compare them. Then he photographed the two groups side by side, and found in nearly all cases a marked improvement as the result of the electrical treatment. He concluded that the needle-like shape of the leaves in fir trees, and the beard on the ears of most cereals, had the discharge of electricity as their function, and found that they did act in this way.

It can hardly be doubted that the electrification of the air has some effect on growing plants. For it is found that, under the influence of sunshine, electrified plants can give off electricity into the air from the leaves, and the fact that the air is electrified relatively to the soil requires that the plants shall be electrified too, so that in all probability they are in a constant state of slow electrical discharge, which becomes more rapid when the sun is up. In what way this discharge of electricity from their growing tips and hair, and surface generally, really acts must be studied and reported on by physiological botanists; but it is natural to suppose that it can not be without influence and reasonable to think that that influence must be beneficial—a hypothesis which direct experiment confirms.

When, after some preliminary experiments at Bittin, J. E. Newman, of Gloucester, acting in conjunction with R. Bomford, of Salford Priors, determined to try the phenomenon on a really large scale, and came to me to see if I could help them electrically, and enable them to maintain a continuous high-tension discharge for hours together each day over ten or eleven acres by means of power furnished by an oil engine and dynamo, I very willingly assented and set my son, Lionel Lodge, upon the job.

The method is to stretch over the field to be treated a number of wires on poles, high enough for loaded wagons and all the usual farming operations to go on underneath the wires without let or hindrance. The wires are supported on the posts by elaborate high-tension insulators and they extend over all the acreage under experiment, a control plot of similar land under similar conditions being, of course, left without any wires.

The system of conductors is then connected at one post with a generator supplying positive electricity at a potential of something like 100,000 volts and with sufficient power to maintain a constant supply of electricity at this kind of potential.

Leakage immediately begins, and the charge fizzes off from the wires with a sound which is sometimes audible, and with a glow which is visible in the dark. Any one walking about below the wires can sometimes feel the effect on the hair of the head, as of a cobweb on the face. They are then feeling the stimulating action of the electrification.

The electrification is maintained for some hours each day, but is shut off at night; it is probably only necessary to supply it during the early morning hours in summer time, and in spring time or in cold cloudy weather for the whole day, or during the time of the plant's greatest activity. But at what stages of the growth of a plant the stimulus is most effective has still to be made out. However, in the case of wheat, both the ear and the straw are valuable, and the electrification is accordingly applied for a time each day during the whole period of growth until stooling begins.

The power required to generate the electricity is very small, for although the potential is high the quantity is insignificant, and the energy is accordingly comparatively trivial. It is known that even when natural atmospheric electricity has accumulated intensely, and has become a thunderstorm, the quantity even then is quite small, though the potential or tension is so enormous that the flashes are of astonishing violence and power while they last.

The electricity can be generated in more than one way. It can be generated by the revolving glass plates of a static influence machine, usually known in this country as a Wimshurst machine, or it can be generated by transforming up to high tension and rectifying to one direction the current of the revolving magnetic generator called a dynamo. The first is in many respects the simplest and was used in the early and small-scale experiments, but it can hardly be regarded as an engineering method adapted to continuous or rough use. The latter is the one which in the trials now to be described we have adopted.

The power is generated by a two-horse oil engine driving a small dynamo in an outhouse of the farm. Thence the current (three amperes at 220 volts) is taken by ordinary overhead wires to the field where they enter a suitable weather-tight hut which contains the transforming and rectifying apparatus. The only moving part here is the "break" and if the original dynamo had been an alternator even this might have been dispensed with. The transformer is a large induction coil specially made to stand continuous use and its current is rectified by means of vacuum valves in accordance with a patented device of my own.

The negative electricity is conveyed direct to earth, while high-tension electricity, all of positive sign, is led by a specially insulated conductor out of the shed to the nearest post of the overhead insulated wires, which are thereby maintained at continuous high positive potential.

The overhead system of wires covered

[1] Abstract.

about nineteen and one-half acres of ground. The wires were mounted on insulators placed upon larch poles some fifteen feet high, which were placed in rows, the rows being separated by a distance of 102 yards and the poles in a row being seventy-one yards apart. Stout telegraph wire carried the current down each row, while thin galvanized-iron wires, placed some twelve yards apart, were stretched between the rows, and acted as the discharge wires. In this way twenty-two poles were sufficient to support the wire over the nineteen acres. Roughly, only one pole per acre is required, therefore the inconvenience is practically *nil*.

Owing to the flexible suspension, risk of breakage to the wires is very small. During the two years the wires have been up at Bevington, apart from a few wires broken at harvest time by catching the top of an extra high wagon load, only one wire has fallen.

The acreage was spread over two different fields: In one field some eleven acres of wheat were under treatment; in the other six and one-half acres of barley and a half-acre plot planted with potatoes, mangolds, etc.

The wheat field was of eighteen and one-half acres extent, the remaining seven acres were sown with English (White Queen) wheat, one and one-half acres, and Canadian (Red Fife) on five and one-half acres. In the electrified part Canadian wheat occupied two and one-half acres, English wheat nine acres.

The results on the barley field, including the small plot, had to be neglected owing to the great local variations produced by the very irregular manuring the field had previously undergone; the wheat field, however, as far as one could judge, had been very uniformly treated previously.

In the wheat, a difference was noticeable at an early stage, the young blades on the electrified part being, in the opinion of many observers, of a darker green.

The crop was judged as considerably heavier by several practical observers, and the straw was, on an average, from four inches to eight inches higher. Both experimental and control plots came into ear at about the same time, but the Canadian wheat under treatment was ready for cutting some three or four days before the control area.

The following is a very brief summary of returns and information supplied to me by Mr. Newman and Mr. Bomford, showing the results from the electrified as compared with the control unelectrified plots.

SUMMARIZED RESULTS OF THE 1906 EXPERIMENTS.

Bushels of wheat per acre.

(Estimated corresponding increase in straw not measured.)

	From the Electrified Plot.	From the Unelectrified Plot.	Increase. Per Cent.
Canadian (Red Fife)...	35½	25½	40
English (White Queen).	40	31	30

Moreover, the electrified wheat sold at prices some seven and one-half per cent higher, several millers in baking tests finding that it produced a better baking flour.

The increase appears to be mainly due to better stooling. No marked difference was observable in the development of ears.

J. Kirkland, of the National School of Bakery, Borough Polytechnic, found the evidence from baking tests supported by the average of dry glutens from all his tests thus:

	Per Cent.
In the electrified	11.15
In the unelectrified	10.85

The somewhat poor yield of wheat obtained from the unelectrified portion of the field is probably explained by a deficiency in lime, which has now been rectified. Further, the wheat was spring sown, and red fife, under this condition, does not usually yield good crops. The experiments are being repeated upon wheat during the present season, and strawberries are also under treatment once more.

In 1907 wheat was grown again in the 1906 wheat field. Current was cut off from most of the barley field, which was down to clover and rye grass; eight and one-quarter acres in an adjoining field were planted with strawberries (Stirling Castle) in March, approximately two and three-quarters acres having a wire network erected over them. Mangolds were planted between the strawberry rows.

The wheat field during the early spring was given a dressing of lime, ten hundredweight to the acre, four hundredweight to the acre, bone meal drilled in; the unelectrified part was given one and one-half hundredweight sulphate of ammonia, and the electrified part three-quarters hundredweight. Barley had been grown on the strawberry field in 1906, and this was given ten tons to the acre of farmyard manure, which was plowed in.

RESULTS OF CROPS, 1907.

WHEAT.

(Variety—Red Fife, Spring Sown.)

Seven and one-half acres unelectrified gave 239 bushels thirty-eight pounds head wheat, fifteen bushels one pound tail.

Eleven acres electrified gave 455 bushels fifty pounds head wheat, seventeen bushels twenty-seven pounds tail.

Or, summarizing as follows:

BUSHELS PER ACRE (HEAD WHEAT).

Electrified, 41.4; unelectrified, 32; increase 29 per cent.

Electrified wheat brighter and a better sample. Increase due to better stooling and also better filling out of ears.

HOURS PLANT RUNNING.

1906, March 16 to July 10, inclusive; 621¾ on ninety days. Average electrical pressure corresponded to a three-quarters-inch spark.

1907, March 28 to July 27, 1,014 hours on 115 days. Average pressure corresponded to a one-half-inch spark.

STRAWBERRIES.

This being the first year, the crop was necessarily very small, and was picked chiefly to see if any increase had been obtained. The result showed a thirty-five per cent increase. Earlier ripening was also observed.

Mangolds—It was found impossible to weigh either the whole or a part of this crop. Estimated increase (from number of cartloads removed) twenty-five per cent. Analysis showed an increase in the sugar where electrified, but the results varied considerably.

Small plots of raspberry canes showed a marked improvement in growth. A curious point about the raspberries was that the foliage and fruit on the old canes showed no difference, but that the new growth, particularly after the old wood was cut back, showed an enormous difference in favor of the electrified. The manurial treatment was exactly similar.

Small plots of tomatoes also showed a large increase in the crop.

Those interested in the experiments are much indebted to the enthusiastic co-operation of Mr. Bomford. It may be interesting to note that it was at a farm belonging to Mr. Bomford's father that the first steam plowing in England was done.

Professor Lemström is undoubtedly the pioneer in this sort of work; though circumstances connected with the natural electrification of the atmosphere and with the discharge of electricity from various surfaces have been pertinaciously examined by Professors Elster and Geitel.

Professor Lemström published his results with full details and illustrations, both of the apparatus used and of the appearance of some of the resulting crops, in a small book called "Electricity in Agriculture and Horticulture," published in English by the Electrician Company, in 1904, and is well worth referring to.

The Abbé Berthelon, in 1783, raised a head of metallic points in the air, in the manner of a lightning conductor, and made it terminate in a series of discharge points just over the plants. He states that the use of this apparatus was invariably accompanied by an improvement in the appearance of the vegetation and by an increase in the fertility of the plants.

An opposite or control experiment was made by Grandeau in 1879 when he protected a plant from atmospheric electricity by means of a wire cage, and showed that its development was greatly retarded.

Other experimenters have done the same thing and made careful measurements of the results, which are all in the same direction.

Professor Berthelot compared the growth at the top of a twenty-eight-metre tower with that of plants growing at the foot, and considered that the greater growth at the higher level was largely due to the potential gradient in the atmosphere.

Dr. Cook, of Bristol, likewise obtained an increase in the rate of growth by the use of an overhead discharge on a small scale.

During the winter of 1904 Mr. J. E. Newman installed a small trial apparatus, consisting of a small influence machine of the Wimshurst type and overhead discharge wires, at the Golden Valley Nurseries at Bitton, near Bristol. The wires ran about sixteen inches above the tops of the plants, or above the rows of tomatoes in the glass houses, and short pieces of fine wire, with the free ends pointing downward, acted as discharge points.

From March 7 to July 26 the machine was running during 108 days for a period of 9.3 hours daily, principally at night.

In all cases control plots were provided, which, as far as practicable, were under identical conditions, and the very favorable results obtained led to the experiments on a larger scale above described.

The Annual Convention of the Brilliant Electric Company.

The annual convention of the officers, sales managers and representatives of the Brilliant Electric Company was held at Cleveland, Ohio, July 18, 19 and 20, headquarters being established at the Colonial Hotel. The three days' convention included business sessions and excursions to various points of interest for rest and recreation. On the morning of July 18 the representatives made a visit to the engineering department of the National Electric Lamp Association, where an address was delivered by Chief Engineer S. E. Doane. Later in the morning a trip was made on special cars to the Gates Mills, where luncheon was served, after which a baseball game was played between the jobbers and the salesmen. In the evening dinner was served at the Colonial Hotel, and addresses made as follows: "The Brilliant Electric Company," by M. H. Nason, vice-president of the company; "The Brilliant Lamp from a Jobber's Standpoint," C. K. Crossan, president of the Sweeten-Crossan Electric Company; "The Tungstolier," Milton Hartman, manager of the Tungstolier department; "Co-operation with the Jobber," by F. B. Galloway, of Cleveland; "The Diagnosis of a Lamp Man," by E. V. Hennecke, of Cleveland; "Modern High-Efficiency Illuminants," Herman Akhurst, of Cleveland; "Personality as a Business-Getter," D. W. Hopper, of Cleveland. The evening session was closed with an address by E. J. Kulas, secretary and general manager of the company.

On Sunday, July 19, the party made a trip on the steamer Eastland to Cedar Point.

On Monday, July 20, breakfast and luncheon were served at the Breakers Hotel, Cedar Point. In the afternoon the party left Cedar Point, and dinner was served at the Colonial Hotel, in Cleveland. At 9 P. M. there was a farewell supper at the Hofbrau, most of the members of the party leaving for Buffalo, where the jobbers' meeting was held.

Among those present were the following:

Herman Akhurst, Brilliant Electric Company, Cleveland, Ohio.

F. C. Barrington, Columbian Electrical Company, St. Joseph, Mo.

F. M. Bernardin, B-R Electric and Telephone Manufacturing Company, Kansas City, Mo.

M. G. Campbell, B-R Electric and Telephone Manufacturing Company, Kansas City, Mo.

E. E. Chase, Brilliant Electric Company, Cleveland, Ohio. Tungstolier department.

Thomas M. Cluley, Union Electric Company, Pittsburg, Pa.

Thomas Creaghead, Creaghead Engineering Company, Cincinnati, Ohio.

C. K. Crossan, Sweeten-Crossan Electric Company, Philadelphia, Pa.

H. H. Cudmore, Ambos-Cudmore Company, Cleveland, Ohio.

H. C. Downing, Downing Electric Company, Fort Dodge, Iowa.

G. O. D'Urfae, Brilliant Electric Company, Cleveland, Ohio.

F. B. Galloway, Brilliant Electric Company, Cleveland, Ohio. Tungstolier department.

L. Grieser, Cleveland Electrical Supply Company, Cleveland, Ohio.

Milton Hartman, Brilliant Electric Company, Cleveland, Ohio. Tungstolier department.

W. J. Hartwig, W. J. Hartwig Company, Detroit, Mich.

E. V. Hennecke, Brilliant Electric Company, Cleveland, Ohio.

H. B. Hewett, Cooper-Hewett Company, Louisville, Ky.

D. W. Hopper, Brilliant Electric Company, Cleveland, Ohio.

J. H. Hughes, E. B. Latham & Company, New York city.

W. C. Jones, Union Electric Company, Pittsburg, Pa.

L. H. Keller, Union Electric Company, Pittsburg, Pa.

E. P. Kinney, Capitol Electrical Engineering Company, Lansing, Mich.

A. C. Knight, Brilliant Electric Company, Cleveland, Ohio. Tungstolier department.

G. A. Knoche, Dunham, Carrigan & Hayden Company, San Francisco, Cal.

C. F. Koepge, Brilliant Electric Company, Cleveland, Ohio.

E. J. Kulas, Brilliant Electric Company, Cleveland, Ohio.

C. E. Ludovici, E. B. Latham & Company, New York city.

M. McGraw and representative, Interstate Supply Company, Sioux City, Iowa.

F. C. Maxheimer, Cleveland Gas and Electric Fixture Company, Conneaut, Ohio.

M. H. Nason, Cleveland, Ohio.

G. W. Provost, Union Electric Company, Pittsburg, Pa.

J. P. Provost, Union Electric Company, Pittsburg, Pa.

W. S. Reynolds, Brilliant Electric Company, Cleveland, Ohio. Tungstolier department.

Mark Simonton, Electric Supply and Construction Company, Columbus, Ohio.

F. D. Sweeten, Sweeten-Crossan Electric Company, Philadelphia, Pa.

R. H. Westbrook, Westbrook Brothers & Company, Greensboro, N. C.

One of the interesting features of the convention was the issue of "Daily Doings," published each day during the meeting. This contained the official programme and a great deal of interesting matter, personal and otherwise. The bulletin was edited by Milton Hartman, of the Tungstolier department, and contributed greatly to the success and enjoyment of the meetings.

THE TEST-METER METHOD OF TESTING SERVICE METERS—I.

BY JOSEPH B. BAKER.

The testing of meters at their places of installation by the use of indicating instruments is accurate, but is slow and correspondingly expensive.

The most serious disadvantage of the indicating-instrument and stop-watch method is the great amount of computation which is involved. The two sets of factors entering into the calculation—the disc constant of the meter and the number of seconds required for the disc to make a given number of revolutions, and the amperes and volts as read by the indicating instruments—must be reduced to watts in order to make them comparable. This operation may be summarized briefly as follows: The disc revolutions are multiplied by the meter's disc constant to obtain watt-hours, and this again multiplied by 3,600 to reduce to watt-seconds. This product is then divided by the number of seconds recorded on the stop-watch to obtain the watts recorded by the meter, which is then compared with the true watts, found by multiplying together the instrument amperes and volts. The computation is usually performed on a slide rule and occupies two or three minutes.

In order to facilitate the making of routine tests, *i. e.*, shorten the time and lessen the labor required to make the house-to-house tests without sacrifice of accuracy, standard rotating wattmeters have been employed instead of indicating instruments. In this method of testing as formerly practiced a carefully calibrated meter of the same capacity and disc speed as the consumer's meter is connected in circuit with the latter and the number of revolutions made by the two meters in a given time observed on a stop-watch; the test load being either the consumer's regular load or a determined load given by a lamp bank or rheostat. The portable standard was usually suspended from the consumer's meter by adjustable chains.

In the early method of comparison and calibration the main fields of the "standard meter" were connected immediately in series with the main fields of the consumer's meter and its potential circuit in parallel with that of the consumer's meter, so that one meter (A) was next to the mains and the other meter between A and the load. After throwing on the load (usually the consumer's regular load) the two discs, previously held still, were allowed to start at the same instant, and the "gain" of one over the other as the discs revolved was readily observed by sighting on marks on the edges of the two discs. After a few revolutions it became apparent whether the meter under test was "fast" or "slow," and the necessary cleaning of the consumer's meter, replacing of its jewel, adjustment, or what not, was done until the two discs ran in synchronism. Allowance was made, of course, for the lower registration of the meter which was next the load, due to the watts lost in the other meter. This method of testing was regarded as especially convincing to the customer whose meter was being tested, since the method was more comprehensible to him than a test by indicating instruments; but it was deemed advisable to connect his meter between the standard meter and the load, rather than the other way about, in order that he should not observe his meter to be running faster than the standard, when it was declared by the tester to be adjusted properly!

The time required to test a consumer's meter by this method is short compared to the time required to test with indicating instruments; and the procedure is simple, inasmuch as no error is introduced by variation of either load or potential (as on a motor load, for example), and there are no swinging instrument pointers to make readings difficult. On the other hand, a disadvantage of the method for routine testing as originally practiced was that it necessitated the daily checking and transportation of as many test meters as there were different capacities of customers' meters to be tested; since otherwise the tester must reduce the revolutions of the standard meter to an equivalent number on the meter under test, by slide-rule or pencil computations.

Sources of Error—Following are the principal sources of error in the use of a rotating wattmeter for testing, in the order of their importance. The sources of error, as stated, apply more particularly to direct-current meters of the commutator type:

(1) Differences in friction and vibration, especially when the test meter is running on light load. The uncertainty, as to accuracy on light load, of the portable standard—which was, of course, inherently quite as great as in the consumer's meter, under ordinary conditions, due to the magnitudes of the possible change in commutator and jewel friction as compared with the torque—was one of the two main disadvantages of its use for testing; the other being the need of having as many portable standards as there were sizes of consumers' meters installed. Changes in commutator friction may change the accuracy on one-tenth load as much as ten per cent in one day, and any heavy vibration, such as that caused during the test by a passing truck or trolley car, may change the accuracy for the time being to a very serious extent.

(2) Using the test meter before the potential circuit has had time to warm up to normal operating temperature, corresponding to the temperature of the consumer's meter. The test meter runs fast when first connected to the circuit, due to the fact that it is disconnected for a relatively long time, and thus has time to cool down, between the tests made at successively visited installations.

(3) Connecting the test meter on the wrong polarity, thereby causing error, especially on light loads, due to the stray fields from the braking magnets.

(4) Heat radiated by the series fields of the test meter when carrying a heavy load for a considerable length of time. This heat increases the resistance of the armature, causing it to run slightly slower.

It will be noted that the test-meter method possesses decided points of merit, while its disadvantages are mechanical and external, rather than inherent in the testing principle involved; so that if the disadvantages could be removed, the method, consisting as it does of a direct comparison of the consumer's meter with a standardized apparatus of identical type, would become an almost ideal way—accurate, quick and inexpensive—of testing a large number of consumers' meters in succession.

MODERN COMMERCIAL TEST METERS.

The manufacturers of the commercial test meters of the present day have sought to realize the advantages and eliminate the sources of error above described, by working along the following two separate and distinct lines:

A. The composite field construction and method exemplified in the Mowbray, Thomson and Fort Wayne test meters.

B. The method of employing a rotating standard meter of the same type and adjustable to the same capacity as the service meter to be tested, as exemplified in the Westinghouse multiple field rotating standard. An account of these three commercial test meters will be given in subsequent articles.

The Extension of the Telegraph.

From statistics made public by the German Government the following data have been compiled comparing the extent and cost of telegraph service in the various countries of greatest importance in the year 1906:

The United Kingdom leads in the number of messages sent—94,000,000; the United States has, however, the greatest number of miles of line—1,155,480; France has the lowest average cost of message—twelve cents.

	No. of Messages in Millions.	Average Cost per Message.	Total Receipts.	Miles of Line.
United States....	65.5	$0.42	$27,985,000	1,155,480
United Kingdom.	94.0	.16	15,247,000	384,109
France...........	58.0	.12	7,331,000	389,002
Germany.........	52.5	.15	8,290,000	458,358
Austria..........	19.0	.14	2,702,000	133,549
Italy..............	16.0	.21	8,472,000	128,582
Spain.............	5.0	.32	1,640,500	47,923

Statistics of Russia, Japan and other countries are incomplete.

The Brusio Hydroelectric Plant and Its 50,000-Volt Swiss-Italian Transmission System.

By Frank Koester.

THE largest and most recent hydroelectric installation in continental Europe is that at Brusio in the southeastern corner of Switzerland. Some 3,155 feet above sea level, bordered by the slopes of the Bernina Mountains, lies the lake of Poschiavo. This lake receives, among others, the waters of the River Poschiavino and its tributaries as well as those of the River Cavagliasco, which in turn collects the waters of the glaciers Cambrena and Palü. The total drainage area which feeds this lake is seventy-seven square miles. The area of the lake is 0.77 square mile and its greatest depth is 260 feet.

Owing to the high altitude of the lake the water supply in the winter time will be considerably less than during other seasons, consequently the equipment of the plant with proper regulating devices became very essential. Therefore one of the foremost requirements consisted in damming the lake at its outlet, where the River Poschiavino continues, so that the water level of the lake may be raised 3.3 feet above the normal and lowered by siphoning as much as 24.3 feet below the normal level, thus providing a natural reservoir giving a reserve water supply of 520,000,000 cubic feet.

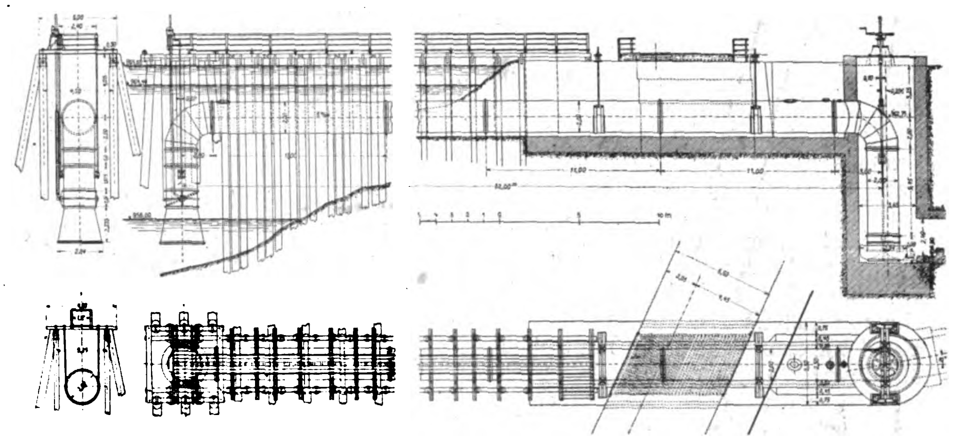

FIG. 1.—SIPHON SYSTEM AT LAKE POSCHIAVO POWER PLANT, BRUSIO, SWITZERLAND.

The headrace leading from the lake is carried to Monte Scala, a distance of 3.25 miles, by a tunnel through the mountain at a considerable depth, where a collecting basin is provided. The power plant is located at Campocologna, receiving the water through penstocks from the collecting basin under a head of 1,300 feet.

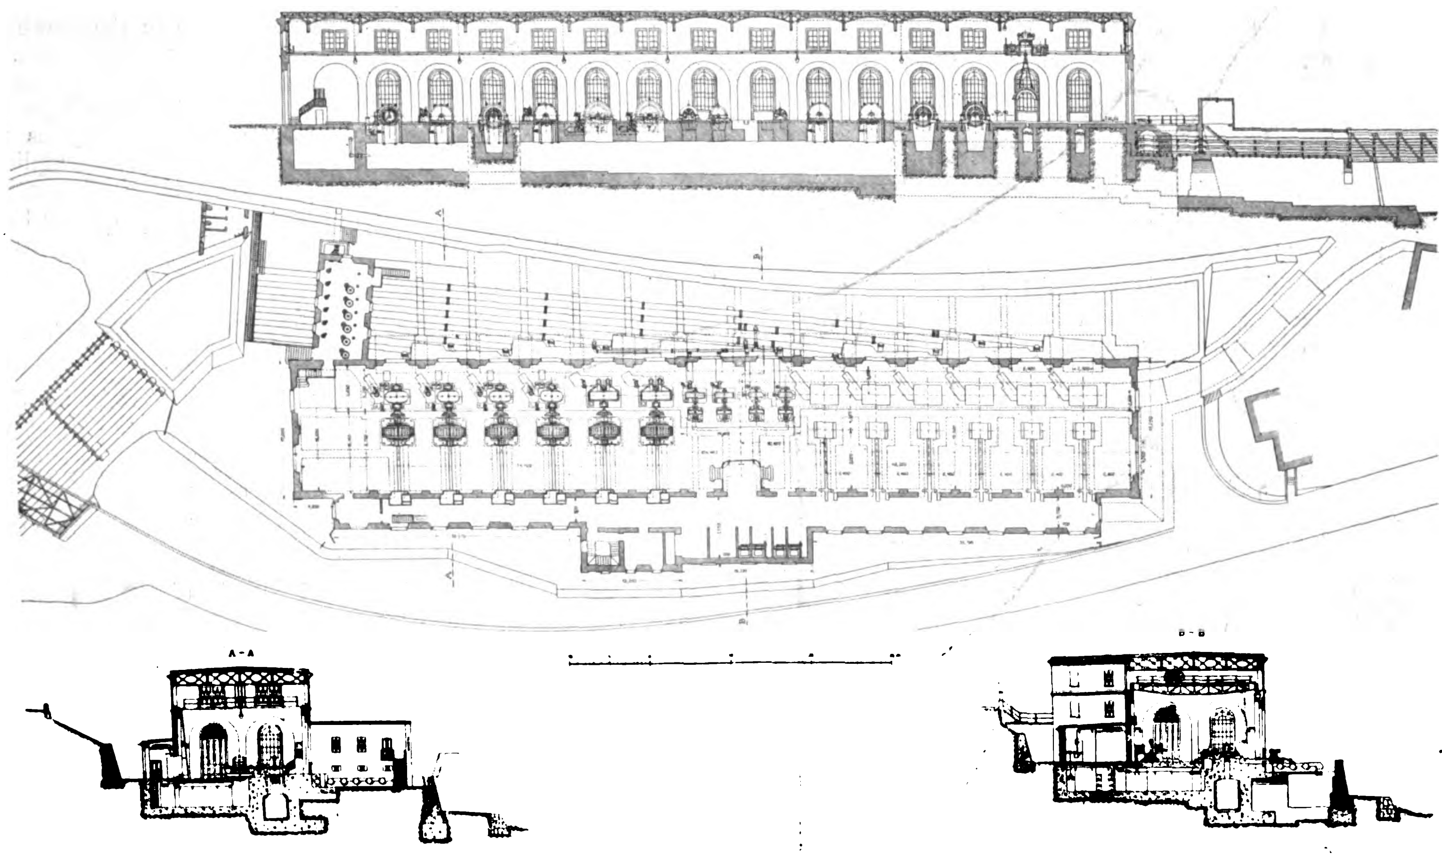

FIG. 2.—GENERAL LAYOUT OF POWER PLANT, BRUSIO, SWITZERLAND.

Current is generated at 7,000 volts and is transmitted through a tunnel across the boundary into Italy, where, at a substation in Piattamala, the voltage is stepped up to 50,000 for use by the Societa Lombarda, an Italian distributing company, to work in parallel with their well-known stations in Vizzola and Castellanza. This company guarantees the use of 16,000 kilowatts. From the power plant itself several aerial lines transmit current to various other consumers in Switzerland, and among them it will assist a small

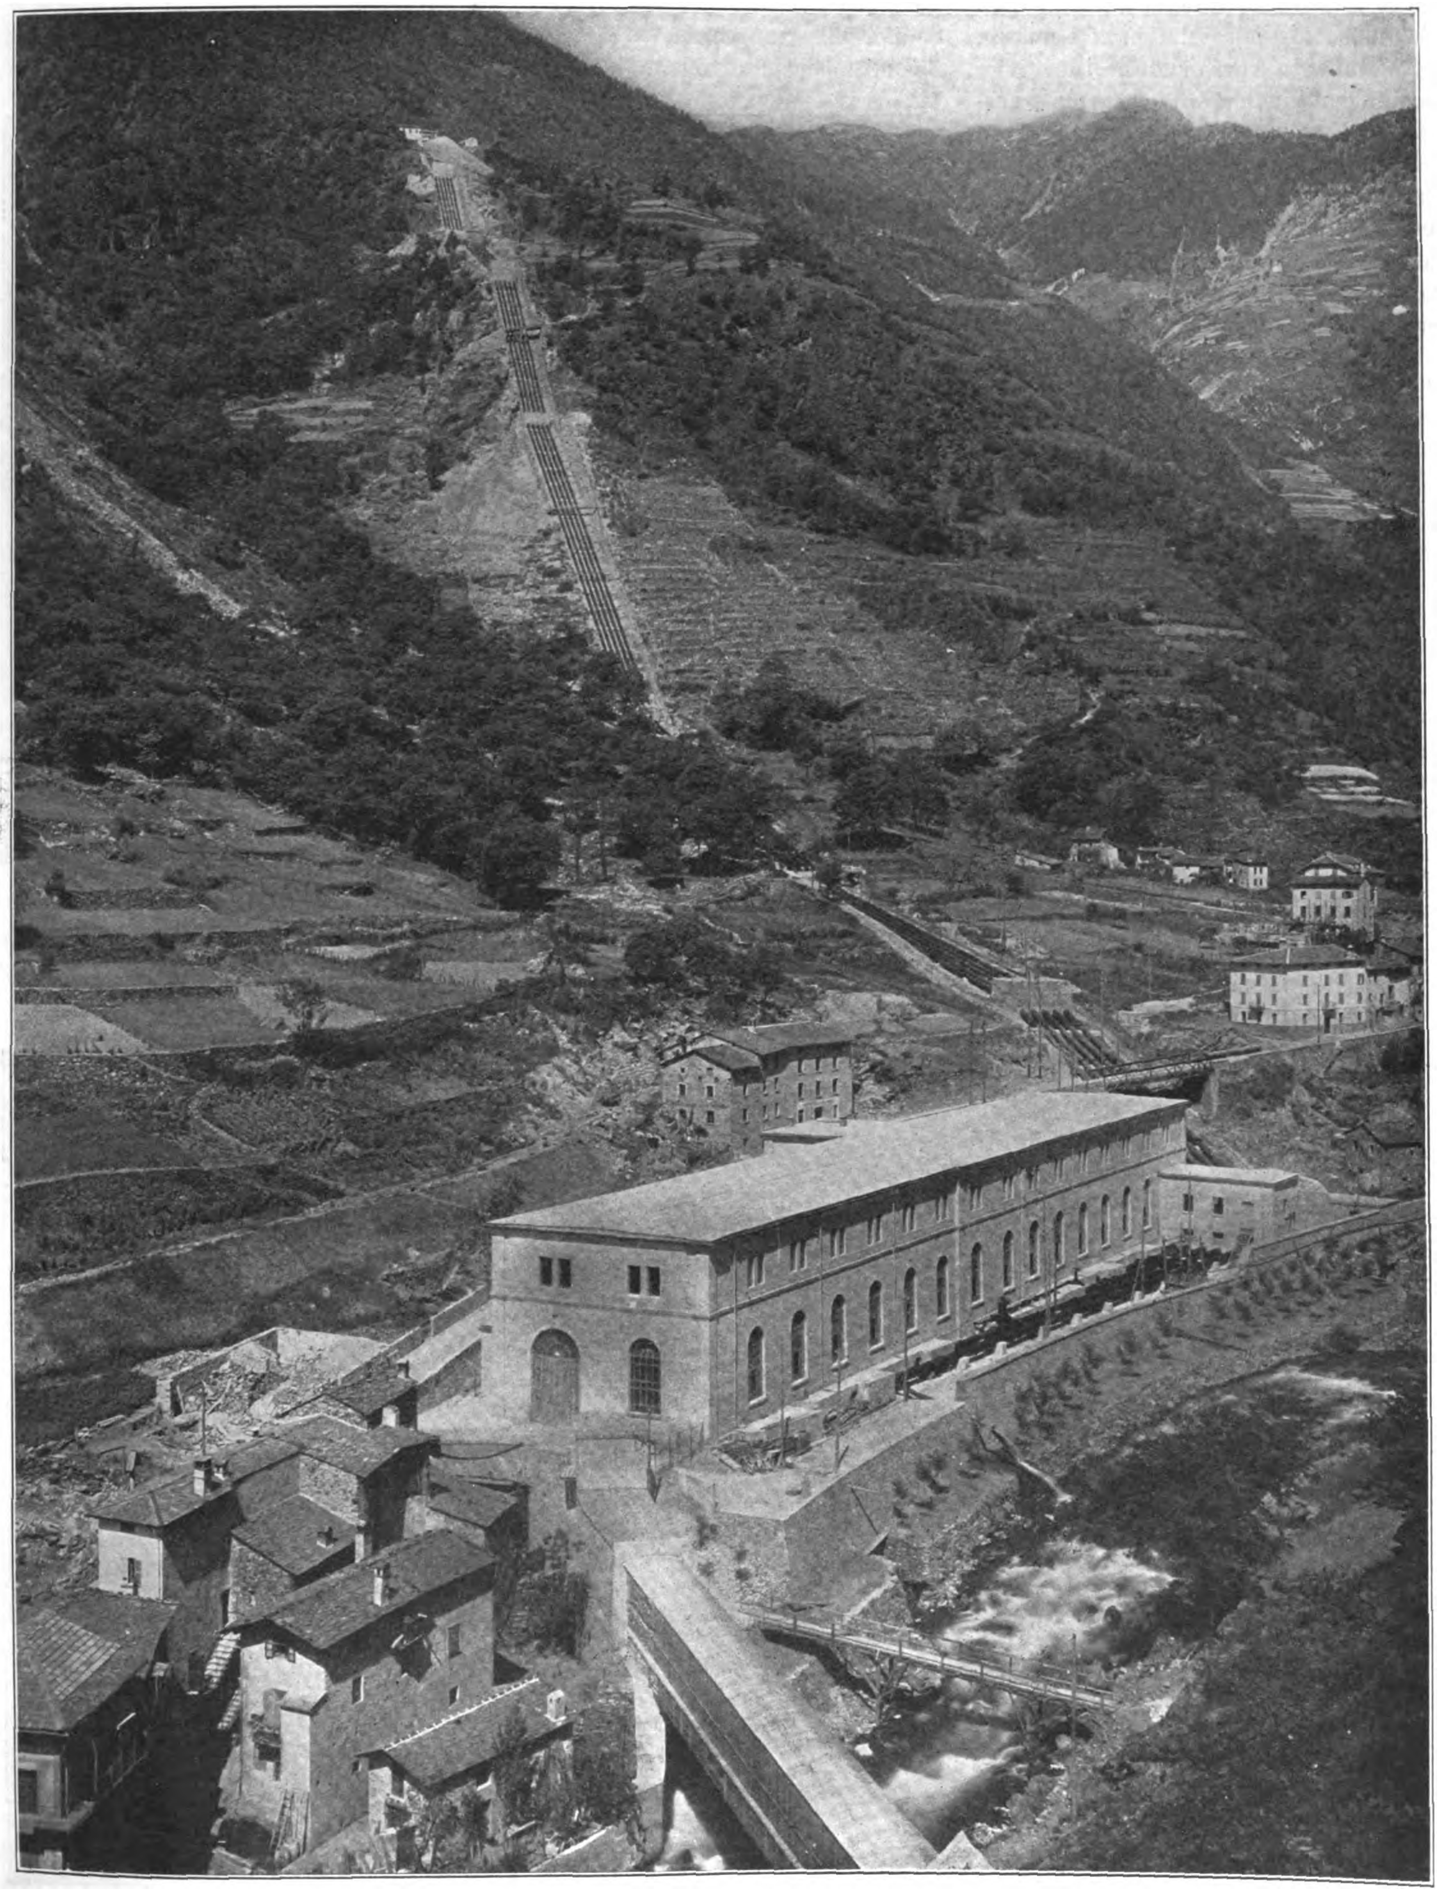

Fig. 3.—Power Plant at Brusio, Switzerland, Showing Also Penstocks and Cable Tunnel.

power plant still under construction at Sajento.

The 40,000-volt transmission line, from Piattamala to the substation at Lomazzo, is 88.5 miles in length and consists of two independent lines. A 20,000-volt transmission line branches off northward to Como from the station at Lomazzo, running a distance of thirty miles. An 11,000-volt line runs southward eight and one-half miles to the steam-power plant at Castellanza for assisting or drawing current from same. The bulk of the current is used for spinning and weaving mills, which begin operations at 7 A. M.; reaching its maximum in a half hour, the load remains steady up to 12 o'clock noon, dropping in thirty minutes to a few hundred kilowatts and again reaching its maximum at 1 P. M., where it remains up to 7 P. M. During the night only 2,000 kilowatts are necessary.

The entire hydroelectric development and transmission system is considered the most up-to-date in Europe, embodying many excellent examples of modern European practice.

SIPHON SYSTEM.

As the level of the water in the lake will vary in the neighborhood of thirty feet, the headrace tunnel is located 32.8 feet below the normal water level. It was not advisable to connect the tunnel directly with the bed of the lake, therefore a siphon was installed. For this purpose a shaft was sunk about seventy-five feet from the water's edge and carried 7.4 feet below the low-water level. The shaft is twelve feet in diameter and the portion below water-level was built under air pressure. From this shaft the headrace or supply tunnel, having a diameter of 8.9 feet at this point, leads to the collecting basin.

The lake is connected to this shaft by means of a siphon tube 6.5 feet in diameter and 270 feet horizontal length or body. The suction leg is twenty-six feet long, provided with a screen and butterfly valve, while the discharge leg is 27.7 feet long. The latter is provided at its bottom end with a disc valve for regulating the flow of water. The tube has a pitch of five feet in a thousand and is provided at its highest point with nozzles; one being three and one-half inches in diameter connected to a double-stage air-pump for starting the siphon, and the other, an eight-inch connection for a centrifugal pump which is used for cleaning the siphon tube and particularly the screen. Instead of using the air-pump for starting, the centrifugal pump may be called upon, in which case, both butterfly and disc valve are first closed. Fig. 1 shows the general arrangement.

Since about 180 feet of the horizontal length of the siphon is located in the lake under the normal water level, this portion of the tube, made in sections of thirty-six feet, was fitted at its ends with blank flanges and then floated to its position between piles and anchored to the framework of the piling. The final flange connections were made by divers.

SECONDARY WATER SUPPLY.

For the purpose of damming the water in the lake six sluice gates were built at the outlet of the lake, five of these gates being 13.12 feet wide and one being 6.56 feet wide. The smaller one, which is located lower than the others, is used for passing sand and gravel. Located at a right angle to the dam or sluice gates, is

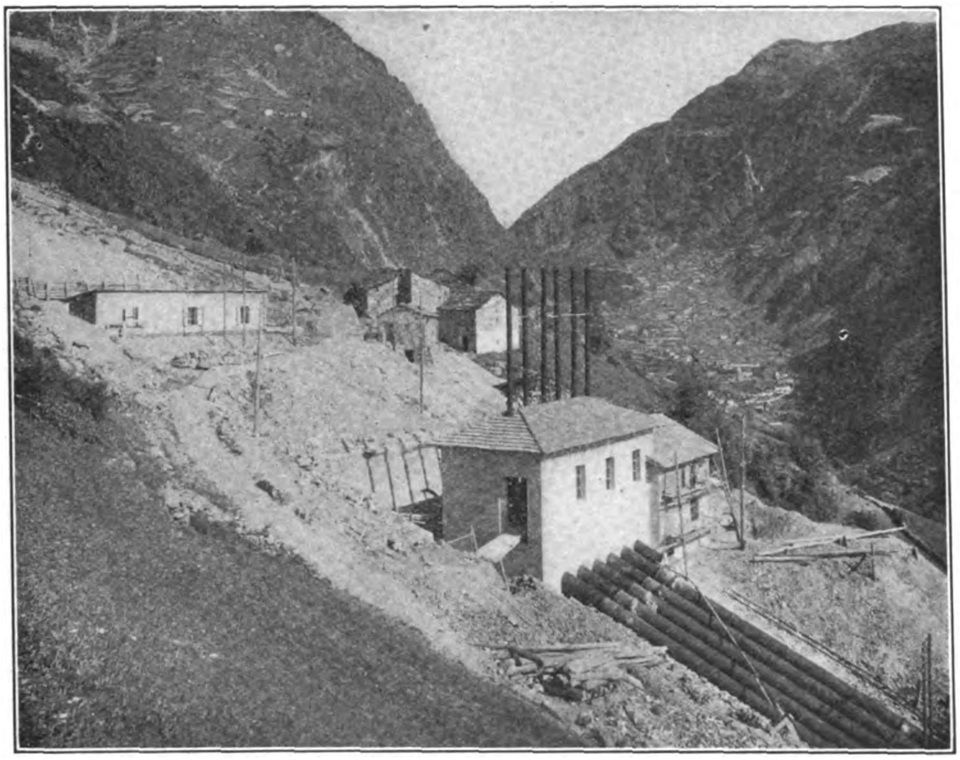

FIG. 4.—GATE-HOUSE FOR PENSTOCKS, HYDROELECTRIC PLANT, BRUSIO, SWITZERLAND.

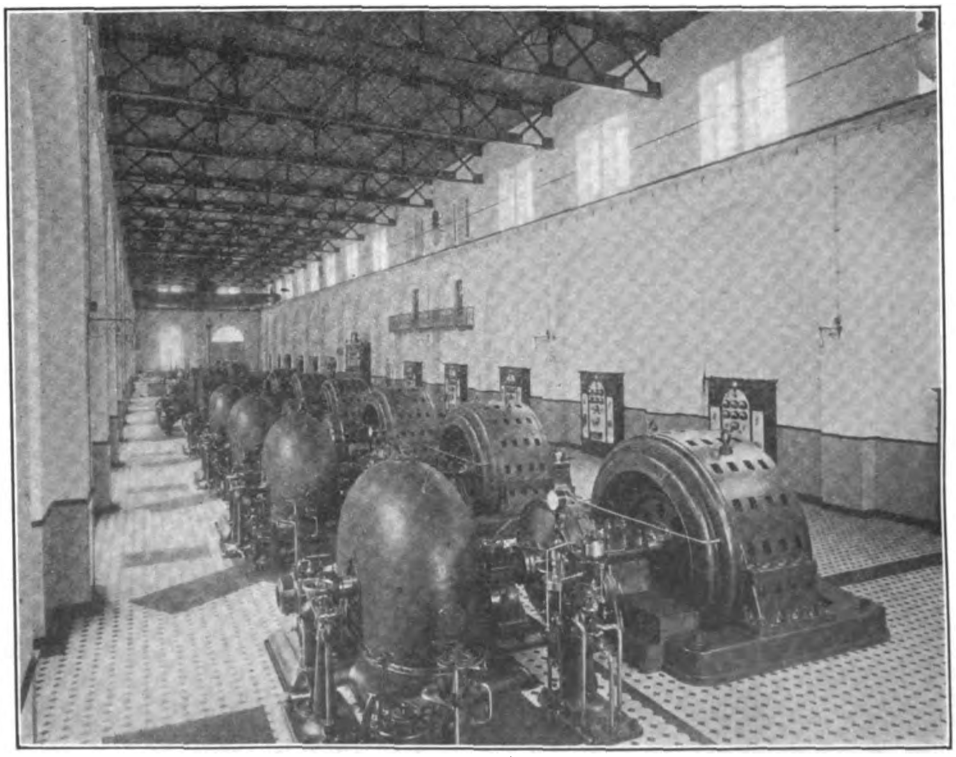

FIG. 5.—INTERIOR OF POWER PLANT, BRUSIO, SWITZERLAND.

a small basin provided with a screen. A thirty-three-inch pipe, provided with a gate, leads from this basin to the headrace tunnel, 800 feet below, where a shaft was sunk to receive the pipe; this arrangement, constituting a secondary water supply, was utilized in order to start up the plant at an early date. The size of this pipe was chosen so that it might later be used as one of the penstocks leading from the collecting basin to the power-house. This pipe by-passes the upper section of the headrace tunnel and the siphon system, furnishing the water supply during their construction pending the securing of necessary concessions.

HEADRACE.

The headrace is 17,056 feet long, 4,920 feet running through moraine (a formation similar to landslides) and the remainder through gneiss. A portion of the tunnel, near the collecting basin, lies about 100 feet deep, while the greatest portion of its length lies some 425 feet beneath the surface. With that portion of the tunnel lying at the greatest depth and running through the gneiss formation, no difficulty was experienced from seepage and air leakage, while in the portion nearest the surface, and where the tunnel runs through moraine, such difficulty was experienced. For the purpose of draining the seepage water and discharging the air, eleven lateral tunnels were cut having their outlet at the nearest point on the mountain slope.

The tunnel, where cut through the rock, was lined with concrete to a point above the water line, while the portion of the tunnel above the water was left unlined. Where the tunnel runs through the loose earth (moraine) it is constructed partly of concrete and partly of reinforced concrete, and where it was cut through the rock, pneumatic drills running on tracks were employed. For this purpose, and for lighting, a temporary power plant was installed, utilizing the fall of the Sajento River. The headrace was constructed of a wooden flume 910 feet long and a twelve-inch steel penstock. A fifty-horse-power turbo-generator, giving 4,000 volts, and the turbine also operated a two-step compressor supplying air at ninety pounds pressure through two main pipe-lines.

At three of the seepage discharge tunnels ventilators were installed during construction, while at the remainder ventilation was produced by means of branches from the compressed-air lines. Leading to the mouths of the seepage discharge tunnels Nos. 6 and 9, 1,000 to 1,500 feet above the valley, were electrical cable transportation lines.

At seepage discharge tunnel No. 2, near the lake, an overflow system is provided with a sand and gravel trap.

The entire tunnel, which is egg-shaped with a flat bottom, has a slope of two feet to the thousand and has a sectional area of fifty-three and one-half square feet. The average velocity of the water in the tunnel when partly filled is 6.5 feet per second. Should the possibility arise that in the future the tunnel should be used as a pressure tunnel, for which provision has been made, the velocity of the water will be five feet per second.

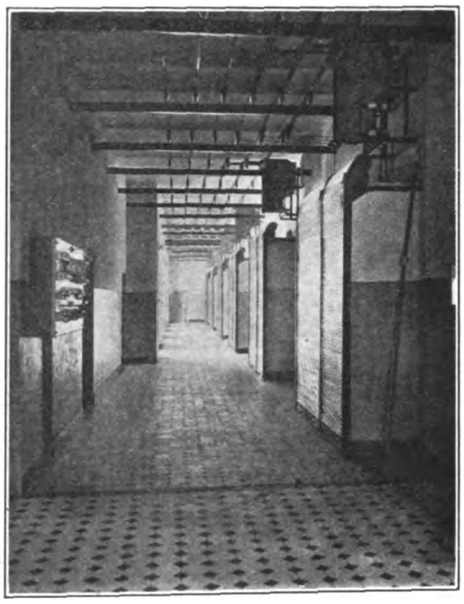

FIG. 6.—REAR OF SWITCHBOARDS AND GENERATOR BUSSES.

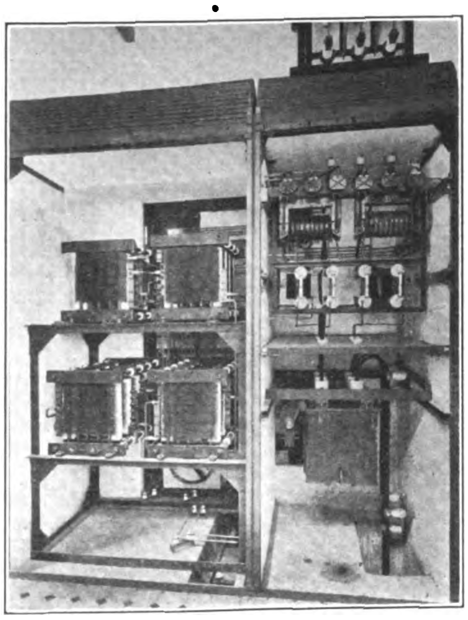

FIG. 7.—REAR VIEW OF INDIVIDUAL GENERATOR SWITCHBOARD.

As will be noted from the dimensions of the tunnel given above, the volume of water contained in same furnishes auxiliary storage capacity to the collecting basin. Furthermore, for a length of one mile the sectional area of the tunnel was increased, and in order to properly regulate the water supply to the collecting basin, an additional overflow was provided at the seepage discharge tunnel No. 9, discharging into the above-mentioned Sajento River. The collecting basin is so dimensioned that with average loads the level of the water will be constant, while with light loads the level of the water will be higher, and during the hours of maximum load the water level will be correspondingly lower.

COLLECTING BASIN AND PENSTOCKS.

The collecting basin is located 1,300 feet above the valley and is provided with six penstock connections arranged in pairs. The connections of each pair are located in separate chambers provided with screens.

The usual practice of providing the penstocks with cutoff gates has not been followed owing to the sudden rise and fall of the water. An automatic float arrangement for signaling the attendant was installed, operating by releasing a pawl and a magnet clutch and allowing a swing gate to close.

About 100 feet from the collecting basin is a gate-house through which pass the six penstocks. At the headgates they have a diameter of 33.5 inches and, owing to the high head (1,380 feet), considerable material was saved by reducing the diameter at the power-house to 23.5 inches by telescoping certain sections of the penstocks, thus giving at its lower end a velocity of 11.5 feet per second. The penstocks are made up of rolled steel in sections 39.36 feet in length. The heaviest material employed is seven-eighths inch. The sections are bolted together by the use of movable flanges. As will be seen in Fig. 2, the penstocks run down the mountain slope at various angles, at which they are anchored in solid concrete blocks, there being ten anchorages. Between these anchorages the penstocks rest on concrete piers, the expansion being provided for by the use of slip expansion joints. At the headgates (Fig. 4) each penstock is provided with a vent pipe about forty-five feet high. Drainage gates are provided at the lower ends of the penstocks for draining into the tailrace. Here the six penstocks are interconnected by a cross pipe having two outlets, one leading to the exciters, and the other being provided with a safety device, so that in case of excess of pressure the "bursting plate" gives way and relieves the penstocks. This cross-pipe connection also serves the purpose of maintaining a uniform circulation.

There are at present installed, corresponding to the main turbo-units, five penstocks. For hoisting the penstocks and other materials during construction, an electrically operated cable road was installed. The drum and motor are located in an annex to the gate-house near the collecting basin.

POWER-HOUSE.

The power-house (Fig. 2 and Fig. 3) is located at Campocologna alongside the River Poschiavino. The main generator room is 342 feet long by 56.4 feet wide. At the side there is a single-story switch annex 311.5 feet long by 10.75 feet wide, with a three-story central section for offices.

Owing to the topography heavy retaining walls were required, with deep and expensive building foundations. Up to the main generating-room floor the building is of concrete, while the superstructure is of quarried stone and tile. The roof construction is expensive and is as follows: Between I-beam purlins are large tile blocks, the undersides of which are glazed to form a finished ceiling. These are covered with a one-eighth-inch layer of cement over which are spread three layers of so-called wood-cement (consisting of sawdust and cement), between each of which is laid a layer of paper. Above the layers of wood-cement are reinforced concrete slabs, an air space of two and three-eighths inches being left between these slabs and the wood-cement. These precautions have been taken on account of the extreme heat in the summer time.

The building accommodates twelve turbogenerator units, each of 3,000 to 3,500 kilowatts' capacity, and four exciter units of 250 horse-power each. Ten of the turbo-generator units are at present installed. A twenty-five-ton electrically operated traveling crane serves the entire generating room.

TURBO-GENERATOR UNITS.

There are two different types of turbines installed: The Pelton wheel of Escher, Wyss & Company, of which there are at present four installed, two main and two exciter turbines, and the Girard turbine with partial admission, of Piccard, Pictet & Company, of which there are at present installed four main and two exciter turbines. The main turbines (3,000 kilowatts) run at a speed of 375 revolutions per minute and the exciters (150 kilowatts) at 430 revolutions per minute. The turbines are direct-connected to the water-wheels by flexible insulated couplings of the Zodel-Voith type.

The generators are 3,000-kilowatt, three-phase, fifty-cycle, 7,000-volt machines, and are designed for an overload capacity of twenty-five per cent. They

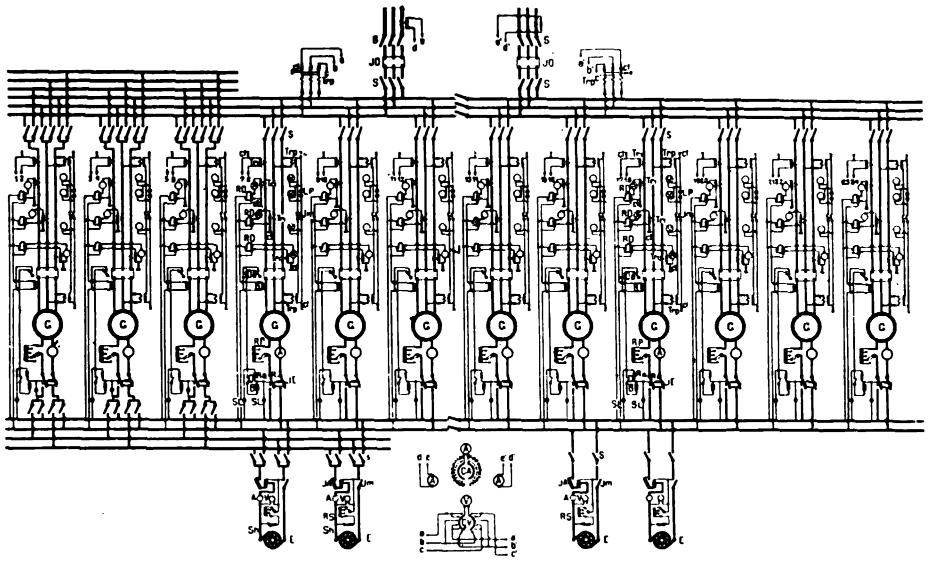

Fig. 8.—Wiring Diagram of Power Plant at Campocologna. A, Ammeter; B, Trip-Coil; CA, Ammeter Switch; CV, Voltmeter Switch; Ct, Ground Connection; Da, Auxiliary Switch for Trip-Coil; E, Exciter; G, Generator; JA, Overload Circuit-Breaker; JE, Field Switch with Discharge Resistance; Jm, Knife Switch; JO, Oil Switch; JOa, Automatic Oil Switch; LP, Synchronizing Lamp; Ra, Rheostat; RD, Relays; Ri, Discharge Resistance for Field Switch; RP, Series Rheostat; RS, Shunt Rheostat; S, Disconnecting Switch; SL, Pilot Lamp; Sh, Exciter Field; Tri, Current Transformer; Trp, Potential Transformer; V, Voltmeter.

are of the sixteen-pole, revolving field type. The poles are cast directly to the field ring. The stator is made in halves and has a bore of ten feet two inches, the width being three feet seven inches. The bedplate is made in two sections with the bearings cast on. The Elektrizitäts Gesellschaft Alioth, Münchenstein-Basel, Switzerland, manufacturers of the generators, who installed also the entire electrical equipment, guarantee the efficiencies as follows:

Power Factor, Cos φ = 1.	Cos φ = 0.7.	Load.
Per Cent.	Per Cent.	Per Cent.
93.5	92.0	0.25
95.0	93.5	0.75
96.0	94.5	1.00
96.5	95.0	1.25

The four exciters are of the six-pole, 115-volt, shunt-wound type. They develop 150 kilowatts at 430 revolutions per minute. Each exciter serves four generators with twenty-five per cent overload.

Contrary to the usual practice of centralizing the switchgear, because it was thought best for the convenience of operation and a material decrease in first cost and simplification of the wiring system, each generator has its own switchboard. As will be seen in Fig. 5, these switchboards are located against the wall next to the switchroom and directly opposite each generator.

Thus the station is divided into complete unit systems. However, to control all switchboards from one central point an instrument column has been installed as will be seen later on. The switchboards are of ornamental design and are faced with white marble slabs. All high-tension parts of the switchgear are located on the

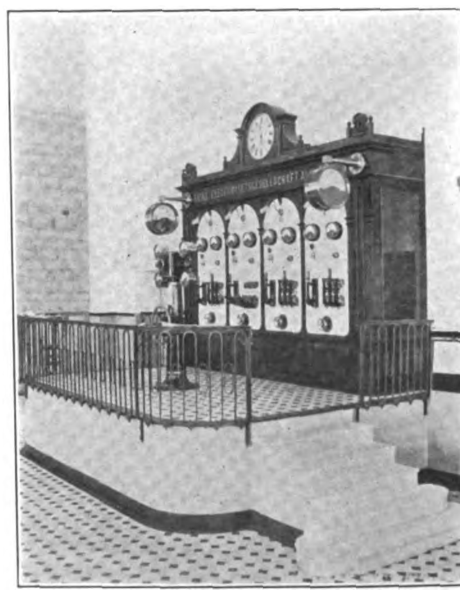

Fig. 9.—Exciter Switchboard and Control Pedestal.

opposite side of the wall (Fig. 6 and Fig. 7) in masonry compartments fitted with corrugated-iron rolling shutters. Each generator switchboard is equipped with the following instruments: Two voltmeters; one synchroscope, with phase lamps; three ammeters, one for each phase; one three-pole oil switch, which may be operated by hand or automatically. There are, further, an ammeter on the central column, a main-current rheostat for excitation, and a field-discharge resistance.

Owing to the non-centralization of the switchgear system it was not considered necessary to install a double bus-bar or ring system so common in Swiss practice. Fig. 8 represents the wiring diagram and it will be noted that there is one main and one exciter bus-bar system. Both systems are divided in the middle by sectionalizing switches. It will be further noted that the three generators at the left, which may also be independently excited, may be thrown upon a separate bus-bar group. The current from these three generators is intended for the Valley of Brusio and for the operation of the Bernina Railway.

The outgoing feeders, with the exception of those just mentioned, are connected at the middle of the bus-bars, which are made up of copper strips two inches by three-sixteenths inch, the area of each strip being sufficient for one generator. Thus, where each generator connection joins the bus-bar an additional layer has been added. The bus-bars run the entire length of the switchroom, above the aisle and close to the ceiling. They are carried on petticoat insulators fastened to I beams and are securely anchored in the middle and at the ends, so that in case of a severe short-circuit the different phases will not be thrown together.

The exciter switchboard (Fig. 9) is located upon a platform in the middle of the generator room opposite the exciters. It is provided with four white marble panels, one for each exciter, and upon each of which are mounted a voltmeter, ammeter, knife switch, shunt rheostat and a Reversite circuit-breaker.

In front of the exciter switchboard is the above-mentioned central instrument column upon which are mounted the following instruments: An ammeter, with multiple-throw switch, to read the current of each generator; one voltmeter, with plugs, for each phase; two ammeters, one for each of the outgoing feeder-systems of the Societa Lombarda, and one hand wheel operating a shaft to which are connected the shunt rheostats of the four exciters. From this column one attendant may control the operation of the entire plant.

(To be continued.)

Illuminating Engineering Society.

The second annual convention of the Illuminating Engineering Society will be held at Philadelphia, Monday and Tuesday, October 5 and 6. The headquarters will be at the Hotel Walton, Broad and Locust streets, and the sessions will be held in the auditorium of this house.

As this meeting will take place on the first two days of the Founders' Week, when a great many out-of-town guests are expected at the hotel, it will be advisable for all members of the society to arrange for their rooms in time.

The following is the provisional programme for the meeting:

President's address, Dr. Louis Bell.

Architecture and Illumination, by Emil G. Perrot.

Modern Gas Lighting Conveniences, by T. J. Litle, Jr.

Railway Car Lighting, by H. M. Davies.

Relation Between Candle-Power, Voltage and Watts of Different Types of Incandescent Lamps, by Dr. F. E. Cady.

Illuminating Value of Petroleum Oil, by Dr. A. H. Elliott.

Structural Difficulties in Installation Work, by J. R. Strong.

Street Lighting Fixtures, Gas and Electric, by H. Thurston Owens.

Oil Burners, by W. T. Sterling.

Design of the Illumination of the New York City Carnegie Libraries, by L. B. Marks.

Intensity of Natural Illumination Throughout the Day, by L. J. Lewinson.

Calculation of Illumination by Flux of Light Method, by J. R. Cravath and V. R. Lansingh.

Specific Intensity of Lighting Sources, by J. E. Woodwell.

Design of Reflectors for Uniform Illumination, by A. A. Wohlauer.

The Ives Colorimeter in Illuminating Engineering, by Dr. H. E. Ives.

International Unit of Light, by Dr. E. P. Hyde.

Some Experiments on Reflections from Walls, Ceilings and Floors, by V. R. Lansingh and T. W. Rolph.

It is possible that some slight changes may be made in this, but such is not anticipated. The Convention Committee is planning to send each member of the society, who indicates his intention to attend the convention, advanced copies of the papers. The meeting will be then conducted by reading papers in abstract, leaving almost the entire time for discussions.

In addition to the many entertainments in celebration of Founders' Week, the Convention Committee is preparing special features for the visiting members. Further information may be obtained by addressing George Ross Green, chairman of the Convention Committee, Tenth and Chestnut streets, Philadelphia.

Electrical Utilities in Zanzibar.

The Zanzibar Railroad Company, the Zanzibar Electric Light Company, and the Zanzibar Telephone Company are three American corporations doing business in Zanzibar. The Zanzibar Railroad Company has built and is operating a line of narrow-gauge railroad from Zanzibar City to Bububu, seven miles distant. According to the Washington (D. C.) *Herald* it is proposed to extend this road the entire length of the island, which will then form one of the principal means of communication between Zanzibar City and the Island of Pemba. The railroad starts at Palace Square in the city, and after running through the Malindi district of the city and the Indian Bazaar follows the west coast of the island to its northern terminus. The trains consist of a locomotive built in Pittsburg, Pa., and two open cars and one chair car, built by the Brill Company, of Philadelphia. The chair-car fare from one end to the other is one rupee, about thirty-three cents. The fare on the open cars is considerably less. The road is well built with iron ties and good-sized rails, but the climatic conditions of Zanzibar reduce the life of an iron tie. Little grading was required for the railroad, since the highest point on the island is said to be only 300 feet above the sea level.

The Zanzibar Electric Light Company has a splendid plant. It is modern in every respect, and furnishes good light and service. The Sultan's palace, as well as the houses of the Sultan's family and retainers, is wired and lighted throughout. By means of a tower studded with incandescent lights, having an aggregate lighting capacity of 3,000 candle-power, the palace square is always brilliantly lighted. The streets are also well lighted by means of incandescent lights.

The telephone is steadily making its way into a great many business and official houses of Zanzibar, and bespeaks Zanzibar's progress in introducing modern inventions and installing all the facilities enjoyed by European and American towns of the same size.

Wireless communication was recently established between Zanzibar City and the Island of Pemba. It is said that the messages are sent in Swahili, which is the language of the natives of Zanzibar and the parent of a great many native languages of the coast.

THE TESTING OF HIGH-VOLTAGE LINE INSULATORS.[1]

BY C. E. SKINNER.

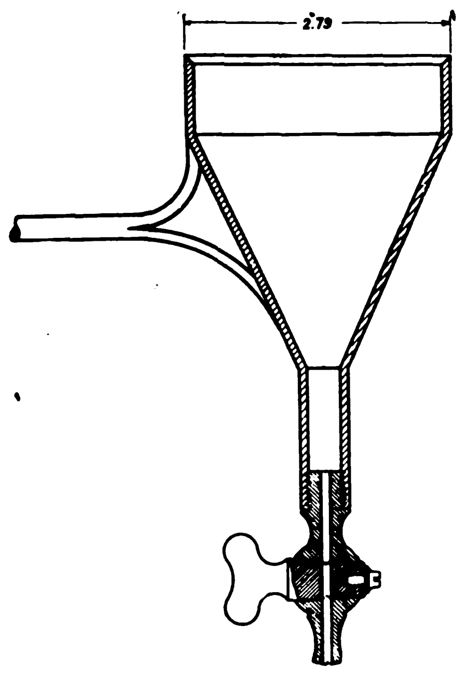
The specification herein proposed as standard for the testing of high-voltage line insulators was written at the request of the chairman of the High-Tension Transmission Committee in order to bring this matter before the Institute for discussion. It is not presented as representing the writer's personal opinion so much as an endeavor to harmonize information which he has obtained from various sources with the view of producing such a specification. Quite a large number of porcelain manufacturers and others interested in the testing and use of high-voltage porcelain line insulators in this country and in various parts of Europe have been consulted, and the information received is embodied as far as possible in the proposed specifications. It is fully appreciated that differences of opinion may exist on any point which is incorporated in such a specification. The fact that such differences do exist, and that tests are so different in different places, seems to the writer to be ample justification for the attempt at a specification which can be used by all as a standard of reference.

At the present time it is almost impossible for one familiar with a certain method of testing to base any judgment whatever as to the bearing of results obtained by some one else who uses a different method. If, after thorough discussion, and any revision which may be found essential, a specification is produced which will allow direct comparisons to be made of the performance of insulators of different types tested in various places and at different times, the object of the specification will have been in part accomplished. If a specification is evolved which can be accepted as a standard performance specification for line insulators in general, the uncertainty regarding comparisons of tests at various places and the widely varying requirements now insisted upon for conditions which are practically the same, will have been eliminated.

The specification naturally divides itself into three general parts. The requirements of routine tests are placed first, as it is considered that any tests of a routine nature which are required on insulators for the acceptance of any lot should naturally form a part of the tests made to determine the limitations of design.

The question of routine inspection for mechanical flaws and other defects is difficult to outline definitely, as a complete description of all points which might constitute cause for rejection would make the specification unduly long and complicated, and it is therefore usually considered better to leave this to the judgment of the inspector.

Some difference of opinion has been expressed as to whether the dielectric test on each individual part of insulators made up of parts should be included in the routine test instead of in the design test. It is the writer's understanding that such tests are invariably made by the porcelain manufacturers for their own information, whether specified as a part of the routine test or not, and it would therefore seem that there should be no very great objection to their being included in the routine test.



SPECIAL RAIN GAUGE.

It is possible that in some designs the voltage tests specified can not be met by certain shells which are used next to the pin for the purpose of increasing the dielectric strength when the other parts of the insulator are wet, due to the short surface distance. If the surface distance on the short shell is so small that this test can not be reached, it is probable that the object of inserting the short shell is in some measure defeated in the particular design. It might be possible to substitute a fixed test for each individual part of a shell independent of the voltage on which the insulator is to be used, as it is difficult if not impossible to get porcelain to stand tests of above 60,000 to 70,000 volts, regardless of the thickness. The better material in the thinner shells gives results equal to the poorer material in the thicker shells, due to shrinkage cracks and other defects which it is ordinarily impossible to eliminate in thick porcelain. The provision to exclude insulators which show excessive local heating is inserted for the reason that those familiar with such tests may at times be perfectly sure that an insulator is unsatisfactory even though it is not punctured. The term "localized discharge" as used does not mean the discharge which occurs uniformly around the insulator at the point of contact, but a discharge at some point on the surface; such discharge sometimes indicating a spongy material which will eventually give trouble.

Under design tests the amount of pull to be applied to the insulators is not specified for the reason that the strength must necessarily depend on the particular design, and the figures to be inserted, of course, should be agreed upon in each case between the manufacturer and the user.

The rate of precipitation specified in the rain test is probably greater than will ever be experienced except in very excessive storms, and even then only for a very limited time. The rate specified is less than that used as standard in some parts of Europe. A fairly wide limit of variation in rate is allowed, partly on account of the great difficulty in securing a perfectly definite and uniform rate, and partly from the belief—borne out by rather limited tests—that little difference in the results of tests will be obtained between the limits specified. It is desirable in the discussion of this paper that as much information as possible be brought out relative to the best possible method of obtaining a satisfactory spray.

The requirement that the insulator shall be tested with the pin at an angle rather than to attempt an angular rainfall is given for the reason that a satisfactory method has not yet come to the writer's attention for the obtaining and maintaining of a satisfactory angular rainfall, under the conditions which usually obtain where insulators are to be tested. It is far easier to incline the insulator and use a vertical precipitation, and it is considered far more probable that results can be repeated than by providing for an inclined precipitation.

The use of a rain gauge for determining the rate of precipitation is specified, as the writer has found it nearly impossible to get the rate of precipitation by measuring the flow of water through the supply pipe, which is frequently done. The diameter is limited to three inches for the

[1] A paper presented at the annual convention of the American Institute of Electrical Engineers, Atlantic City, N. J., June 30, 1908.

reason that a larger gauge would disturb the distribution of the spray to some extent. The type of rain gauge illustrated herewith is suggested as convenient and as having been found satisfactory in tests where it has been used. The diameter of the funnel is so chosen that the precipitation for any elapsed time measured in cubic centimetres and divided by 100, gives the rate of precipitation in inches for that elapsed time. By means of the valve at the bottom the water may be run into a standard chemical burette, and quite accurate measurements made. In use the rain gauge is inserted upside down into the spray, and then quickly turned to the upright position when the location to be measured is reached. A suitable card or other covering is then quickly placed over the top at the end of the elapsed time. It would, of course, be easy to provide a lid which could be opened and closed, in place of the method specified.

The writer would lay special emphasis on the importance of the dew test as probably determining the most severe condition which the insulator will ever be called upon to meet in practice. Also the fact that such a test is more nearly capable of exact repetition than any precipitation test. Furthermore, in such a test the moisture on the surface of the insulator must be perfectly clean water if the insulator itself is clean, and therefore is more like natural rainwater and eliminates any possibility of variations due to the quality of the water used.

PROPOSED STANDARD SPECIFICATIONS FOR THE TESTING OF HIGH-VOLTAGE LINE INSULATORS.

General—This specification is intended to provide a standard method of making tests on porcelain insulators or their equivalent which may be designed for use on transmission systems of 6,000 volts or above. The specification is intended to provide a means of determining the performance of any insulator, and is not intended to restrict design in any way whatsoever. The specification is divided into three parts as follows:

1. Routine tests, or tests to be made on each individual insulator, to show whether or not workmanship, materials and dielectric strength are up to the required standard.

2. Design tests, or tests to show the limitations of a design under a specific set of test conditions.

3. Methods of Testing—The methods to be followed in making the various tests specified, are separated from the body of the specification as a matter of convenience for reference.

1. ROUTINE TESTS.

a. Inspection—Each insulator shall be inspected to see that it is reasonably free from mechanical flaws, defects of glazing and cementing, chipping, etc. Those parts of the insulator which are to be fitted to caps, pins or other fastening devices shall be sufficiently close to design dimensions to insure first-class work in assembling and mounting. The general over-all dimensions shall not vary more than plus or minus five per cent from the designed size.

b. Dielectric Tests—When tested dry each shell of insulators of the cemented type and each unit of insulators made up of units, shall withstand for a period of five minutes three times its proportion of the line voltage, based on the total number of shells or units of which the insulator is composed. (For example, each shell of a four-part insulator shall withstand three-fourths times the normal line voltage on which the insulator is to be used, for a period of five minutes.)

When tested dry each completed insulator shall withstand for a period of five minutes 2.5 times the line voltage on which it is to be used.

If any shell of any insulator shows excessive localized discharge without puncture, the test on same may be continued for two additional periods of five minutes each. Excessive local heating or excessive localized discharge shall, if continued, be considered a failure.

Insulators not to exceed five per cent of any lot shall be tested for flashover by raising the voltage gradually, or by steps of not more than five per cent, until flashover occurs. If there is failure by puncture of more than one-half of those so tested, the flashover test may be required on all insulators of the lot on order.

2. DESIGN TESTS.

Tests to determine the limitations of any particular design are to be made on a few insulators, not more than five per cent of any particular lot on order.

a. Mechanical Tests — Insulators mounted on pins shall withstand a side pull exerted on the tie groove at right angles to the axis of the pin, of .... pounds. Cemented insulators and insulators made up of units shall withstand a direct pull along the axis of the pin, or equivalent, of .... pounds, the force being exerted between the cross-arm and the line fastenings.

b. Routine Tests—Insulators must successfully withstand tests under the heading of routine tests.

c. Rain Tests—In addition to the routine dielectric tests, the insulators shall withstand the following dielectric test when subjected to artificial rain. With a vertical precipitation of not less than 0.3 inch per minute, and not more than 0.4 inch per minute, the insulator in normal position mounted on a crossarm or its equivalent, with pin with which it is to be used, the complete insulator shall withstand for five minutes 1.5 times the normal voltage of the line on which it is to be used. With the same rate of precipitation and with the cross-arm so turned that both the cross-arm and the insulator pin are at an angle of forty-five degrees to the vertical, the complete insulator shall withstand for five minutes 1.25 times the normal voltage of the line on which it is to be used.

d. Dew Test—With the insulator cooled to zero centigrade, or below, and then placed in a moist atmosphere of thirty degrees to forty degrees centigrade, it shall withstand 1.25 times the normal line voltage after the insulator has become thoroughly covered over its entire surface by the condensation of moisture from the atmosphere.

3. METHODS OF MAKING TESTS.

a. Mechanical Test—The strength test of the insulator may be made by any suitable means of obtaining the specified pull. For this test pin insulators should be mounted on the pin with which they are to be used in practice, and a heavy copper wire or cable looped in the tie groove in such a way that there will be no injury exceeding that which would occur from the application of the standing tie. Insulators of other types shall be tested by having the pull exerted between the mounting intended for the crossarm and the line wire.

b. Dielectric Tests—Dry Test—The surface of the insulator shall be clean. The test on pin type insulators shall be made by placing the insulator upside down in a pan of water to a depth just sufficient to cover the tie groove or equivalent. This pan with water forming one testing terminal should be as small in diameter as possible and so arranged that the striking distance over the surface of the insulator is not reduced. Water shall be placed in the pin hole of the insulator, covering that portion of the insulator which would come in contact with the pin or equivalent. When insulators have metal thimbles placed in the pin hole or are mounted complete with metal pins, the thimbles or pins may be used in place of the water in the pin hole. Connection to the water in the pin hole forming the other testing terminal shall be made by means of any suitable metallic conductor, which must be so placed that it is central with the pin hole and extends far enough above the insulator so that it will not shorten the striking distance from the wire groove to this conductor. In testing the shells of insulators made up of concentric shells, tests shall be made from a pan of water in which the insulator is placed upside down as one terminal, to water placed inside the shell as the other terminal, the depth of water in the pan and in the shell being so arranged as to cover that part of the insulator which will be in contact with the cementing material. In testing units of insulators made up of units, the testing terminals shall consist of the metal mountings or their equivalent, with which the insulators are to be used in practice.

Rain Test—The rain test shall be made by mounting the insulator on a metal pin or equivalent, so arranged that it may be placed either vertically or at an angle of forty-five degrees to the vertical. Clean water shall be used and the precipitation shall be such that the water falls in a fine spray and in practically a vertical direction and at a rate of from 0.2 inch to 0.3 inch per minute, over the area formed by the vertical projection of the insulator. The rate of precipitation shall be obtained by the use of a suitable rain gauge of not more than three inches in diameter.

Frequencies—Dielectric tests shall be made at the standard frequencies of either twenty-five or sixty cycles per second. Any frequency between twenty-five and sixty cycles will be considered as meeting the specification. Lower or higher frequencies will be considered as special.

Voltage Control—When only a very limited number of insulators are tested in parallel, the test voltage may be taken from a constant-potential source and applied directly or it may be raised to the required value gradually. When a considerable number of insulators are tested together, the test voltage shall be raised to the required value smoothly and without sudden large increments and then applied for the prescribed interval. Flash-over tests and other tests requiring variation of voltage shall be made by raising the voltage to the required value smoothly and without sudden large increments.

Illumination of a Large Office.

Office lighting is rightly regarded as one of the difficult problems in illumination. Bookkeeping requires close application and demands such constant service of the eyes that office men are notoriously sensitive to the lighting conditions. Especially is this true in a large office where many employés are grouped together. Architects are giving more and more thought to the provision of suitable day illumination, while the demand for improvement in artificial illumination is even more imperative.

Daylight Photograph of the Office of the Stanley Works, New Britain, Ct.

The simplest and most common method of office lighting is to provide small individual units in the form of desk or drop lights. In many cases this is the best available form of illumination, especially when the working illumination is required only at isolated points. Perhaps the most serious fault to which this method of illumination is commonly subject is the glare of the lamps themselves or of the light reflected from desks or papers.

It is not unusual on entering an office

to find the fixtures draped with all kinds of shades and provided with the highest power lamps obtainable. This is an indication of unsatisfactory illumination. Unfortunately instead of improving the illumination the experiments generally result in increased glare and consequently increased eye-strain.

A more modern office lighting is by general illumination, produced by larger units installed near the ceiling and so arranged as to give even illumination. Where work is sufficiently concentrated this method of illumination is cheaper to install and operate. A fine appearing installation can be produced, which will not clutter up the room and will not suggest interference on the part of the employés.

In making such an installation it is advisable to use considerable care in selecting the unit so as to produce a satisfactory result. The light source should be of low intrinsic brilliancy, with a relatively large diffusing surface in order to avoid glare, and dense contrasting shadows. The lamp should be economical to operate, and should distribute the light so as to produce an approximately even intensity of illumination in all parts of the room.

The capacity of the unit should be as large as possible, consistent with an even distribution. In a large room with a high ceiling a relatively large unit may be used. A number of different arc and incandescent lamp combinations are available for this class of lighting. The equipment most suitable for a particular case frequently depends upon local conditions.

A representative installation in which an excellent illumination is produced by means of the ceiling diffuser arc lighting system is in the offices of the Stanley Works, manufacturers of builders' hardware, at New Britain, Ct. This company completed a new office building in the late summer of 1907. The artificial lighting of the large general office was planned by the illuminating engineering department of the General Electric Company in coöperation with the architects and the purchasing department of the Stanley Works.

The room in question has a twenty-two-foot stud. The working area is eighty-two feet by seventy-five feet and is lighted by means of twenty-four six-ampere, direct-current enclosed arc lamps, with the recessed type of ceiling diffusers, consuming 15.8 kilowatts.

The lighting has been in service throughout the dark winter months and has given entire satisfaction to both the company and the employés. The excellent illumination of the office, both by daylight and artificial light, is illustrated by the accompanying photographs, which were made under the regular lighting conditions, without flash light or any special treatment.

New Ohio Law Is Valid.

The Ohio state initiative and referendum law has been held constitutional by Judge Chapman in the Common Pleas Court. The test case will be carried to the state Supreme Court, however, for a final decision. The suit was brought after an effort was made to have a vote taken on the franchise granted by the Cleveland city council to the Municipal Traction Company. An election has been ordered by the city council. The law was passed by the legislature last winter.

Electrical Notes from Great Britain.

(From Our British Correspondent.)

IN April last a fire occurred in one of the carriages of an electric train on the Liverpool-Southport Railway just after departure from the Freshfield station. A. P. Trotter, the electrical adviser to the board of trade, has just issued a full report on the occurrence. He divides the cause of the primary fire into two considerations: (1) A short-circuit from a positive cable to the underframe of the carriage; (2) the persistence of the current after it had been automatically cut off. The latter he regards as serious. It was impossible to ascertain the exact nature of the defect which resulted in the short-circuit. Mr. Trotter makes the suggestion that in the construction of new rolling stock, greater care be exercised in protecting cables against the weather so that short-circuits due to water or snow may be avoided. To prevent the persistence of the current, he recommends that each section should have its own feeders, circuit-breakers, etc.

T. O. Callender on July 14 told a sorry tale concerning the variety of unforeseen difficulties that have arisen during the last few years to hinder the progress of the Lancashire Electric Power Company. The generating station, which has a supply capacity of 12,000 horse-power, is at present drawn on only to the tune of 4,000 horse-power, and a considerable part of this is being at present supplied at a loss financially, because there was no practical data available to guide as to correct price for this particular consumer, and the experience has had to be bought. When this contract expires, as it will do in a year, it will be renewed at a higher figure, the consumer having agreed to that course rather than be without the company's supply. Difficulties attending negotiations with municipal authorities in its area for permission to supply energy, have involved heavy expense and serious delays. Another obstacle to electrical installation progress has been the great boom in the textile trades of Lancashire during several years past. Mill owners have expressed themselves as altogether opposed to stopping their works or slackening their operations for the introduction of electrical driving, a good and necessary improvement as they admitted it to be, while there was so great a demand for their manufactures. Now, however, their trade has become slack, and they are beginning to do what they could not undertake when times were so good. Already the Lancashire Power Company is feeling the benefit, and this fact, together with the present improved relations with municipal authorities, points to a better state of things. The development of the business is now in the hands of the Lancashire Power Construction Company, and Horace F. Parshall has, after special invitation, taken the helm as chairman at $5,000 per annum plus ten per cent on the profits in excess of $100,000 per annum before debenture interest is paid.

For many years past the Institution of Electrical Engineers has occupied other people's premises both for general office and library accommodation, and for halls in which to hold its meetings. It is true that at the Victoria street office there is a room sufficiently large for students' meetings and for some gatherings of the Faraday Society, but for anything larger than these, other engineering societies have lent their halls—chiefly the Institution of Civil Engineers. It has been pretty generally felt for a long while that this was a most undesirable position for so important a body of professional men representative of so progressive a department of engineering science and practice, and in consequence a building fund has been accumulating for years. Many a time expression has been given to the desire that all of the great engineering societies might come together to consider a scheme for a large central engineering building in which all could be housed, but the idea has received little encouragement from those most in a position to help toward its fulfilment. The Institution of Electrical Engineers has now, therefore, with pretty general approval from its members, purchased a lease of seventy-six years of what is described as a very suitable building, or one costing comparatively little to make it adaptable to the needs of the Institution. It is situated on the Victoria Embankment and is known as the Medical Examination Hall. The capital cost is £50,000, plus £6,000 for alterations to theatre, furnishings, etc.

The new premises will not be ready for occupation for a year. It is hoped that part of the expenses will be met by letting portions of the building to other societies. The need that electrical men feel for a meeting place in London at which they can hold intercourse with one another at any time—not merely when the announced meetings are in progress—will be met by the foregoing scheme.

Surface contact tramway traction has had most unfortunate experience in England. We announced some time ago that the London County Council was putting down an experimental section of line to be operated on the "G. B." (Griffiths-Bedell) system in Bow and Aldgate, in the East End. It was hoped that after the practical experience with the system in successful running at Lincoln, it would be possible to provide some parts of London with a service which should cost less to construct and equip than the conduit tramway, and should be free from all the alleged objectionable features of the trolley. This hope, according to the latest information, is not to be realized, for defects which have appeared in the running of the Aldgate cars led to the withdrawal of the latter from service on July 17. It is reported in some quarters that this will probably mean the taking out of the system, and if this turns out to be correct it can hardly fail to be fatal to any extension of surface-contact working in this country, especially coming as it does on the heels of the supersession of the Dolter system at Mexborough by the overhead trolley. The chief trouble at Aldgate seems to have been due to live studs, a defect which has to be avoided at all costs in thoroughfares carrying heavy traffic of all kinds.

The Tramways and Light Railways Association held its annual congress on July 9 and 10 at the Franco-British Exhibition at Shepherd's Bush. The Duke of Argyll welcomed the members and Sir Clifton Robinson, who not long since returned from a tour of inspection of tramways in different parts of the world, gave a lecture on "Tramways of the World." He reviewed the course of events in street-tramcar practice since Train put down his first tramway at Birkenhead in 1860. He thought that British tramways if skilfully managed and conservatively financed ought to have an indefinite period of financial prosperity. This should be cheerful news for electric tramway investors who are reaping anything but an adequate return on their investments at the present time. He set down the following directions in which British tramways are handicapped as compared to other countries: (1) British cars are not permitted to travel fast enough, the average speed being less than ten miles an hour. (2) Our double-deck cars, in general use, cause much delay, particularly at stopping points. This type of car was adopted in order to comply with regulations. (3) Traffic could be handled more successfully on special occasions were the present licensing restrictions regarding passengers removed or amended. Speaking of foreign countries he said that the main obstacle to greater development in eastern cities was the narrowness of the streets—this was particularly noticeable in Tokio, Japan, which city has a network of electric tramways, either in operation or proposed. Wherein British tramways lagged behind other countries, it was not the fault of capitalists or engineers, or business men—legislative restrictions and innate conservatism were the real troubles; but we in England had profited by the experience and mistakes of other countries in the matter of efficient apparatus and plant. Sir Clifton Robinson has had to do with the promotion and engineering of a number of important English trolley lines and he has come to close grips with the manifold problems and difficulties, and his views are those of one who has had exceptional opportunities to study the subject—especially from the private company point of view. Alfred H. Gibbings followed with a paper describing modern forms of tramway rail-joints, and the methods which were now being employed to make the joint in operation as nearly as possible like the rest of the rail. A lecture on "Rail Corrugation," delivered by C. A. Carus Wilson, was the other feature of particular interest at the congress.

There is now proceeding at Olympia an exhibition of mining machinery. It contains many specimens of typical English electrical machinery and apparatus for application in mines, electrically driven equipments being present in all parts of the building. The exhibition is timely in view of the great development that is now taking place in colliery equipment. The Franco-British Machinery Hall, with its electrical exhibit, is now in a complete condition. Arrangements are now being pushed forward rapidly for the electrical exhibition which opens at Manchester about two months hence.

ALBERT H. BRIDGE.

London, July 25.

FUNDAMENTAL CONSIDERATIONS GOVERNING THE DESIGN OF TRANSMISSION-LINE STRUCTURES.[1]

BY D. R. SCHOLES.

Before the work of designing a tower or pole for a given transmission line can proceed, a statement must be made setting forth the loads which the structure should be capable of withstanding. This statement is, in general, based on a forecast of the probable extreme weather conditions which may occur in the vicinity of the line, and also on a prediction as to what accidents will probably occur to the conductors of the line.

There are naturally considerable variations in forecasts of this sort and these variations are due primarily to a lack of accurate data regarding the various factors which enter into the case. The cost of a line is affected very largely by the figures which are selected to represent the probable extreme conditions, and the selection and application of these figures are therefore matters of a great deal of importance. Unfortunately, data on this subject are very meagre, and a rational solution of a problem involving weather conditions and possible accidents is manifestly impracticable. It seems, therefore, that the best guide in selecting figures to represent the probable extreme load conditions is experience with existing transmission-line structures and other structures similar to them.

During the last few years many members of the Institute have had occasion to investigate this subject, in preparing specifications for transmission lines. A discussion referring to experience with these lines and bringing out the ideas of each as to what load conditions should be provided for would be very beneficial. It is hoped that there will be such a discussion following this paper.

Figures must, in general, be selected to represent the forces which may come upon a transmission-line structure as a result of one or more of the following influences:

Wind.
Sleet.
Low temperature.
Accidents, as breaking of cables, etc.

It is also necessary to select a factor or factors of safety for use in connection with these figures, and a prediction must be made as to whether or not loads resulting from two or more of these causes are likely to occur at the same time. Considerations of cost often determine to what extent provision shall be made, in a given line, against such combinations of extreme conditions. In a very important line it may properly be considered desirable to provide strength against a combination of conditions likely to occur only once in a hundred years, whereas in a less important line the possibility of such a chance condition might, with equal propriety, be neglected.

[1] A paper presented at the Annual Convention of the American Institute of Electrical Engineers, Atlantic City, N. J., June 30.

Wind Pressure on Structures—The records of the Weather Bureau are available as an aid in estimating the maximum wind velocity to be expected in a given locality. The relation between wind velocity, however, as indicated by a government anemometer, and the actual pressure in pounds per square foot produced by a wind of that velocity on a cable or on the members of a tower, is by no means definitely known. In fact this relation is so uncertain that the most one can hope to gain from an examination of the weather reports is a general idea as to whether the winds occurring in a given locality are likely to be high or not. The anemometers of the Weather Bureau do not take account of sudden gusts of wind. The published velocities are not accurate, but must be corrected according to a correction table which may be obtained from the Weather Bureau.

The relation between wind velocity and the pressure produced by the wind on a plane surface normal to the direction of the wind is given by the formula,

$M = K\ V^2$, where

M = pressure in pounds per square foot,
V = wind velocity in miles per hour,
and
K = constant.

Experiments in general indicate that the form of this equation is correct, but experiments differ as to the proper value of K. The values given range from 0.0035 to 0.0048. According to tests by the Weather Bureau, K = 0.004, which is probably the most reliable figure there is for K.

Experiments indicate that, in general, higher pressures are to be expected at the top of a tower than near the ground, but little is known as to how the pressure is distributed. There is considerable doubt as to what should properly be considered the exposed area of a structure; it is certain, however, that both faces are not, in general, subject to the same pressure. It is usually considered that a reduction factor of 0.5 should be used in figuring the wind pressure per square foot of projected area of cylindrical surfaces. The wide use which has been given this factor is its principal recommendation.

The purpose of the foregoing remarks on wind pressure is to point out some of the reasons for uncertainty in wind-pressure calculations. In view of these uncertainties it seems necessary to turn to some empirical method for providing against loads due to wind pressure. In bridge work pressures of from thirty to fifty pounds per square foot are commonly assumed, and these pressures are used in connection with factors of safety of from four to six. Structures built to withstand loads calculated in this way are found to be strong enough. How much too strong they are is a matter of conjecture. The usual transmission line can not stand the expense of structures built to bridge specifications. Experience with bridges can not, therefore, be of much help in the present connection.

Steel windmill towers have been in general use for about eighteen years. Such towers are built to withstand wind loads almost exclusively and their use is very widespread. It is known that the provision against wind loads in these structures is not excessive, for there are occasional failures. The windmill tower is, in general, similar to the towers used in transmission lines. The success of a given design of windmill tower depends on what might be called the integrated experience of all the users of towers of such design. Competition has led builders to reduce their weight to a minimum. It is probable, therefore, that a windmill tower of standard design which is widely used has just about enough strength to resist the highest winds, tornadoes excepted, and it would appear that a study of such a windmill tower will probably give the best data available for use in connection with transmission-line structures.

An examination of a standard design of windmill tower, of which many thousands are in use, shows that such tower will actually fail under loads calculated on the basis of wind pressures of from forty to fifty pounds per square foot. The tower referred to is of square pyramidal form, and in the calculations it is assumed that the wind is blowing at right angles to one side, and both faces of the tower are considered equally exposed.

It appears, therefore, that it would be good practice in transmission-line construction to specify that the poles or towers should, in addition to their other properties, have strength to resist loads on their members due to a wind pressure of forty pounds per square foot, with a factor of safety of from 1.5 to two, based on actual test. Such a structure would be suitable for locations where the winds are high; in other locations these figures would be reduced by judgment, aided by a consultation of the weather reports and other such data.

Factor of Safety—A few remarks regarding factor of safety may be proper at this point. The factor of safety used in connection with the design of a given piece of engineering apparatus, is, in a sense, a measure of the uncertainty attending the making of calculations of the loads to be sustained or of the strength of the structure under consideration. In designing a complicated structure to sustain a complex system of loads it would be natural and proper to allow a large factor of safety, particularly if the structure were such that it could not be tested to destruction to check all calculations and methods. On the other hand, a smaller factor of safety would be equally safe in connection with a simple structure to sustain certain definite loads, the actual ultimate strength of the structure having been determined by testing it to destruction.

The structures ordinarily used in transmission lines are simple. They are usually built in large numbers from standard designs. It is proper, therefore, that the design for such a structure should be carefully investigated and that specimen structures should be tested in such a way as to remove all doubt as to their ability to withstand the loads for which they are intended. And, notwithstanding the fact that calculations of wind pressure are uncertain, experience with windmill towers removes, to a large extent, the uncertainty which would otherwise surround the figure forty pounds per square foot which has been suggested.

Wind Pressure on Cables—The opinion is commonly held that, in providing against wind pressure on a surface such as that of a long span transmission-line cable, it is not necessary to allow for as high a pressure as is necessary for a surface extending through smaller linear distances. Data on this subject are, as yet, very indefinite, and there is great need of specific figures for the pressure experienced on the cables of a transmission line. The following experiment is suggested as a means of securing such data:

The experimental apparatus would consist of a typical transmission-line span of from 500 to 1,000 feet, erected as near as possible to a Weather Bureau station. The cable would be fixed to the tower at one end and would pass over a pulley at its other end and be secured to a weight, this weight serving to maintain a uniform tension in the cable at all times. The position of the weight would be recorded at all times by means of a pencil and moving drum. Continuous records of temperature and wind velocity are made in the Weather Bureau stations. An analysis of the three records, namely, those of temperature, wind velocity and the length of the cable in the span, would give data from which the wind pressure in pounds per square foot of projected area of the cable could be calculated. It would also be desirable to have a continuous record of the direction of wind, and this record could be readily obtained.

Records from such apparatus extending over a period of a year or more would be of much interest. It is to be observed that the readings would furnish a means of checking the coefficient of expansion of the cable. Data obtained in this way would have direct relation with the Weather Bureau reports, and most questions as to methods of calculation of pressure on conductors would thus be eliminated.

In the absence of specific data relating to wind pressures on the cables of long spans, it seems unsafe to assume a pressure of less than thirty pounds per square foot for localities where the winds are known to be high. The figure thirty pounds per square foot is commonly used in bridge calculations for surfaces extending through horizontal distances of sixty feet or more. It seems that a factor of safety of two should be used in connection with this pressure, so that the conductor will not be stressed beyond its elastic limit, under extreme conditions.

Sleet—Destructive sleet storms occur in the eastern part of the United States at least as far south as Atlanta. During the past winter a sleet storm occurred in the region of Chicago after which a coating of ice over half an inch thick was observed on conductors of various sizes. In many cases the thickness of ice at the centre of the span was much greater than at the insulators, due to the tendency of the water in the sleet to run down to the lowest point while freezing. The sleet formed during this storm was practically solid ice, and it remained on the conductors for several days. In view of observations made after this storm, it is the writer's opinion that, for localities where sleet is known to form, provision should be made against a coating of ice on the cables at least one-half inch thick, in combination with a factor of safety of not less than two based on the ultimate strength of the conductor.

There is much discussion as to whether the safety of a line demands that provision be made against sleet, low temperature, and high wind all occurring at the same time. If the sleet forms at all, it is certainly possible that it will remain on the wires several days. And if it remains on the wires several days it is certainly entirely within the range of possibility that high wind or low temperature, or both, will occur before it melts off. Whether or not provision should be made against a combination of these three extreme conditions becomes, therefore, entirely a question of how much the owners of the line are willing to pay for immunity from interruptions of service due to these causes. These are matters to be settled between the engineer and the owner of the line.

Accidents, as Breaking of Wires, Etc.—In providing mechanical strength in the line to resist loads due to accidents to the cables, there are two well-known plans which may be followed. In the one all structures are given the same strength, each having strength to withstand the loads due to accidents which it is contemplated may occur in any span; in the other plan, two kinds of structures are used—a standard structure intended to support loads transverse to the line only, and a heavy structure having strength against the breaking strength of all the cables. These heavy structures are distributed along the line at intervals of a mile or so. The first-mentioned type of construction is best adapted for lines having relatively small conductors, while the second type is favorable where the conductors are heavy.

In designing a line of the first-mentioned type it is usual to assume that any two conductors may break in a given span due to the formation of an arc between them, and that the tower or pole should be capable of withstanding the loads so developed without damage to itself. Provision is not, in general, made for the simultaneous occurrence of such breakage and high wind or sleet. It would seem, however, that in such cases the towers might be better designed to withstand wind loads transverse to the line in addition to the loads due to the breakage of any two conductors, since arcing is more likely to occur in a high wind than at other times.

It is believed that the factor of safety used in connection with the loads due to breakage of conductors should be greater in the case of suspension type insulators than with pin insulators. When a conductor supported by suspension insulators breaks, it will suddenly move away from the point of breakage and will be brought to a sudden stop when the insulator comes into line with the cable. The movement will occur, in decreasing amount, all along the line or until the strain insulator is reached. This sudden application of load and the attending inertia effect will subject the cross-arm to a greater force than the tension which existed in the cable before it broke. It is suggested that cross-arms be tested to loads equal to 1.25 times the elastic limit of the conductor for pin insulators and 1.5 times the elastic limit of the conductor for suspension insulators.

Foundations—It is a usual assumption that the resistance to uplift offered by a foundation is equal to the weight of the foundation plus the weight of earth contained in the frustum indicated in Fig. 1, the angle of inclination of the sides of the frustum being thirty degrees. The results obtained by this method agree quite closely with practice in anchors for windmill towers. In addition to resisting uplift, the foundation must, in general, have strength against horizontal forces at the ground line. The variety of designs of foundations is so great as to make a discussion of them impossible within the limits of this paper. It is suggested that, in developing the design of a foundation for a given line, tests should be made to determine the holding power, density, etc., of the soil of the locality so that the strength of the foundation will be known as accurately as the strengths of the other parts of the line.

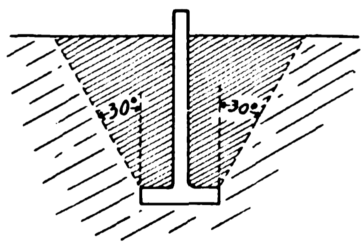

Fig. 1.—Graphical Diagram of Foundation Resistance to Uplift.

Copper Production in 1907.

The Department of the Interior, United States Geological Survey, has issued an advance statement of the country's production of copper in 1907. The output is given as 868,996,491 pounds. This is a decrease of 48,809,491 pounds, or 5.6 per cent, from the record figures of 1906, the largest actual decrease ever recorded and the largest relative decrease since the American copper industry became important. This is the first time since 1901 that the annual production has been smaller than that of the preceding year and the first time since 1872 that it has been smaller than that of the second preceding year.

In the following table the copper production for 1907 is apportioned to the states in which the copper was mined. The total is made up of the fine copper content of blister produced and of the smelter output of ingot and anode copper from Michigan. The production for 1906 is given for comparison:

	1907.	1906.
Alaska	7,034,763	8,685,646
Arizona	256,778,437	262,566,103
California	33,696,602	28,153,202
Colorado	13,998,496	7,427,253
Georgia	....	17,182
Idaho	9,707,299	8,578,046
Massachusetts	....	9,744
Michigan	219,131,503	229,695,730
Missouri	....	54,347
Montana	224,263,789	294,701,252
Nevada	1,998,164	1,090,635
New Mexico	10,140,140	7,099,842
North Carolina	544,040	582,209
Oregon	518,694	545,859
Tennessee	19,475,119	17,809,442
Texas	....	51,377
Utah	66,418,370	50,329,119
Vermont	696,102	11,694
Virginia	57,008	....
Washington	122,263	290,823
Wyoming	3,026,004	106,177
Alabama, Georgia and Maryland	90,655	....
Missouri and unapportioned	1,299,043	....
Total	868,996,491	917,805,682

Of this quantity, approximately 10,075,048 pounds in blister were produced in foreign smelters from domestic materials exported. In addition to the domestic materials handled, smelters in this country turned out as blister 64,145,648 pounds from foreign ore, concentrates, and matte. Domestic blister containing 42,350,963 pounds was exported unrefined, while blister from foreign sources containing approximately 183,530,132 pounds fine copper was imported for refining in this country.

The production in 1907 of refined new copper of domestic origin was 784,271,427 pounds, a decrease of 103,410,960 pounds, or 13.2 per cent, from the production of 1906. The total output of refined copper (exclusive of domestic scrap, etc.) by domestic refineries in 1907 was 1,032,516,247 pounds.

Returns from all the Lake and electrolytic refineries are practically complete and show that the following stocks of refined copper were on hand at the beginning and end of the year:

	Pounds.
January 1, 1908	125,745,796
January 1, 1907	46,497,181
Stocks increased during 1907	79,248,615

Undelivered sales are almost entirely excluded from these figures. Stocks carried by consumers and brokers have not been estimated. In addition to these stocks of refined copper, there were at smelters, in transit to the refineries, and at the refineries blister copper and material in process of refining to the amount of 135,310,239 pounds on January 1, 1907, and of 175,254,659 pounds on January 1, 1908.

The apparent consumption of refined new copper in the United States in 1907 was about 485,000,000 pounds, as compared with about 685,000,000 pounds in 1906. One method of deriving these figures is based on the total refinery output.

American Electrochemical Society.

At a recent meeting of the board of directors of the American Electrochemical Society the previous action of the board in regard to the new class of subscribers, to be called "junior associates," was amended to read as follows: "Students in high schools, technical schools, colleges or universities, or assistants in technical laboratories, furnishing references of good character from their professors or employers, subject to the approval of the board of directors, may, by the payment of the annual dues, without entrance fee, become affiliated with the American Electrochemical Society as 'junior associates.' They will be printed as such on the roll of the society, will receive the transactions, the monthly bulletin and other notices of the society, may attend meetings, offer papers, take part in the discussions of papers and participate in visiting and social functions; but they do not have the right to hold office, vote for officers, or vote on or discuss business motions brought before the society. The said 'junior associates' may remain as such not over five years after their first enrollment and may become members at any time by being regularly elected by the board of directors and paying the entrance fee."

At the same meeting of the board the committee appointed to draw up the regulations governing the competition for the award of the Pacific Coast Borax Company's prize of $500 reported. This committee consists of Alois von Isakovics, Dr. E. F. Roeber and Dr. Leo Baekeland. Their recommendations are as follows:

The sum of $500 has been paid to the American Electrochemical Society, and deposited in trust, as a research fund, to be awarded as a prize, under the following conditions:

The Pacific Coast Borax Company desires to awaken an interest in research work and experiments which may lead to some improvement in the commercial method of manufacturing ferro-boron, by a direct process from Colemanite.

It is essential that the process should be sufficiently economical and suitable to be applied on a large scale, so that the finished product may be available for commercial purposes. (Commercial ferro-boron, as now made, contains twenty per cent or more of boron, less than three per cent of carbon, and sulphur and phosphorus are practically absent.)

The prize has been deposited with the American Electrochemical Society, with the request that the board of directors award the same for the best practical solution of the problem, under reasonable conditions, to be decided upon by the board of directors.

In accordance with the above request, competitors for the prize are notified that they must comply with the following conditions:

1. The treatise on the subject must be in typewritten form and accompanied by a sample produced by the process described in same.

2. The competition for the prize is open to any one and is not restricted to members of this society. The treatise on the subject must be enclosed in a plain, sealed envelope, not bearing the author's name, but identified by a pseudonym. The outside of the envelope containing the paper must be labeled with the pseudonym and with it should be sent another plain, sealed envelope, also labeled with the same pseudonym, which should contain inside the envelope the name and address of the competitor. Both these envelopes should be sent to Professor Morris Loeb, 273 Madison avenue, New York city.

3. All papers competing for the prize must be in the hands of Professor Loeb before October 1, 1909. Professor Loeb shall retain the small sealed envelope containing the address of the competitor and forward the large envelope containing the treatise, as well as the sample of the product, both merely labeled with the pseudonym, under cover, to the secretary of the American Electrochemical Society, to be submitted to the board of directors who will award the prize. In this manner, as the treatise must be typewritten, the board can act with entire impartiality and the paper shall be judged on its own merits so that the author's standing can have no influence whatever on the decision. The competitors for the prize forfeit none of their property rights in the process submitted.

4. As soon as the board of directors has agreed upon the best treatise, it will request from Professor Loeb the address of the author thereof, who will then be required to demonstrate his process before the prize will be finally awarded.

5. The Pacific Coast Borax Company, 100 William street, New York city, has offered to supply any one who desires to compete for the prize seriously with all the crude Colemanite that the parties making the experiment may require, provided that the request for this Colemanite be accompanied by a letter signed by one member of the board of directors of the American Electrochemical Society, endorsing the application for the material. This condition is merely made so as to furnish the material only to those who may have the proper qualifications to experiment intelligently and with some chance of success.

For the convenience of competitors who may desire to consult some of the published literature on the subject, a brief bibliography is herewith attached:

H. Moissan and G. Charpy, Sur l'acier au bore, Comptes Rendus, 1895, vol. cxx, p. 130.

M. L. Guillet, Les aciers au bore, Revue de Metallurgie, August, 1907, vol. iv, pp. 784 to 796 (translated in abstract in "Electrochemical and Metallurgical Industry," 1907, vol. v, p. 421).

A bibliography on boron and borides in general may be found in O. P. Watts, "An Investigation of the Borides and Silicides," Bulletin University of Wisconsin, No. 145 (Engineering Series, vol. iii, No. 3, 1906).

As previously announced the fourteenth general meeting of the society will be held in New York, October 31, at the Chemists' Club, 108 West Fifty-fifth street. The invitation of President Acheson to hold the fifteenth annual meeting at Niagara Falls, Ontario, May 6, 7, 8, 1909, was accepted. Headquarters will be at the Clifton House.

Commission Opposed to Central Express Company.

In denying the application of the Interurban Express Company, Syracuse, N. Y., for permission to exercise rights as an express company on certain railroads in and near Syracuse, the Public Service Commission, Second District, lays down the rule that an operating railway or trolley company should not be permitted to divest itself in favor of another corporation of the obligation to perform any of the public services for which it is incorporated unless it can show clearly that public necessity so demands or public convenience can be better served thereby.

The company in question was organized as an express company to do an express business from and to any points in the United States or otherwise by means of electric cars and vehicles, horses, wagons, boats or other means of transportation. The application to the commission was made particularly in connection with the interurban and electric roads controlled by the so-called Bebe Syndicate, namely, the Auburn & Syracuse Electric Railroad Company, the Rochester, Syracuse & Eastern Electric Railroad Company, the Syracuse & South Bay Electric Railroad Company, the Syracuse, Lake Shore & Northern Railroad Company and the Auburn & Northern Electric Railroad Company.

Under the Public Service Commission's law the company can not do business without the consent of the commission. The opinion written by Commissioner Osborne among other things says that the advantages claimed by the service applied for can be easily secured by the trolley companies themselves without the formation of a central express company. He urges against the granting of the application the duplication of companies whereby the public would pay directly to the express company for carrying the package and would also pay indirectly to the railroad company for the use of its tracks in carrying the same package, and the cost to the public is certainly increased by the addition of the extra company.

Some Interesting Advertising Literature from Central Stations.

The Commonwealth Edison Company, Chicago, Ill., has long been famous for the attractive quality of its advertising literature. Dana H. Howard, manager of the advertising department of this company, has introduced some of the most novel ideas which have come to our notice, and the department is one of the most successful in the field. The accompanying illustrations show some of the newest ideas which Mr. Howard has evolved. The series of postal cards showing the various uses of electrical devices, such as toasting irons, chafing dishes, desk lamps, flat-irons, electric fans and coffee percolators, is very handsome and has attracted a great deal of favorable comment. These cards are all photographic reproductions of the highest grade of postal-card souvenir. Another card which the company is making good use of is the assignment card, an illustration of which is shown herewith. This series includes references to closet lighting, the nursery milk-warmer, the electric corn-popper, the electric chafing dish, and the electric waffle iron. The card is printed in brown and red.

A Beautiful Series of Postal Cards from the Commonwealth Edison Company, Chicago, Ill.

The company has recently published a vest-pocket catalogue of electrical devices for use in the home. This illustrates and describes the electric chafing dish, the electric fan, electric curling-iron heaters, electric flat-irons, the electric coffee percolator, the electric toaster, and gives several recipes for use with the electric chafing dish. Still another illustration is a reproduction of a large-sized lithograph which the company is displaying in department stores, drug stores, stationers, and in all public places.

An Attractive Lithograph in Bright Colors Used by the Commonwealth Edison Company, Chicago, Ill.

The Denver Gas and Electric Company is keeping up its good publicity work, one of its most recent ideas being the distribution of a fine series of postal cards in connection with the Democratic National Convention. The accompanying illustration shows the mammoth electric sign which was used on this occasion, and which has been reproduced and commented upon in the daily papers throughout the entire West. This electric sign was easily the hit of the decorative features of the convention, and impressed the visitors with the ingenuity and availability of the electric sign as a means of attracting attention.

The Commonwealth Edison Company has its mains in this vicinity and is prepared to furnish you with

Electricity for Lighting, Heating and Power Purposes

at unusually reasonable rates.

The Electric current, which supplies the most sanitary light, is used also now-a-days for heating, cooking and small power purposes in the home. There are Electric Fans, Flat Irons, Chafing Dishes, Coffee Percolators, Heating Pads, Water Heaters, Curling Iron Heaters, Toasters, all operated by electricity at small expense.

Our representative will call upon you if you will mail this card, properly filled out. You are not obligated thereby.

REVIEWS OF CURRENT ENGINEERING AND SCIENTIFIC LITERATURE

Absorption of X-Rays.

Probably all elements when subjected to a suitable primary beam become sources of homogeneous Roentgen radiation which is characteristic of the element emitting it. These radiations have been studied by C. G. Barkla and C. A. Sadler, who here give some of their conclusions. When a very absorbable primary radiation is incident on a given element, the homogeneous radiation characteristic of that element is not emitted in appreciable intensity. As the penetrating power of the primary radiation is increased, the absorption decreases only up to a certain point. When the penetrating power becomes greater than that of the radiation characteristic of the absorbing element the absorption of the primary radiation begins to increase and a secondary homogeneous radiation begins to be emitted. Then there is a rapid and considerable increase in both the absorption of the primary rays and in the emission of the secondary rays. When the general penetrating power is increased still further, the absorption decreases again in the usual way, and the intensity of radiation decreases at the same rate as the ionization produced by the primary beam in air. Experiments have not been made to determine if all the extra energy absorbed appears as energy of secondary radiation; but from observations of the absorbability of the secondary radiation and of the ionization it produces, it appears probable that a large proportion is re-emitted. The emergent radiation is a mixture of two homogeneous radiations, the proportions of which depend primarily on the coefficients of the absorption of the incident radiation and of the radiation characteristic of the metal in the metal itself, and the coefficient of the transmission of one into the other type of radiation and the thickness of the absorbing plate. The following is given as a more precise statement of the special power of a homogeneous radiation of penetrating the element emitting it than has previously been given: A radiation which is more absorbable, equally absorbable, or only slightly more penetrating to most substances than the radiation characteristic of the element upon which it is incident, is absorbed much less than one of more penetrating type. It also produces little or none of the characteristic secondary radiation which is produced by the more penetrating radiation.—*Abstracted from Nature (London), July 16.*

On Some Methods of Measuring Capacity with Alternating Currents of Complex Wave Forms.

A quick and convenient method of determining capacity is to measure the current flowing when a sinusoidal electromotive force of known value is applied. But if the wave form departs from a pure sine wave, the ordinary method can not be used without certain precautions. In this article, Robert Beattie describes a number of methods of measuring capacity accurately, which are not affected by the form of the electromotive-force wave. The first of these to be described is the use of a "swamping" resistance placed in series with the condenser under test. If this resistance is so large when compared with the reactance of the condenser that the former determines the magnitude of the current flowing, the capacity may then be measured with an accuracy of a few per cent irrespective of the wave form. Without the "swamping" resistance an irregular wave form might introduce an error of from thirty to forty per cent. If there is any doubt of the adequacy of the swamping resistance, a swamping inductance may be used. The resistance of this must be negligible, and when this is the case the reactance is more effective than a swamping resistance. With this method it is not difficult to measure the capacity accurately within one per cent. If a known capacity be available, the unknown may be compared directly with this, and since the irregularities of the electromotive force affect both to a similar degree, no error will be introduced. In the same way the capacity may be measured by connecting the condenser in series with a known inductance. Rowland in 1898 described a number of zero methods of measuring capacity by means of alternating currents, but did not point out that when these zero methods are used the result is independent of the wave form. Deflectional methods may also be employed, if, instead of measuring merely the current and the electromotive force, the power is also measured. To indicate the value of these different methods, the results of a series of experiments on a single condenser with a wave form of very irregular shape are given. With the simple current and electromotive-force measurements the capacity was apparently twice as much as it was known to be. By placing a swamping resistance in series, the result was within two per cent of the known value. With a swamping inductance the discrepancy was within the limits of experimental error, and the same accuracy was obtained when applying the other methods referred to. — *Abstracted from the Electrician (London), July 17.*

Electricity Supply in Sutton (Surrey,) England.

A brief description is given here of the new electric supply station of the township of Sutton, which lies just outside of the southwestern boundary of the County of London, England. This installation is interesting because of the methods adopted to avoid vibration and noise. The original equipment consisted of alternators direct-connected to reciprocating engines. This gave rise to so much trouble with surrounding householders, through vibration and noise, that the company decided upon the adoption of a steam-turbine plant. This decision was reached after a number of attempts had been made to stop the vibration. One of these consisted in digging a trench thirty feet deep around the edge of the company's land, but this had no appreciable effect. The station stands on solid chalk, as does also private property 100 yards away. The new generating equipment consists of three 500-kilowatt turbines, each coupled to a 250-kilowatt direct-current generator and a 250-kilowatt alternator placed in tandem. Each machine has also an exciter mounted on the end of the shaft. The units run at 3,000 revolutions per minute, and supply fifty-cycle, single-phase current at 2,200 volts alternating, and direct current at 550 volts. The units are mounted on a ferro-concrete pad eighteen inches thick, which in turn is supported on fourteen groups of rubber pads on the Prache system, each group consisting of seven pads carried on a circular cast-iron tray mounted on a concrete pillar which forms the fixed foundation. This arrangement is said to be entirely satisfactory in damping down the vibration. Another interesting feature of this plant is the use of a Raworth cutout on the switchboard. This is necessary since a part of the direct-current output is used for electric railway purposes where the Raworth regenerative system of operation has been adopted. The cutout is a reverse-current breaker which disconnects the feeder when the incoming regenerated current from the car exceeds that sent out by the station.—*Abstracted from the Electrical Review (London), July 17.*

The Economical Aspects of Wood Preservation for Structural Purposes.

There has been more or less discussion during recent years on the value of the various processes of treating wood with a view to preventing decay. However, a good deal of uncertainty still exists respecting the economical value of such treatment. In this article C. P. Winslow discusses the subject from this point of view. After pointing out the enormous consumption of timber of all sorts, which exceeds three times the annual growth of the forests in this country, he emphasizes the necessity for reducing the annual cut of wood, and says that the only apparent method of relieving the situation is some treatment of the timber which will protect it against decay. To be successful, the process employed must reduce the cost of the timber to the consumer; but in determining this cost the effect of the reduction in price due to the reduced cut, as well as the cost of replacement, must be considered. Such a system should render durable the soft woods which to-day can not be used where exposed to the weather. It has already been shown that the life of timber may be doubled by the use of cheap preservatives; and by using a more expensive treatment, the life can be still further prolonged. In applying such treatment on a large scale the additional cost will seldom exceed the present price of the lumber. This cost may then be set off against the cost of replacing the material and the increase in price which would have taken place had the drain on the forests continued at its present increasing rate. During the past five years the cost of mining timbers in the West has increased forty to fifty per cent, and a corresponding increase may be expected during the next five years, if no relief be secured. To show more specifically what the effect of treatment might be, consider the railway tie situation. During 1906 about 103,000,000 ties were purchased, these being in general oak, cedar and chestnut. Oak formerly was the most largely used wood, but the cost of oak ties has doubled in the past ten years, so that other woods are now being taken. It has been estimated that on an important western road the average cost of untreated hemlock is about seventy-five cents a tie; the cost of a satisfactory treatment with zinc chloride is about twelve cents a tie, raising the cost of the treated tie to eighty-seven cents. If the untreated tie last five years, and interest be allowed at four per cent, the annual charge on this tie would be 16.8 cents. If the treated tie last but a single year longer, the annual charge is lowered to 16.6 cents, while if it last ten years, the annual charge is 10.7 cents. By the substitution of creosote for zinc chloride, with some increase in the cost of treatment, the ties can be counted upon to resist decay for twenty years. It is of no use, however, to give a tie a length of life as long as this, if its mechanical life is but ten years; so that screw spikes and tie plates would become advisable when the more expensive processes of treatment are used. To take another instance, during the year 1906, nearly 3,600,000 poles were cut for telephone, telegraph and electric power lines. The average value of these poles at the point of purchase was $2.65. As these poles come from a limited section of the country, the cost of transportation often equals the initial cost at the point of purchase. All these poles must be renewed within fifteen years; and as the supply of cedar and chestnut, the woods principally used for poles, is becoming exhausted, a substitute must be found which may be treated so as to give it a satisfactory life. A thirty-five-foot loblolly pine may be purchased, hauled and set for five dollars; so that allowing interest at five per cent, the annual charge becomes $1.15. A pole of this sort may be given a satisfactory butt treatment with creosote for one dollar and unless set in very unfavorable conditions will have a life of twenty years. The annual charge is thus reduced to forty-eight cents, a yearly saving of sixty-seven cents a pole. These two instances demonstrate the economical value of a preservative treatment when properly applied. Several other examples are given, applying to other lines of construction, all of which show that whenever timbers are to be placed for permanent use under conditions favorable to decay, or where a subsequent replacement would entail heavy charges, a thorough preservative treatment of the best quality is recommended. Frequently when a company is using large quantities of timber the establishment of a treating plant will soon repay the cost of investment.—*Abstracted from the Engineering Magazine (New York), August.*

High-Speed Electric Elevators.

During a discussion on traction elevators before the Western Society of Engineers, John W. Mabbs described the high-speed electric elevators now in service in the Chicago Board of Trade Building. The car of the elevator is suspended from one end of the system of ropes; the latter are then carried over the overhead sheaves, and down around an idler to which is attached the counterweight, and then up to a fixed point. The counterweight is a self-supporting and self-propelled device; it is worm-geared, and climbs up and down two vertical columns by means of four pinions which engage four racks mounted on the columns. As the motor ascends the racks, the car descends at twice the speed, covering the entire travel while the counterweight travels but half the height of the building. To prevent over-running in either direction, automatic stops are provided at both ends of the travel of the counterweight, and there are also mechanical oil buffers which are sufficient to take care of the machine should the controller and all the automatic stops fail. The speed of the elevator ranges from 540 to 600 feet a minute, though it is said a higher speed may safely be given if desired. These elevators may be reversed at full speed without perceptible pause and without a particular shock or jar. The cars stop more quickly and less disagreeably than hydraulic elevators. One of these elevators has been in constant operation in the Chicago Board of Trade Building for five and a half years, and has been out of service but a single day. Two years ago four more similar elevators were installed in the same building and have been in operation since then, and but one machine has been out of service, and that for only a single day. The repairs on the elevators have averaged less than $85 each a year, while the energy consumed has been 3.54 kilowatt-hours per car mile.—*Abstracted from Journal of the Western Society of Engineers (Chicago), June.*

INDUSTRIAL SECTION

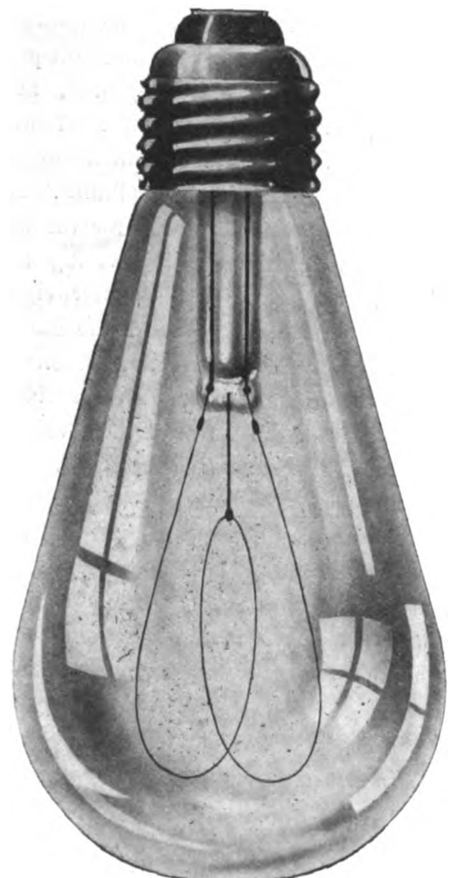
ILLUSTRATED DESCRIPTIONS OF NEW AND STANDARD ELECTRICAL AND MECHANICAL APPARATUS

New Gem and Tungsten Lamps.

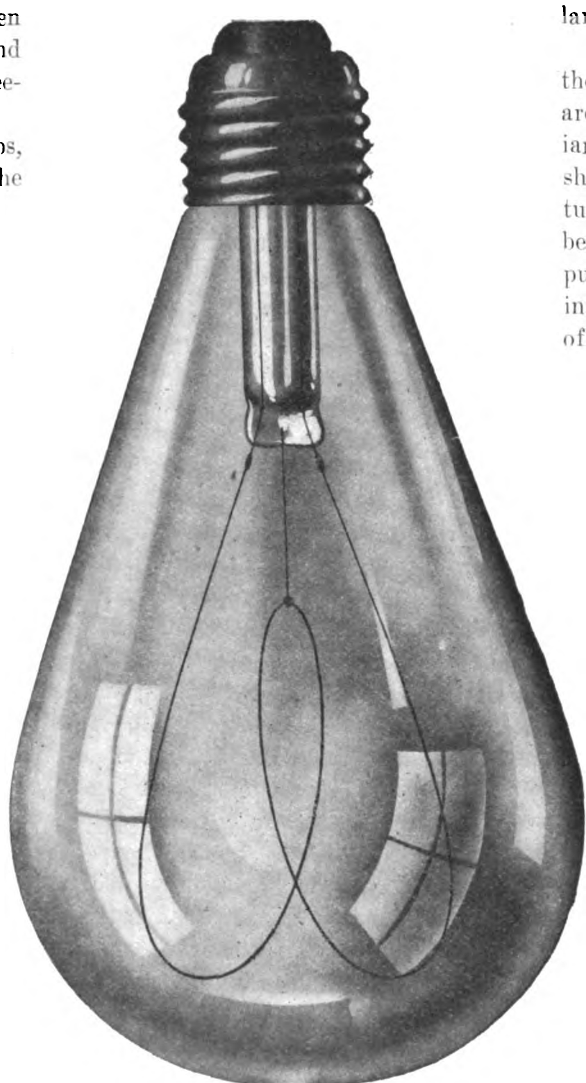
The members of the National Electric Lamp Association are placing upon the market four new types of lamps. Two of these are Gem lamps with oval filaments, all Gem lamps of the same voltages having been heretofore made with two-loop filaments only. Two of these are tungsten Meridian type lamps in the regular round Meridian type bulbs of three and three-quarters-inch and five-inch diameters.

The existing Gem filament type lamps, ninety to 130 volts, are all made in the double-loop type. A great deal of difficulty has been experienced in properly metallizing filaments of other forms and types. This difficulty has been now overcome so far as the oval type is concerned and this type of filament is being employed in the two new Gem lamps now ready for the market.

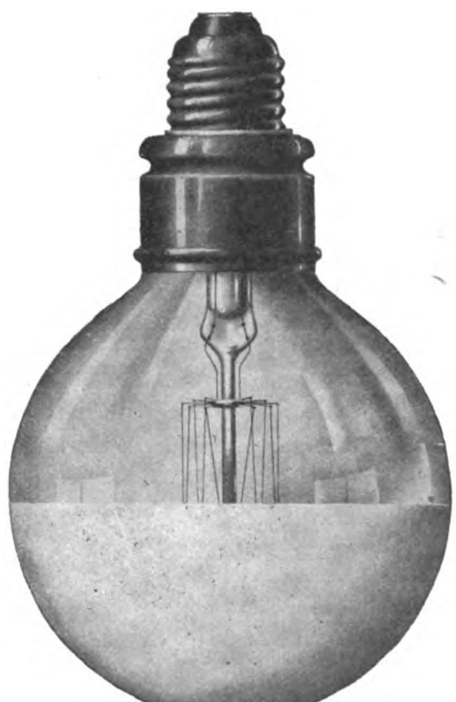
Gem lamps, voltages 90-130, have been made heretofore in the 50, 100, 125, 187 and 250-watt sizes. The two new types are supplementary to the above, are of forty and eighty-watt sizes and are designed for the same voltages, namely, 90-130, as the present Gem lamps. The mean horizontal candle-power of the forty-watt size, therefore, is sixteen candles and of the eighty-watt, thirty-two candles, at two and one-half watts per mean horizontal candle.



Gem Forty-Watt Lamp.



Gem Eighty-Watt Lamp.



Forty-Watt Meridian Tungsten Lamp.

These two lamps are made in bulbs which are standard in the carbon-filament sizes for sixteen and thirty-two-candle-power, respectively. The sixteen-candle-power bulb (the SS 19 bulb) is standard in the Gem fifty-watt size now on the market; consequently, the Gem forty-watt lamp in this size of bulb is similar to the Gem fifty-watt lamp, although dissimilar as above noted, in the type of filament.

The Gem eighty-watt lamp, designed to operate at thirty-two candles at 2.5 watts per candle is made in the bulb (the SS 24 bulb) which is standard in the thirty-two-candle-power carbon type of lamp, and, therefore, so far as cursory inspection goes, this lamp is exactly similar in appearance to the thirty-two-candle-power carbon lamp which it is expected it will largely displace.

Illustrations of these two lamps using the ordinary small standard Edison base are shown herewith. The tungsten Meridian lamps, illustrations of which are also shown herewith, differ from the other tungsten-filament lamps which the members of the National Association have been putting out for these voltages (100-125) in that five filaments are employed instead of four, and in the size and shape of the bulb. Every change in size and shape of the bulb involves new problems in exhaustion and means new apparatus and equipment.

The development of the tungsten lamp in this country has been extremely rapid and the production facilities of the association members have been taxed to supply the demand. The supply, however, of the larger-bulb lamps is now equal to the demand and, inasmuch as these two lamps require somewhat similar manufacturing facilities to the large-bulb lamps, the attention of the staff, which has been devoted to the developing of the larger-bulb tungsten lamps (100-125 watt) has recently been given to equipping for the tungsten Meridian type lamps which are expected to displace the present Meridian type lamps almost universally.

The Meridian type lamps were first placed upon the market with carbon filaments and gave sixteen and thirty-two candles mean horizontal (unfrosted) at sixty and 120 watts, respectively.

SIXTY-WATT MERIDIAN TUNGSTEN LAMP.

With the advent of the Gem filament these same lamps were put upon the market at fifty and 100 watts with an increase in candles (mean hemispherical candle-power, unfrosted) to twenty and forty candles, respectively. It will be noted that these new tungsten lamps give higher candles than any of the preceding types, in the same size of bulb, namely, thirty-two and forty-eight, respectively (mean hemispherical candle-power, clear bulb).

These lamps operate at the same filament temperature that has been adopted for the other types of tungsten lamps, namely, 1.25 watts per candle horizontally.

These tungsten Meridian lamps can be operated at any angle and are designed to give the proper distribution of light with the present Meridian or prismo type reflectors and involve no additional fittings (in the way of sockets, shade-holders, etc., or reflectors), and are made in all voltages from 100 to 125 exactly as are other tungsten-filament lamps.

Data book sheets covering these lamps in detail are in the hands of all members of the National Electric Lamp Association and any further detailed information as to standard package quantities, deliveries, prices, etc., can be furnished by the member companies upon request.

The same life values of the approximate sizes are named for these new lamps.

Sales of Small Curtis Turbines.

The increasing use of small Curtis steam turbines is strikingly shown by an inspection of a partial list of turbines under 500-kilowatt capacity which, up to the present time, have been installed by the General Electric Company or are under construction.

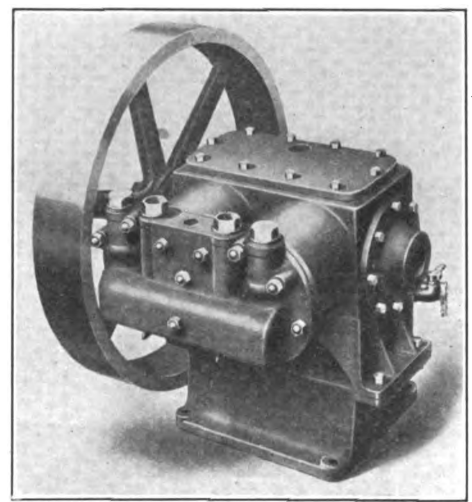
Of the 570 odd turbines listed, representing a total capacity of about 37,000 kilowatts, seven per cent are for the export trade. The remainder are intended for domestic service in central stations, marine work, laboratories of educational institutions, power and lighting plants for hotels and office buildings, laundries, mines, printing establishments and in every branch of manufacturing. It is interesting to note the widely different industries in which small Curtis steam turbines are used. Among the list are woodworking plants, foundries, iron and steel mills, distilleries, chemical plants, ice plants, textile mills, breweries, tanneries, flour mills, shoe factories, paper mills, machine shops, textile mills, and ammunition manufacturing plants.

Turbines for train lighting are finding a ready market and it is interesting to note that the leading railroads are using this method of train illumination. The latest application of moderate size Curtis turbines is for driving fire pumps, in which capacity they have been very satisfactory. On board ship, where a compact generating unit is required, small turbine lighting sets are also rapidly coming into favor.

New Air-Brake Type of Air-Compressor for Industrial Service.

The adaptation of the standard types of air-compressors used with air-brake equipments to many industries requiring compressed air has been decidedly successful. The demand for them has broadened to such an extent that the Westinghouse Traction Brake Company has found it necessary to provide a line of belt-driven compressors similar to their well-known motor-driven compressor for cases where the only power available is from shafting or where it is not expedient to use either steam or electric motive power.

These compressors, designated as the type F-B belt-driven air-compressors, are made in four different sizes, *viz.,* F-1-B, F-2-B, F-3-B and F-4-B, having fifteen, twenty-six, forty-four and one-half and



AIR-BRAKE TYPE OF AIR-COMPRESSOR.

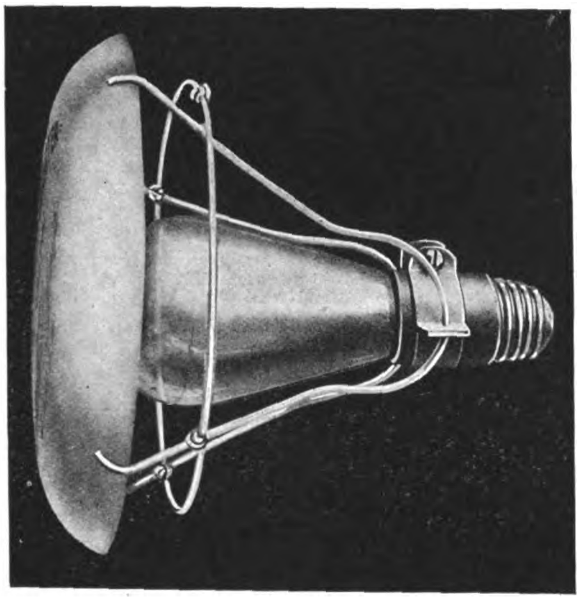
fifty-four and one-half cubic feet of free air per minute capacity, respectively, at the standard speeds, 220 revolutions per minute for the F-1-B and F-2-B, and 200 revolutions per minute for the F-3-B and F-4-B compressors. The horse-power required to operate the compressor in the four different sizes, at 100 pounds pressure, is three, five, nine and eleven respectively.

They will operate successfully against pressures up to 200 pounds per square inch, and may be had with or without water-jacketed air cylinders as occasion requires.

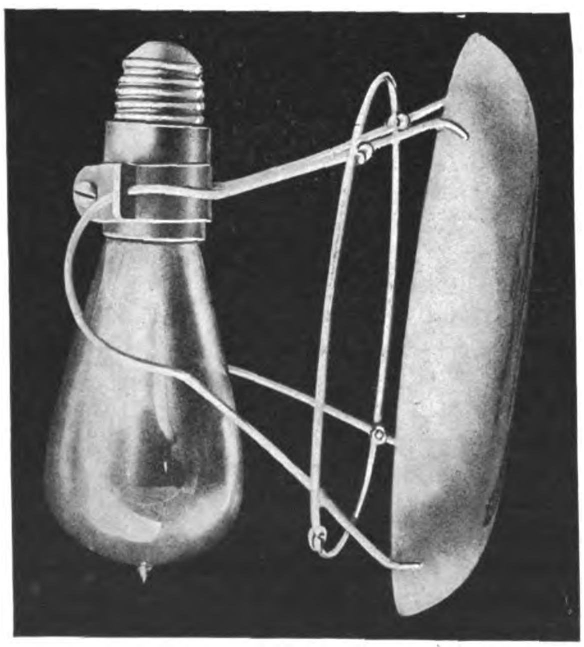
The F-B compressor is most compact in design, being similar in all respects to the motor-driven compressor, except that the motor is replaced by a belt wheel, keyed on the crank-shaft of the compressor. It is of the duplex, horizontal, single-acting type, portable, applicable to any industrial service, and maintained at small cost.

The Phelps Adjustable Sign.

The accompanying illustrations show an adjustable sign which has been developed by the Phelps Manufacturing Company, 54 State street, Detroit, Mich. In designing this sign the aim has been to produce a unique electric sign at a low price. This form of sign is adaptable to every kind of electric fixture, and can be turned to read in any desired direction. As a show-window sign the lamp, while illuminating the sign, also throws light on the goods in the window. It is easy to handle, economical to ship by mail or express, and fits any socket at any angle. The sign is lettered in translucent colors with either raised or surface work.



Phelps Adjustable Sign Placed at End of Lamp Bulb.



Phelps Adjustable Sign Placed Parallel with Lamp Bulb.

Motor-Driven Refrigerating Machinery.

A comparatively new, yet rapidly growing, use to which electric motor drive is applicable is that of the refrigerating outfit. Only those closely connected with the trade realize the varied and extensive use to which these machines are put.

Two years ago motor-driven refrigerating machines were common in residences, dairies, saloons, drug stores, butcher shops, packing houses and hotels. To this list have been added ice cream and candy factories, florists, fish and game markets, hospitals, cold-storage warehouses, tanneries and general office buildings.

The tendency on the part of the public to demand pure, cool drinking water points to the general use of refrigerating machines for cooling drinking water in all public institutions, such as libraries, schools, etc., and in general office buildings. In connection with refrigeration, motor-driven carbonating machines might be suggested. These machines may be installed in drug and confectionery stores for supplying the aerated water used in soda fountains.

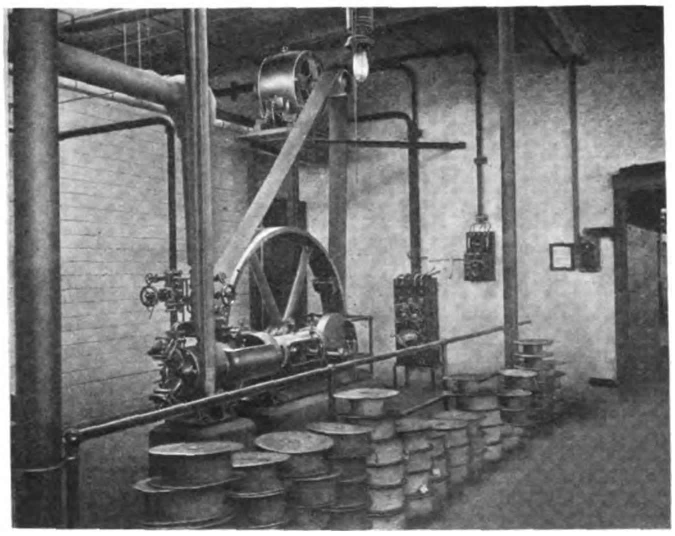


Fig. 1.—Forty-Horse-Power Motor Driving Compressor.

Electric motor drive, besides being in most cases the most economical in operation, is a clean, reliable source of power, and one available at all times. Motor drive, because of its simplicity, can also be readily understood and operated by even the ordinary mechanic. The subject of cleanliness is one not to be overlooked, especially by those engaged in the manufacture of ice cream and candy.

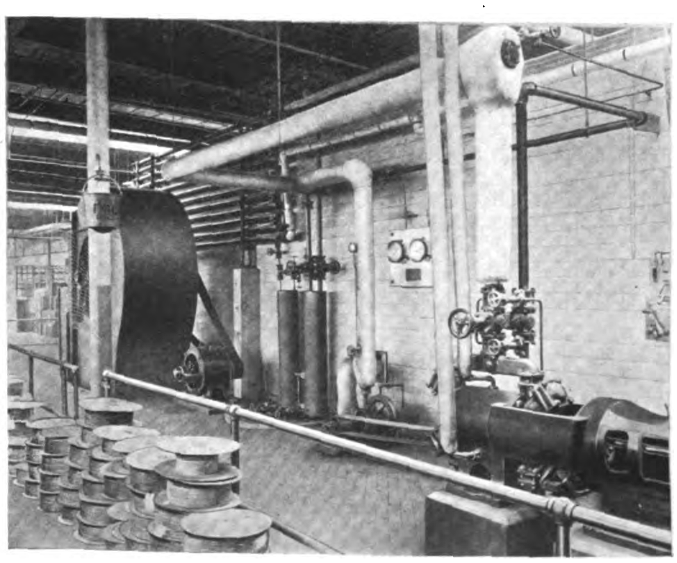

Fig. 2.—Motor-Driven Blower and Centrifugal Pumps.

The cost of electric energy is about one-half that of ice at the present scale of prices, and the owner of a refrigeration plant has no fear of an ice famine. In most cases it is not necessary to operate the plant continuously. This, and the fact that the minimum capacity is required at night and in cool weather, makes it possible for the user of electric energy to keep his machines off the peak load of the station, and thus obtain the lowest kilowatt-hour rate.

The installations in common use vary in size from one-quarter-ton residence outfit to the fifty-ton packing-house plant. In most cases the small machines are belt-connected to motors, and the large machines use silent roller chain drive.

Fig. 1 and Fig. 2 illustrate the equipment of the Western Electric Company's motor-driven refrigerating plant at their Hawthorne works. This equipment, used to cool the rooms of the cable plant during the summer months, acts both as a cooling and ventilating system. The brine circulation system is used exclusively, all expansion coils being located in the brine tanks. The apparatus consists of an ammonia compressor, a cooler containing the brine tanks, a blower and a brine pump.

The compressor, shown in Fig. 1, is driven by a forty-horse-power, direct-current motor, mounted near the ceiling. The compressor, operating in connection with ammonia pipes in the brine tanks, reduces the temperature of the brine, which in turn cools the air in the cooler. These brine tanks are open, and the brine in them is kept in circulation by means of a centrifugal brine pump, driven by an eight-horse-power motor. When the air within the cooler is at the desired temperature, the large exhaust fan, shown in Fig. 2, is started. This fan drives the air through the cooler, where the temperature is lowered, and out into a distributing system. The blower is belt-connected to a twenty-horse-power, direct-current motor. This plant was designed by S. W. Calhoun, consulting engineer, of Chicago, and has a capacity of fifteen tons. The motors used to drive the compressor, brine-circulating pump and fan are all 220-volt, direct-current machines, built by the Western Electric Company.

New Sectional-Gang Conduit Boxes.

The Chicago Fuse Wire and Manufacturing Company, 170 South Clinton street, Chicago, is placing on the market a new conduit box, No. 160, embodying the sectional-gang idea employed in its well-known type "AA" and "BB" boxes for flexible conduit. A box for any number of gang switches can be built up from a two-gang box shown in Fig. 1, by loosening the screws and inserting spacers, the box and cover part of the spacer being formed of one piece, the only detachable part on top being the small end-cover plates which may be removed without taking out a screw, permitting ready access to the bushings of end conduits, also allowing examination of wires without disturbing switches.

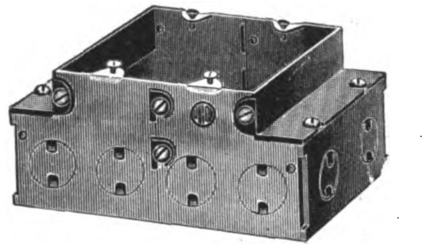

Fig. 1.—Two-Gang Box.

Fig. 2 shows a three-gang box with spacer in place, the hook-eye construction enabling these boxes to be assembled without removing a single screw, forming a perfectly tight box, meeting in every detail the requirements of underwriters, as well as filling a long-felt want of electrical contractors for a sectional-gang conduit box in which there is ample room for conduit connections, wire joints, etc. This box makes an ideal junction box when equipped with a flat cover, and is particularly suitable as a cutout box, being designed to accommodate the single and double-pole main line blocks and also several single and double-branch cutouts manufactured by this company.

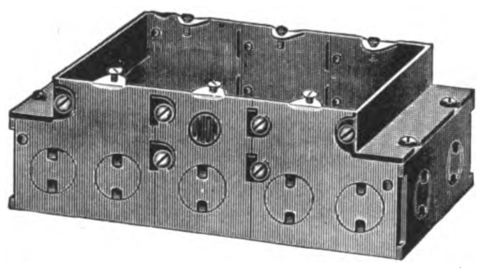

Fig. 2.—Three-Gang Box.

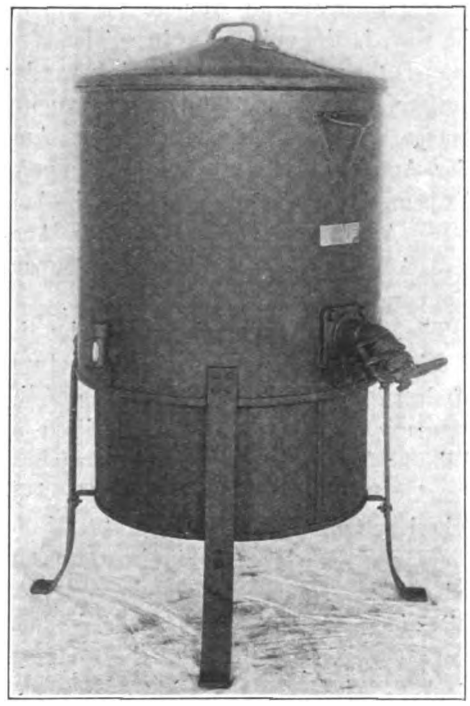
Each spacer is provided with two knockout plugs for one-half-inch or three-quarters-inch conduit as specified, while each box portion is equipped with six such openings.

The spacings between switch-lug centres are standard so that all gang-switch plates fit perfectly. The advantage of this construction over the single-piece gang boxes must appeal at once to every user of conduit boxes, as it enables him to meet any demand for gang boxes with only a stock of two-gang boxes and spacers.

Glue Cookers.

The accompanying illustration shows a ten-gallon glue cooker shipped to the J. B. Lyon Company, Albany, N. Y., by the Westinghouse Electric and Manufacturing Company. The Westinghouse company builds a line of these cookers ranging from five to twenty-five gallons in capacity, and they are used by the manufacturers of printing press rollers, bookbinders and large cabinet work shops where it is necessary to melt and keep in working condition large quantities of glue or other compositions for replenishing the smaller glue pots used on the bench. These glue cookers are arranged with two heats, a high heat for melting down raw stock, and a low heat for holding the stock at a working consistency.



Electrically Heated Glue Cooker.

A New Seamless Trolley Pole.

A new seamless trolley pole is being put on the market by the R. D. Nuttall Company, Pittsburg, Pa. It is made of cold-drawn seamless tubing of the highest grade to be obtained.

Great strength is insured by a reinforcement at the bottom and a gradual taper at the top. The reinforcement is sixteen and one-half inches long and made of the same material as the pole proper. It is inserted cold and with such care as to fit that it practically becomes a part of the pole.

The taper begins three feet from the top and reduces the diameter from one and one-half inches at this point to one inch at the end. This gives to the pole great strength and rigidity.

The pole is made in all lengths up to eighteen feet and combines rigidity with light weight. The average weight of the twelve-foot poles is twenty-two pounds.

The Crocker-Wheeler Company and Ampere.

The island now known as Manhattan has had at various times forty-six different names applied to it, ranging from Manetto and Manath to Munhaddons. The town of Ampere, N. J., is often called out of its name in spite of the natural simplicity of the word. Ampere is named after the celebrated French scientist, whose name is also used throughout the world as the unit of electrical current. Letters addressed to Ampere (which, by the way, is the only place in existence so named) have borne the following words: Amfere, Amphion, Amperre, Ampore, Ampee, Amperr, Ampre, Ampire, Ampier, Ampiere, Ampsere, Ampero, Amperc, Ampen, Ambere, Amerer, Ampeal, Ampeare, Amphere, Amphen, Ampicre, Auspere, Ampeere, Ampers, Amperel, Ampeu, Monpere, Onyiere.

The town was named Ampere by the Crocker-Wheeler Company, manufacturer of electrical machinery. The name of the company has been variously written as follows: Corcker-Wheeler Company, Crocker-Wheller Company, Crooker-Wheeler Company, Crocker Water Motor Company, Croaker & Wheeler, Crocker-Wheeling Company, Crocker-Wheelwe Electric Company, Crocker-Wheel Company, Crocker-Wheeler Electric Company, Booker-Wheeler Company, Brocker-Wheeler Company, Crokett-Wheeler Company, Chrocker-Wheeler Company, Clocker-Wheeler, Cricker-Wheeler Company, Rocker-Wheeler Company, Croker & Wilson Gas Engine Company, Croker & Wheeler Company, Crosier Wheeler Electric Company, Crocker-Wheeles Company, Croker Willer Dynamo Company, Croper & Weeler Company, Croker-Wheeler Company, Croquer-Wheeler Company, Crocker-Whaler Motor Company, Crocker-Wheelef Company, Wicker & Wheeler, Vrocker Wheeler Company, Wheeler & Crocke, Crocker-Williams Company.

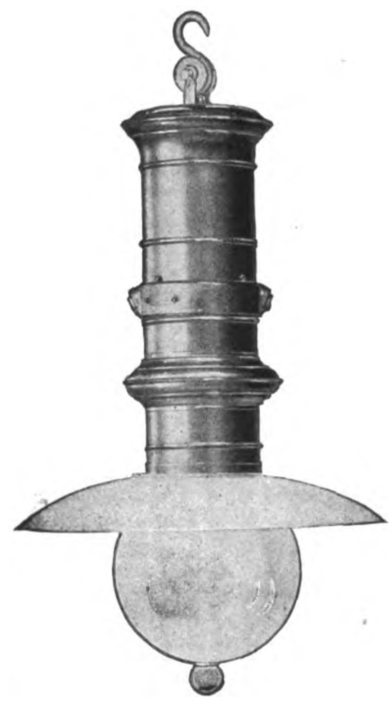
Electrical Supplies for the Navy Department.

The Bureau of Supplies and Accounts will open bids in Washington, D. C., on August 18 for the following electrical supplies: 35,000 arc-lamp carbons, 1,000 feet of lamp cord, miscellaneous fuses, miscellaneous electrical supplies, weatherproof wire and rubber-covered wire, for delivery at Norfolk, Va.; 2,500 feet of Circular Loom, miscellaneous electrical supplies, switches and rubber-covered wire, for delivery at Washington, D. C.: two feeder panels for delivery at Boston, Mass.

The "Stavelco" Semi-Enclosed Arc Lamp.

The accompanying illustration shows the new "Stavelco" semi-enclosed arc lamp which has been placed on the market by the Stave Electrical Company, No. 1 Madison avenue, New York city. It is claimed that by allowing a certain amount of the oxygen from the air to burn with the arc, the luminosity of the lamp is added to, and the ultra-violet rays are eliminated. The light emitted by this lamp is almost pure white, and is exceptionally favorable for department stores, printing plants and other industries where colors have to be matched under artificial illumination.

The mechanism of the lamp is decidedly simple and depends upon the clutch-feed



THE "STAVELCO" SEMI-ENCLOSED ARC LAMP.

principle. The matter of trimming the lamp has been carefully worked out, and the carbon guide is split at the lower end so that the carbon-holder is easily accessible for inspection. The life of the electrodes is between twenty-eight and thirty hours, and small-sized carbons are used. The diameter of the carbon is six millimetres, and the crater is thus confined to a small point on the carbon, and there is little tendency for the crater to travel on the outer edge of the carbon, resulting in a greater steadiness of light.

The efficiency of the lamp is stated to be very high. With a current consumption of four amperes, the mean hemispherical candle-power is 800.

The lamps are arranged so that they can burn in multiple on 110 volts or in series on 220 volts. They are made for either direct current or alternating current, and in the latter case for any frequency from forty cycles to 125 cycles.

Wagner Transformers for United States Reclamation Service.

An initial shipment of water-cooled power transformers, forming part of an ultimate equipment of thirty-six transformers, aggregating 10,530 kilowatts, for the United States Reclamation Service in connection with the Salt River, Arizona, irrigation project, has recently been made by the Wagner Electric Manufacturing Company. The specifications for these transformers were issued last July, and the contract was awarded to the Wagner company under severe requirements as to insulation, operating characteristics, etc., and also under rigid stipulations as to prompt delivery. The recent shipment comprises six 350-kilowatt, twenty-five-cycle, 2,300-26,000-volt step-up transformers and nine 235-kilowatt, twenty-five-cycle, 23,100-1,100-volt step-down transformers. The design of the transformers required dealing with certain special conditions at the places of installation, among which were the limited space for handling the transformers in the power-house, and the high temperature of the cooling water due to the hot climate of the desert region. The water is circulated through the cooling coil of each transformer by a Wagner three-phase motor-driven triplex pump.

New Shelby Tube Company Elects Officers.

Permanent organization of the new Shelby Tube Company has been perfected by the election of the following officers and directors:

President, J. C. Fish; vice-president, C. M. Skiles; second vice-president, C. S. Hook; general manager, A. C. Morse; secretary, Howard Seltzer; treasurer, James Brubaker. Directors: J. C. Fish, Charles Hook, G. M. Skiles, A. C. Morse, J. A. Seltzer, Roger Heath, Edwin Mansfield, H. W. Hilderbrandt, T. J. Green, Jonas Feigher, Y. O. Peters, Robert Greer, J. W. Williams, R. P. Bricker and C. S. Moore. The total amount of capital subscribed is $250,000. The company is incorporated for $500,000.

Ground will be broken soon at Shelby, Ohio, to erect the new tube mill. The United States Steel Corporation owned a tube mill at that place, and it was destroyed by fire about six weeks ago.

Current Electricai News

DOMESTIC AND EXPORT.

TO BUILD BIG POWER-HOUSE AT GRAND RAPIDS—At a directors' meeting of the Menominee & Marinette Light and Traction Company it was decided to increase the capital of the company from $450,000 to $1,000,000 for the purpose of building a power-house at Grand Rapids, Mich. Seven thousand horse-power will be developed by this plant, which will be brought to the cities of Menominee and Marinette. The necessary capital has been subscribed.

THE VANDERBILT ELECTRIC LINES—The Mohawk Valley Company, which has been the holding company for the Vanderbilt electric lines in New York, has certified to the secretary of state that it has reduced its capital stock from $20,000,000 to $7,500,000. The paper is signed by W. C. Brown as vice-president of the New York Central & Hudson River Railroad Company, and Horace E. Andrews as manager of the Central Railway syndicate. It is stated that the ascertainable debts and liabilities of the company are $7,104,-657, and that the amount of the reduction of the capital stock is to be distributed among the stockholders of the company. The capital stock of the Rochester & Eastern Railway Company, another Vanderbilt road, is increased from $1,500,000 to $15,290,200, the certificate being signed by Horace E. Andrews as president of the Mohawk Valley Company.

NEW COLORADO POWER PLANTS—Plans for th projected $1,000,000 improvements of the Empire Water and Power Company in Cascade Cañon, west of Colorado Springs, have been approved at a deferred annual stockholders' meeting, and work will be begun soon. The stockholders have authorized the issuance of a $1,000,000 mortgage and the delivery of $500,000 of its first mortgage bonds to a New York banking house, making this amount available at once. Three power plants will be built, one at Green Mountain Falls, a second at Cascade and a third at Manitou. The company will generate electricity by water received from its reservoirs on the north slope of Pike's Peak. The directors would not await the outcome of a suit by L. A. Bigger, of Kansas, owning property in the cañon, who seeks an injunction restraining the company from carrying out its plans on the ground that it will depreciate the beauty of the cañon.

NEW NORTH CAROLINA POWER COMPANY FORMED—The Charlotte Power Company has been formed under the laws of the state of New Jersey. Among those interested are W. S. Lee, W. H. Martin, L. C. Harrison and R. B. Arrington, all officials of the Southern Power Company, and in addition to these, it is understood that a number of prominent capitalists from New York are also behind the movement. The Southern Power Company, as a corporation, has a block of stock in it. The capital stock of the company is $300,000 and the charter provides for the construction and operation of gas, electric and lighting systems in and around Charlotte. The main offices of the concern will be located at Charlotte, from which point as a pivot operations will begin. Permanent organization is expected to be formed at an early date with the election of officers and the transaction of other business incidental to launching a project of such proportions.

NEW VIRGINIA ENTERPRISE—One of the biggest concerns organized in Virginia for a long time is that for which application has been made for a charter. It is the Roanoke Traction Company, with a capital stock of from $500,000 to $2,000,000. Roanoke, Lynchburg and Clifton Forge are to be the principal offices of the company, which is to engage in general lighting, heating and furnishing of power for all sorts of enterprises in the cities named. The power for developing this electricity is to be obtained from the James River, at what is known as the "Horseshoe," up above the city of Lynchburg. The water power there is susceptible of easy development and can be cheaply transmitted to the three cities named. At the same time the small towns intervening between the three cities will be able to have electric lights at the minimum of cost. James P. Wood, of Roanoke, is president; R. C. Jackson, vice-president; James C. Martin, secretary-treasurer. A check for $1,000 accompanied the application for the charter.

NEW PUBLICATIONS.

SOME THINGS A MANUFACTURER SHOULD KNOW ABOUT COAL—The Arthur D. Little Laboratory has issued as professional paper No. 3, an article entitled "Some Things a Manufacturer Should Know About Coal," by E. G. Bailey, chief of the coal department. The work of this laboratory is primarily directed toward increasing the efficiency of industrial effort, by aiding manufacturers, public service corporations and individual clients in the economical selection of raw materials, the mechanical control of processes and products, and the study of special problems. This article was originally presented as a paper at the annual meeting of the National Association of Cotton Manufacturers, held at Boston, Mass., April 16 and 17.

LIST OF APPROVED ELECTRICAL SUPPLIES—The Electrocraft Publishing Company, Detroit, Mich., announces that the third edition of the "Electrocraft Illustrated List of Approved Electrical Supplies" will shortly be issued, and that copies will be sent free of charge only to actual buyers of electrical supplies and persons directly influencing buying. The publisher requests immediate applications for copies, to be made on the letter-heads of the applicants and accompanied by ten cents in stamps or silver to pay postage. The new list will be greatly enlarged and improved, and everything electrical which has been approved by the Underwriters' Laboratories will be fully illustrated and described. It will also contain the National Electrical Code, illustrated and explained.

NEW INCORPORATIONS.

LOS ANGELES, CAL.—Needles Light and Power Company. $50,-000. Directors: W. B. Palmer, W. W. Perry and M. P. Thyl.

MILLTOWN, WIS.—Milltown Mutual Telephone Company, Milltown. $4,000. Incorporators: John H. Rahr, Mads Bank, Simon R. Tweeten.

LITTLE ROCK, ARK.—The Grant and Dallas County Telephone Company. $25,000. Incorporators: R. E. Harrison, president; M. G. Bell, secretary and treasurer.

BEALLSVILLE, OHIO—The Mellott Ridge Telephone Company, Beallsville. A. N. Varner, C. F. McDougal, L. A. Mellott, Charles Bolon, G. Pittman. Capital $30,000.

GUTHRIE, OKLA.—The Hackleberry Farmers' Telephone Company, McPeek. $5,000. Directors: D. M. Davis, D. E. Glency and J. C. Pierce, of Arnette; S. S. Lawrence, of Reason, and H. M. Connor, of McPeek.

DEPEW, OKLA.—Depew Telephone Company, Depew. $1,000. Directors: M. Pate, John S. Crail, L. N. Cothern, W. F. Malley, W. S. Langfitt, W. J. Green, E. W. Sims, J. M. Bryden, O. S. Coppage and W. A. Stanfield, all of Depew.

EASTON, ME.—Easton Electric Company. For the purpose of making, generating, distributing and supplying electricity in the town of Easton, Aroostook County, Maine. $5,000. Officers: President, C. N. Delaite, Easton; treasurer, C. W. Spear, Easton.

MILWAUKEE, WIS.—The Wayside Telephone Company, Wayside, Brown County; $2,000; incorporators: Joseph Hoffman, Thomas Monahan and John Natzke. The McKinley Telephone Company, McKinley, Polk County; $1,500; incorporators: E. J. Pfluger, Anton Lundmark and Oscar Risberg.

TELEPHONE AND TELEGRAPH.

PENNINGTON, N. J.—A special meeting of the Hopewell Township Committee was held on July 22 to vote on the proposition to grant Pennington Telephone Company, No. 1, the right to set poles along the public highway from T. Romine Voorhees's to Nathaniel F. Woodwards's. The committee decided unanimously in the telephone company's favor.

HILLSDALE, IND.—Residents of Hillsdale and vicinity have organized for the purpose of building an independent telephone line. At a meeting of a number of persons interested in this movement the following officers were elected to carry out the temporary organization: President, D. B. Highfill; secretary, John Fagler; treasurer, Samuel Hamersley.

CHIHUAHUA, MEXICO—Chihuahua has 553 telephones in its telephone system, an increase of fifty per cent in two years and a half. There are ten miles here in the city with 500 miles of wire and cable strung over them. The rural lines connected with the city office cover eighty-five miles. The system belongs to a local company which has invested $60,000. F. Lee Clevenger is manager.

SAN DIEGO, CAL.—Announcement is made that the Home Telephone Company of San Diego has been sold to an eastern syndicate. It is said that the purchasers paid $120,000 cash for the plant. The deal was conducted through Louis J. Wilde, president of the American National Bank of this city. An important extension to the system projected is the construction of a line to all points in the Imperial Valley.

MOUNT PULASKI, ILL.—According to a certificate filed with the circuit clerk, the Mount Pulaski Independent Telephone Company is no more. The certificate recites that at a meeting held in the Scroggin opera house, July 10, 220 votes out of 265 were represented and of this number 218 voted for a voluntary dissolution and two against it. In accordance with the vote, the company was dissolved, the property disposed of, debt paid and the residue paid those to whom it was due.

MEMPHIS, TENN.—A new long-distance telephone line between Memphis and Jackson, Miss., along the line of the Yazoo & Mississippi Valley Railroad, upon which construction work was stopped by the Cumberland Telegraph and Telephone Company last year, is to be rushed to completion. The line had been completed as far south as Belzoni, Miss., when suspension was ordered on account of hostile litigation instituted against the company and the heavy advance in the cost of construction material.

WHEELING, PA.—The control of the National Telephone Company of Wheeling, one of the largest of the independent companies of the section, has been secured by S. W. Harper and Hon. John A. Howard, of Wheeling, each taking about a third of the stock. The company has been reorganized, Mr. Howard being elected president; Mr. Harper vice-president and treasurer. The company will extend its operations in Washington County, Pa., where it has many franchises, doing much work in Washington borough at this time.

MORELIA, MEXICO—Several business men of Morelia have gotten together to form a stock company to construct a modern underground telephone installation. The company will be called "Compañia de Telefonos Comerciales." A contract has already been entered into with the firm of Siemens & Halske and the corresponding public deed has been drawn up before Notary Public Lic. Francisco Barroso. The stockholders have already made payment of the first assessment according to the by-law of the company, which is capitalized at $80,000.

PEORIA, ILL.—At a recent meeting of the directors of the Farmers' Mutual Telephone Company it was decided to open an office in Tremont, where headquarters will be established. The $20,000 stock of the company has all been subscribed and will be issued at once. The matter of building a new line or buying out an opposition company has been left to a committee and it will get down to business immediately. The proposed line will traverse six of the best townships in the county and has among its stockholders the best farmers of the county.

NASHVILLE, TENN.—The United States Trust Company, of Louisville, Ky., has filed a bill in the Federal Court asking for a receivership for the Home Telephone Company, of Clarksville, Tenn., and Ernest B. Denizen, who has been manager of the company at Clarksville, has been named receiver. The receivership is, in effect, a step in the direction of complete reorganization of the company. The bondholders are seeking to foreclose a mortgage for $140,000 spent in constructing the plant. The company controls exchanges in Montgomery, Houston and Stewart counties.

LAPORTE, IND.—The Merchants' Mutual Telephone Company, of Michigan City, and the Central Union Telephone Company, which for some time past have had under consideration the proposition of a consolidation of the telephone business in Michigan City, make public the fact that the negotiations are about completed and that the Mutual company is soon to absorb the Central Union's exchange and business. The Central Union plant is to be taken over by the Mutual company, the exchanges are to be consolidated and Michigan City will have but one exchange, operated by the Mutual company.

ST. LOUIS, MO.—The Bell Telephone Company of Missouri will erect an addition to its present building at the southeast corner of Beaumont and Locust streets, to cost about $75,000. The addition will have a frontage of fifty-three feet on Locust street, giving the entire structure a frontage of 100 feet on both Locust and Beaumont. The structure will conform in architecture with the present building. It will be of brick and stone and in all details modern. The improvement is planned to meet the growing business of the Beaumont exchange and long-distance station, located in the present building.

ALBUQUERQUE, N. M.—Colonel D. K. B. Sellers, representing important telephone interests, has let a contract to the Nash Electrical Supply Company, of this city, for the immediate construction of forty miles of telephone line from this city to Moriarty, in the Estancia Valley. The contract marks the beginning of a new telephone enterprise which is of first importance to Albuquerque, for not only will it give direct connection with all the towns in the Estancia Valley, but through additional lines now under construction will shortly give direct telephone connections with all the towns along the El Paso & Southwestern Railroad.

ELECTRIC LIGHTING.

BRUNSWICK, ME.—It is understood that the Brunswick Lighting and Power Company is negotiating for the purchase of the real estate and water rights of the Androscoggin Pulp Company.

BRAINERD, MINN.—A $120,000 bond issue has been voted by the city of Brainerd, Minn., for the construction of a new electric light plant and waterworks. The municipal plant does the exclusive electric lighting of Brainerd.

MORRISTOWN, N. J.—It is announced that negotiations have been concluded between the Public Service Corporation and the Morris & Somerset Electric Company whereby the latter leases for a term of 900 years the Public Service Corporation's Morristown electric lighting plant, which also includes franchises in Morris Township.

SILVER CITY, N. M.—The electric light company has been doing some extensive improvement work on its plant. New machinery sufficient to double the capacity of the plant has been installed and work on a new power-house is now in operation. Arrangements have been made to furnish motive power in any quantity to all consumers.

KINGSTON, N. Y.—The Public Service Commission, Second District, has granted the petition of the Kingston Gas and Electric Company for authority to issue $33,000 bonds, not to be sold for less than ninety, the proceeds to be devoted by the Kingston Gas and Electric Company for the refunding of the $32,500 bonds of the Rondout & Kingston Gas Light Company, which are past due.

POCATELLO, IDAHO—James H. Brady, president of the Idaho Consolidated Power Company, of Pocatello, and principal owner of various irrigation and power properties in this section of the state, including the Rexburg Light and Power Company, has closed a deal for the sale of the last-named property to T. M. Hodgins, of Butte, the consideration being $25,000. Mr. Hodgins is owner of the St. Anthony electric light and power plants, and will inaugurate a day and night service.

LEON, IOWA—The Leon Electric Light, Heat and Power Company is to be incorporated, the incorporation papers having already been filed. The company is to be incorporated with a capital stock of $15,000 and shares at $100 each will be offered for sale. The present owners, who are experienced electric light men, are preparing to use the funds derived from the sale of stock in the reorganized company for the improvement of the plant. H. E. Chase and W. S. Curtis are the owners of the plant.

HARTFORD, WIS.—The city council has purchased the L. Kissel & Sons' electric light plant, exclusive of power plant, the price paid being $5,000. The city voted some weeks ago to install a municipal alternating lighting plant at a cost of $27,000, bonds to be issued for that sum. The Kissel company has been operating an electric plant for a number of years, its franchise expiring this year. As it is not incorporated it was unable to secure an indeterminate franchise. The city will proceed at once to install a power plant on a site recently purchased.

YOUNGSTOWN, OHIO—The Consolidated Gas and Electric Company has secured a new contract for city lighting. The company agrees to light the city all night and every night from now until the end of the year at the present rate. The city is now paying $64 per year for each light on a moonlight schedule. The ordinance provides for an all-night and every-night schedule at $68 per light. As the semiannual appropriation has been made the company will have to furnish the light at the present rate, but has agreed to give an all-night and every-night schedule. The contract is for a term of five years.

FARMINGTON, ME.—Work will be begun shortly on the building of a 200-foot log dam with concrete bottom at Cleveland Rips, in North Anson, on the Carrabasset River, by the Franklin Power Company, chartered in 1903 under the name of the Carratunk Power Company, capitalized at $100,000, to provide Farmington, New Vineyard and ultimately the town of Wilton with electricity for illuminating and manufacturing purposes. The president of the Franklin Power Company is S. O. Tarbox, a well-known Farmington man, and the treasurer is C. O. Sturtevant, of Winthrop. Judge A. L. Fenderson, of Farmington, and Hon. George G. Weeks, of Fairfield, are on the board of directors.

CHEYENNE, WYO.—The Cheyenne Light, Fuel and Power Company has secured a new franchise of the city council, material concessions in rates having been made by the company. The new rate to consumers will be twelve cents per kilowatt-hour. The old rate was twenty cents and was reduced to fifteen cents, the company offering to make a further reduction to fourteen cents. Electricity for power will be five cents per horse-power-hour, all bills being subject to a discount for prompt payment, the minimum bill to be one dollar. The city has also secured a concession in the rate it is paying for street lights. The new franchise includes a contract for ten years; for five years the city is to pay $95 for its street lights each per year and for the remaining five years $90, when a new contract will be made. In order that the company may suffer no reduction of revenue by the reduction in rate, the city agrees to install additional lights to make the monthly payments the same as at present.

SALT LAKE CITY, UTAH—Work on the preliminary surveys for a third power plant for the Utah County Light and Power Company has begun. Professor Richard R. Lyman, of the University of Utah, is in charge of the work. The third power plant, which will be constructed by the company, will be built in Alpine Cañon, about six or eight miles from American Fork. The other two plants of the Utah County Light and Power Company are located in American Fork Cañon. Construction work on the second plant has hardly been completed, but the demand for electrical power has been so great within the last few years that the backers of this company deem it wise to build a third plant. Two sites have been suggested in Alpine Cañon for the third plant, but the matter of selecting the site will be held pending a report from Professor Lyman. The Utah County Light and Power Company furnishes the electrical power for the pumping plant owned by Salt Lake City at the mouth of the Jordan River. Last spring the company secured a contract to supply the Knight smelter at Tintic with electrical power. The power line has only recently been completed. Electrical energy will soon be transmitted to and used at the smelter at Silver City. Besides having these two large contracts, the company supplies all the electric light used in the northern end of Utah County.

ELECTRICAL SECURITIES.

While prices still made slight gains last week, there was apparent a falling off in speculative activity and a diminution in the interest manifested by the outside public in both stocks and bonds. The commission houses reported considerably curtailed business, and it is expected that the present month will witness some slight reaction, although business is expected to continue improving. While it is agreed quite generally that there will be very little improvement in the value of stocks until after the election in the fall, it must be remembered that prices are now at a higher level than they were last August. This is particularly significant of the fact that the present prices will discount considerably gains for the next three or four months. The report of the United States Steel Corporation for the second or June quarter was considered reasonably assuring. Net earnings were slightly larger, but orders on hand showed a small decrease. The improvement in profits reflects the gradual recovery of this important industry.

Dividends have been declared upon the following electrical securities: Electric Properties Company, regular quarterly dividend of 1½ per cent on the preferred stock, payable August 10; Consolidated Gas Company, regular quarterly dividend of 1 per cent, payable September 15 to stock of record August 19. Susquehanna Railway, Light and Power Company, regular semi-annual dividend of 2½ per cent on the preferred stock, payable September 1 to stock of record August 15.

ELECTRICAL SECURITIES FOR THE WEEK ENDED AUGUST 1.

LEGAL NOTE.

METAL SLEEVE DRUM CONTROLLER CASE—Judge Taylor has handed down an opinion in the United States Circuit Court, Northern District of Ohio, Eastern Division, June 24, in the Metal Sleeve Drum Controller case, involving the Lange and Lamme patent No. 518,693, between Westinghouse Electric and Manufacturing Company, complainant, and the Electric Controller and Supply Company, defendant, adjudging the validity of the patent, and concluding that infringement has been discovered.

PERSONAL MENTION.

MR. C. E. F. AHLM has been retained as consulting engineer by the Board of Public Service of Wooster, Ohio, in connection with the proposed municipal electric lighting plant for that city.

MR. CYRUS OSBORNE BAKER, the head of the house of Baker & Company, and known as the platinum king of America, is spending the month of August at the Samoset, Rockland Breakwater, Me.

MR. ARTHUR H. KIMBALL has resigned as superintendent of the Fitchburg Gas and Electric Light Company to accept the position of general manager of the Fall River Electric Lighting Company.

MR. E. J. KULAS, one of the well-known men in the incandescent lamp field, and for years secretary and general manager of the Brilliant Electric Company, of Cleveland, Ohio, has been elected president and general manager of the Tungstolier Company, of Cleveland. The "Tungstolier" is a new departure in electric lighting, consisting of tungsten lamps, Holophane shades, and a special fixture, the whole presenting a practical and harmonious illuminating device which may be utilized for every character of electrical illumination. Mr. Kulas has been very successful in his management of the Brilliant Electric Company, and the same forceful, enterprising and affable characteristics will win for the Tungstolier Company the hearty support of all those requiring lighting devices of this nature.

ELECTRIC RAILWAYS.

MADISON, WIS.—Solomon Perris, attorney for the Interstate Transfer Railroad Company, appeared recently before the railroad commission to ask for a certificate to authorize the road to begin at once the construction of a line from the steel mills near Duluth to Superior.

HAGERSTOWN, MD.—A movement is on foot to construct a trolley line from Hagerstown to Security, a village located about two miles east of Hagerstown. A cement plant costing over $1,000,000 is being erected at Security by the Maryland Portland Cement Company, in which Baltimoreans are interested.

FREMONT, OHIO—The Fremont City Railway, now operating a line between Fremont and Ballville, a village on the south, has made application to the city council for a franchise which will enable the company to extend its lines to the Lake Shore station and to Spiegel Grove, the Hayes home. The council now has the application under advisement.

GRAND JUNCTION, COL.—The city council has granted a twenty-year franchise to the Fruit Belt Power Company for the construction of a street-car line in the city of Grand Junction and from Grand Junction to Fruita. The company is controlled by Colorado Springs and Grand Junction capital. The work on the new road is to begin under the terms of the grant by October 1.

BETHLEHEM, PA.—A new trolley company has been organized at Mauch Chunk and named the Carbon Transit Company. These are the officers and directors: president, Horace Lentz; vice-president, J. C. Dolan; secretary and treasurer, Charles Neast; directors, John C. Dolan, N. D. Cortright, Horace Lentz, Charles Neast, of Mauch Chunk; George K. Moser and Andrew S. Keck, of Allentown.

PENDLETON, ORE.—The city council has granted eastern capitalists a franchise for a street railway system through Pendleton. Work will begin soon. Connection will eventually be made with Columbia River and different Umatilla County points. Montie B. Gwinn represented the company before the council. The capitalists back of the project are the same Pittsburg people who built the line from Bois to Caldwell, Idaho.

UNIONTOWN, PA.—Plans have been made to build an interurban traction line across the Allegheny Mountains from Oakland, Md., to Uniontown, Pa., most of the way near the main line of the Baltimore & Ohio. The company will be known as the Oakland, Sparrow Falls & Uniontown Electric Railway. A charter has been secured in Maryland and one will be secured in Pennsylvania by J. B. Hogg and others, of Uniontown. A double-track survey from Swallow Falls to Oakland is now being made.

MONROE, MICH.—The city council has granted a street-railway franchise to the Toledo, Ottawa Beach & Northern. Provision is made that the company shall forfeit $2,000 for each year the road is not completed and in operation after three years from the date of the franchise. It is the purpose of the company to extend the road to Detroit as soon as possible. Right-of-way agents have been busy for some time, and it is anticipated that everything will be in readiness to proceed with construction next spring.

DENVER, COL.—Articles of incorporation have been filed with the secretary of state by the Burlington Interurban Railway Company for the board of directors. The incorporators are: Ray C. Watson, Frederick O. Olsan, John P. Klug, Frank K. Hatch, Charles I. Moore, Clarence A. Fletcher and Milton L. Chapman. The company is capitalized at $2,500,000 and has its principal offices in Denver. It will operate electric cars in the counties of Denver, Adams, Larimer and Weld and will have terminals at Denver, Fort Collins and Crow Creek in Weld County. The existence of the corporation is fifty years.

LAKE CHARLES, LA.—The Lake Charles Railway and Light Company will take over the franchises and property of the Lake Charles Street Railway Company. The capital stock of the company is fixed at $750,000, divided into shares of $100 each. One-third, or $250,000, shall be preferred stock, bearing a fixed dividend of six per cent, and the rest common stock that shares in the ordinary net profit. The officers and first board of directors follow: Thompson J. Bird, president; J. Alfred Landry, first vice-president; D. J. Landry, second vice-president; A. J. Pujo, third vice-president; Paul O. Moss, treasurer.

JANESVILLE, WIS.—With the incorporation of the Cincinnati Construction Company, which seeks to build an electric interurban railroad between Janesville and Madison, the first step in the construction of the road proposed by an Ohio syndicate was made The incorporators are all Janesville men, being J. M. Bostwick, M. P. Richardson, Archie Reid, P. H. Korst and Richard Valentine. Chief Engineer Joseph Ellis, of Columbus, has finished the first survey of the line from Janesville to Stoughton. It is understood the road will run from Janesville to Madison by way of Edgerton and Stoughton. It will leave Janesville by what is known as the river road and cross the Rock River above Indian Ford. It will be an air line, running to the west of both lakes Kegonsa and Waubesa.

ALLENTOWN, PA.—Mayor Stiles signed the ordinance providing for trolley freight in Allentown. It was passed by councils on July 14, granting the privilege to the Lehigh Valley Transit Company to establish a trolley express service, under certain reasonable restrictions. The cars are to be neat and no freight is to be carried which would be dangerous or offensive. The establishing of a trolley freight system was conceived by President Stevens. The freight house in Allentown is to be located at the old power-house. A special effort will be made to establish a prompt and efficient service to Philadelphia, as well as all other points along the system. From present indications the Philadelphia Milk Exchange will ask the Transit Company to put on refrigerator cars to carry milk. It is proposed to expend $80,000 to start the service.

COLUMBUS, OHIO—At a meeting of the board of directors of the Scioto Valley Traction Company, held recently, the franchise lately granted the company by the city council of Chillicothe was accepted. The company has been making a fight for this franchise ever since the line was completed to Chillicothe some three years ago. The city insisted that the Scioto Valley must enter over the track of the local street railway company, which would have added largely to the mileage operated by the interurban cars. The traction company refused to do this, and as a result has stopped at the corporation line. In the end, however, the company gets the right to lay its own tracks in Chillicothe, and thus will gain an entrance into the heart of the city by the construction of about 2,000 feet of new line. The franchise will mean much more traffic for the company to and from Chillicothe.

INDUSTRIAL ITEMS.

THE NOVELTY INCANDESCENT LAMP COMPANY, Emporium, Pa., is distributing its usual attractive monthly calendar card.

FOX BROTHERS & COMPANY, 126-130 Lafayette street, New York city, are mailing a card calling attention to the merits of the "Polar" flaming arc lamp and the "Radiante" Economy lamps.

THE F. BISSELL COMPANY, Toledo, Ohio, has ready for distribution its calendar card for August. This contains the suggestion that "it is easy to see through" the constant increase in the company's business. The allusion is completed by reference to a piece of clear window glass.

THE DIEHL MANUFACTURING COMPANY, Elizabethport, N. J., is distributing several attractive bulletins, as follows: No. 20, direct-current ceiling fans; No. 21, direct-current Universal fans; No. 151, types "F" and "FC" motors and generators; No. 501, small ventilating fans; No. 502, electric coffee mill.

THE GAS MACHINERY COMPANY, 715-722 Citizen Building, Cleveland, Ohio, announces that the Wile producer heretofore furnished by the Wile Power Gas Company will hereafter be exclusively manufactured by the Gas Machinery Company. J. I. Wile will be sales manager of the Wile producer department.

THE FORT WAYNE ELECTRIC WORKS, Fort Wayne, Ind., has issued bulletin No. 1,107, describing and illustrating standard alternating-current, single-phase switchboard panels. Bulletin No. 1,108 describes and illustrates multiphase, revolving-field, belted generators, form A. Copies of these bulletins will be furnished to those interested upon request.

THE ALLIS-CHALMERS COMPANY, Milwaukee, Wis., has prepared a bulletin describing in detail an American Blower engine direct-connected to an Allis-Chalmers "NJ" generator. The conditions met with in small isolated light and power plants in public places, factories, private residences and aboard ship are satisfied in this combination of engine and generator. Copies of this bulletin, No. 1,042-A, will be furnished to those interested upon request.

THE AMERICAN DISTRICT STEAM COMPANY, Lockport, N. Y., on Friday, the 24th ult., suffered the loss by fire of a portion of its Tonawanda plant, where is located its casting mill and foundry. Plans are made for rebuilding the burned portion on an enlarged scale, which is to be of fireproof construction as nearly as may be. The company states that its business for the season will not be delayed on account of the fire. The loss is fully covered by insurance.

DOSSERT & COMPANY, 242 West Forty-first street, New York city, have received orders from Westinghouse, Church, Kerr & Company for 115 special solderless elbow-connectors, 300 and 600-ampere sizes, to connect the station buses through oil switches to the 2,400-volt outgoing lines at the Dutch Point station of the Hartford Light and Power Company, Hartford, Ct. These elbow-connectors can be used to make joints at either right or left angles, and afford a striking illustration of the flexibility of the Dossert devices.

THE MASSACHUSETTS CHEMICAL COMPANY, Boston, Mass., announces that it has entered into a contract with one of the great and conservative insulated-wire manufacturers to supply its entire requirements of cable cloth. The wire and cable company has for many years made its own cable cloth, but has been convinced that by delegating this part of its cable making to the Massachusetts Chemical Company it will get not only a better and more uniform product, but get it at a lower cost per yard than it has been producing it itself.

THE GENERAL ELECTRIC COMPANY, Schenectady, N. Y., has issued two bulletins, 4,601 and 4,602, describing its improved automatic voltage regulators. These are made in various styles for the regulation of one generator or of two or more generators in parallel, either alternating or direct current. Bulletin 4,609 describes a new lamp-testing watt indicator. This instrument is of the portable type and may be carried in the pocket, is intended for use with Edison base lamps, but can be fitted with an adapter for use with either Thomson-Houston or Westinghouse socket lamps, and is designed to give a practical demonstration of the relative watt consumption of various incandescent lamps.

THE CENTRAL ELECTRIC COMPANY, Chicago, Ill., is distributing information on its meter-testing load box for use in testing integrating wattmeters, either in the laboratory or at the point of installation. The boxes are of novel design in that the various resistance units are mounted in enclosed fuse clips and are handled in very much the same manner as the Standard Code fuses. The company is also distributing a new handbook giving considerable data on lighting with tungsten lamps. Tables are given showing the cost of lighting with tungsten lamps as compared with gas mantles and gas arcs, this being worked out at various values from two cents to thirteen cents per kilowatt-hour. This book embodies some twenty-four pages and should prove of interest to central stations in demonstrating to their customers the efficiency of tungsten lamps.

Directory of Electrical and Allied Engineering and Scientific Societies.

(Published in the Second Issue of Each Month.)

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE. Secretary, L. O. HOWARD, Cosmos Club, Washington, D. C.

AMERICAN ELECTROTHERAPEUTIC ASSOCIATION. Secretary, Dr. Albert C. Geyser, 352 Willis avenue, New York city.

AMERICAN ELECTROCHEMICAL SOCIETY. Secretary, Dr. J. W. Richards, Bethlehem, Pa. Fall meeting, New York city, October 30-31.

AMERICAN FOUNDRYMEN'S ASSOCIATION. Secretary, Dr. Richard Moldenke, Watchung, N. J.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS. Secretary, Ralph W. Pope, Engineering Societies Building, 29 West Thirty-ninth street, New York city.

AMERICAN MATHEMATICAL SOCIETY. Secretary, F. N. Cole, 50 West 116th street, New York city.

AMERICAN RAILWAY MASTER MECHANICS' ASSOCIATION. Secretary, J. W. Taylor, Old Colony Building, Chicago, Ill.

AMERICAN ROENTGEN RAY SOCIETY. Secretary, Dr. G. C. Johnson, 514 Bijou Building, Pittsburg, Pa.

AMERICAN SOCIETY FOR TESTING MATERIALS. Secretary, Professor Edgar Marburg, University of Pennsylvania, Philadelphia, Pa.

AMERICAN SOCIETY OF CIVIL ENGINEERS. Secretary, Charles Warren Hunt, 220 West Fifty-seventh street, New York city.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS. Secretary, Calvin W. Rice, 29 West Thirty-ninth street, New York city.

AMERICAN SOCIETY OF MUNICIPAL IMPROVEMENTS. Secretary, G. W. Tillson, Park Row Building, New York city. Annual meeting, Atlantic City, N. J., October.

AMERICAN STREET AND INTERURBAN RAILWAY ASSOCIATION. Secretary, B. V. Swenson, Engineering Societies Building, 29 West Thirty-ninth street, New York city. Annual convention, Atlantic City, N. J., October 12-16.

AMERICAN STREET AND INTERURBAN RAILWAY ACCOUNTANTS' ASSOCIATION. Secretary, Elmer M. White, treasurer Birmingham Railway, Light and Power Company, Birmingham, Ala. Annual convention, Atlantic City, N. J., October 12-16.

AMERICAN STREET AND INTERURBAN RAILWAY CLAIM AGENTS' ASSOCIATION. Secretary, B. B. Davis, claim agent Columbus Railway and Light Company, Columbus, Ohio. Annual convention, Atlantic City, N. J., October 12-16.

AMERICAN STREET AND INTERURBAN RAILWAY ENGINEERING ASSOCIATION. Secretary, J. W. Corning, electrical engineer Boston Elevated Railway Company, Boston, Mass. Annual convention, Atlantic City, N. J., October 12-16.

AMERICAN STREET AND INTERURBAN RAILWAY MANUFACTURERS' ASSOCIATION. Secretary, George B. Keegan, 2321 Park Row Building, New York city. Annual convention, Atlantic City, N. J., October 12-16.

ARKANSAS INDEPENDENT TELEPHONE ASSOCIATION. Secretary, Charles F. Speed, Texarkana, Ark.

ASSOCIATION OF EDISON ILLUMINATING COMPANIES. Secretary, W. W. Freeman, vice-president and general manager Edison Electric Illuminating Company, Brooklyn, N. Y.

ASSOCIATION OF ELECTRIC LIGHTING ENGINEERS OF NEW ENGLAND. Secretary, Welles E. Holmes, 308 Washington street, Newton, Mass.

ASSOCIATION OF RAILWAY TELEGRAPH SUPERINTENDENTS. Secretary, P. W. Drew, Wisconsin Central Railway, Milwaukee, Wis.

CALIFORNIA ELECTRIC RAILWAY ASSOCIATION. Secretary, L. E. W. Pioda, Oak and Broderick streets, San Francisco, Cal.

CALIFORNIA INDEPENDENT TELEPHONE ASSOCIATION. Secretary, P. T. Whittier, Spencer, Cal.

CANADIAN ELECTRICAL ASSOCIATION. Secretary, T. S. Young, Toronto, Canada.

CANADIAN STREET RAILWAY ASSOCIATION. Secretary, Acton Burrows, 33 Melinda street, Toronto, Ontario.

CENTRAL ELECTRIC RAILWAY ASSOCIATION. Secretary, W. F. Milholland, secretary and treasurer Indianapolis Traction and Terminal Company, Indianapolis, Ind.

COLORADO ELECTRIC LIGHT, POWER AND RAILWAY ASSOCIATION. Secretary, J. F. Dostal, Denver, Col. Annual convention, Glenwood Springs, Col., September 16-18.

CONNECTICUT STATE STREET RAILWAY ASSOCIATION. Secretary, F. W. Poole, Bridgeport, Ct.

ELECTRIC CLUB OF CLEVELAND. Secretary, George L. Crosby, 1200 Schofield Building, Cleveland, Ohio.

ELECTRICAL CONTRACTORS' ASSOCIATION OF NEW YORK STATE. Secretary, John P. Faure, 77 Water street, Ossining, N. Y.

ELECTRICAL CONTRACTORS' ASSOCIATION OF STATE OF MISSOURI. Secretary, Charles J. Sutter, 1220 Pine street, St. Louis, Mo.

ELECTRICAL TRADES ASSOCIATION OF CHICAGO. Secretary, Frederic P. Vose, Marquette Building, Chicago.

ELECTRICAL TRADES ASSOCIATION OF PHILADELPHIA. Secretary, E. A. Symmes, 810 Drexel Building, Philadelphia, Pa. Meetings, second and fourth Thursdays of each month.

ELECTRICAL TRADES ASSOCIATION OF CANADA, LIMITED. Secretary, William R. Stanley, Royal Insurance Building, Montreal, Canada.

ELECTRICAL TRADES ASSOCIATION OF THE PACIFIC COAST. Secretary, Albert H. Elliott, Claus Spreckels Building, San Francisco, Cal. Monthly meetings, San Francisco, first Thursday of each month.

ELECTRICAL TRADES SOCIETY OF NEW YORK (Member National Electrical Trades Association). Secretary, Franz Neilson, 80 Wall street, New York city. Board of directors meets second Friday of each month.

EMPIRE STATE GAS AND ELECTRIC ASSOCIATION. Secretary, Charles H. B. Chapin, 154 Nassau street, New York city.

ENGINEERS' CLUB OF PHILADELPHIA. Secretary, H. G. Perring, 1317 Spruce street, Philadelphia, Pa.

ENGINE BUILDERS' ASSOCIATION OF THE UNITED STATES. Secretary, J. I. Lyle, 39 Cortlandt street, New York city.

ILLINOIS INDEPENDENT TELEPHONE ASSOCIATION. Secretary, C. A. Camp, Henry, Ill.

ILLINOIS STATE ELECTRICAL ASSOCIATION. Secretary, H. E. Chubbuck, La Salle, Ill.

ILLUMINATING ENGINEERING SOCIETY. Secretary, Van Rensselaer Lansingh, Engineering Societies Building, 33 West Thirty-ninth street, New York city. Annual convention, Philadelphia, Pa., October 6-7.

INDEPENDENT TELEPHONE ASSOCIATION OF TEXAS AND LOUISIANA. Secretary, C. A. Shock, Sherman, Tex.

INDIANA ELECTRIC RAILWAY ASSOCIATION. Secretary, P. H. White, Indianapolis, Ind. Monthly meetings, second Tuesday of each month.

INDIANA INDEPENDENT TELEPHONE ASSOCIATION. Secretary, C. S. Norton, Indianapolis, Ind.

INTERNATIONAL ASSOCIATION OF MUNICIPAL ELECTRICIANS. Secretary, Frank P. Foster, Corning, N. Y. Annual meeting, Detroit, Mich., August 19-21.

INTERNATIONAL INDEPENDENT TELEPHONE ASSOCIATION. Secretary, J. B. Ward, Grand Rapids, Mich.; assistant secretary, J. A. Harney, Monadnock Building, Chicago, Ill.

IOWA ELECTRICAL ASSOCIATION. Secretary, W. N. Keiser, Des Moines, Iowa.

IOWA INDEPENDENT TELEPHONE ASSOCIATION. Secretary, C. C. Deering, Boone, Iowa.

IOWA STREET AND INTERURBAN RAILWAY ASSOCIATION. Secretary, L. D. Mathes, Dubuque, Iowa.

KANSAS GAS, WATER, ELECTRIC LIGHT AND STREET RAILWAY ASSOCIATION. Secretary, James D. Nicholson, Newton, Kan.

KENTUCKY INDEPENDENT TELEPHONE ASSOCIATION. Secretary, W. G. Turpine, Henderson, Ky.

MAINE INDEPENDENT TELEPHONE ASSOCIATION. Secretary, M. E. Crow, Houlton, Me.

MAINE STREET RAILWAY ASSOCIATION. Secretary, E. A. Newman, 471 Congress street, Portland, Me.

MASSACHUSETTS STREET RAILWAY ASSOCIATION. Secretary, Charles S. Clark, 70 Kilby street, Boston, Mass. Meets second Wednesday of each month, except July and August.

MASTER CAR BUILDERS' ASSOCIATION. Secretary, J. W. Taylor, 390 Old Colony Building, Chicago, Ill.

MICHIGAN ELECTRIC ASSOCIATION. Secretary, A. C. Marshal, Port Huron, Mich. Annual meeting, Grand Rapids, Mich., August 18-21.

MICHIGAN INDEPENDENT TELEPHONE ASSOCIATION. Secretary, A. A. Burch, Battle Creek, Mich.

MISSOURI ELECTRIC LIGHT, GAS AND STREET RAILWAY ASSOCIATION. Secretary, Claude L. Clary, Sikeston Electric Light and Power Company, Sikeston, Mo.

MISSOURI INDEPENDENT TELEPHONE ASSOCIATION. Secretary, George W. Schweer, Windsor, Mo.

NATIONAL ARM, PIN AND BRACKET ASSOCIATION. Secretary, J. B. Magers, Madison, Ind.

NATIONAL ELECTRICAL CONTRACTORS' ASSOCIATION OF THE UNITED STATES. Secretary, W. H. Morton, 94 Genesee street, Utica, N. Y.

NATIONAL ELECTRICAL TRADES ASSOCIATION. Secretary, Frederic P. Vose, 1343 Marquette Building, Chicago.

NATIONAL ELECTRIC LIGHT ASSOCIATION. Secretary, John F. Gilchrist, Commonwealth Edison Company, Chicago, Ill.

NEBRASKA ELECTRICAL ASSOCIATION. Secretary, William Bradford, Lincoln.

NEBRASKA INDEPENDENT TELEPHONE ASSOCIATION. Secretary, R. E. Mattison, Lincoln, Neb.

NEW ENGLAND ELECTRICAL TRADES ASSOCIATION. Secretary, Alton F. Tupper, 60 State street, Boston, Mass.

NEW ENGLAND STREET RAILWAY CLUB. Secretary, John J. Lane, 12 Pearl street, Boston, Mass. Meetings held on fourth Thursday of every month.

NEW YORK ELECTRICAL SOCIETY. Secretary, G. H. Guy, Engineering Societies Building, 29 West Thirty-ninth street, New York city.

NEW YORK STATE INDEPENDENT TELEPHONE ASSOCIATION. Secretary, R. Max Eaton, Niagara Falls, N. Y.

NORTHWESTERN ELECTRICAL ASSOCIATION. Secretary, R. N. Kimball, Kenosha, Wis.

OHIO ELECTRIC LIGHT ASSOCIATION. Secretary, D. L. Gaskill, Greenville, Ohio. Annual convention, Put-in-Bay, Ohio, August 25-27.

OHIO INDEPENDENT TELEPHONE ASSOCIATION. Secretary, O. O. Welsheimer, Columbus, Ohio.

OHIO SOCIETY OF MECHANICAL, ELECTRICAL AND STEAM ENGINEERS. Secretary, F. W. Ballard, Cleveland, Ohio.

OHIO STREET RAILWAY ASSOCIATION. Secretary, Charles Currie, Akron, Ohio.

OKLAHOMA ELECTRIC LIGHT, RAILWAY AND GAS ASSOCIATION. Secretary, Galen Crow, Guthrie, Okla.

OLD TIME TELEGRAPHERS' AND HISTORICAL ASSOCIATION. Secretary, John Brant, 195 Broadway, New York city.

ORDER OF THE REJUVENATED SONS OF JOVE. C. B. Roulet, Mercury, Dallas, Tex.

PACIFIC COAST ELECTRIC TRANSMISSION ASSOCIATION. Secretary, Samuel G. Reed, Portland, Ore.

PENNSYLVANIA STATE INDEPENDENT TELEPHONE ASSOCIATION. Secretary, H. E. Bradley, 135 South Second street, Philadelphia.

PENNSYLVANIA STATE STREET RAILWAY ASSOCIATION. Secretary, Charles H. Smith, Lebanon, Pa.

PIKE'S PEAK POLYTECHNIC SOCIETY. Secretary, E. A. Sawyer, Colorado Springs, Col. Meetings, second Saturday of each month.

RAILWAY SIGNAL ASSOCIATION. Secretary, C. C. Rosenberg, Bethlehem, Pa.

SOCIETY FOR THE PROMOTION OF ENGINEERING EDUCATION. Secretary, Arthur L. Williston, Pratt Institute, Brooklyn, N. Y.

SOUTH DAKOTA INDEPENDENT TELEPHONE ASSOCIATION. Secretary-Treasurer, E. R. Buck, Hudson, S. D.

SOUTHWESTERN ELECTRICAL AND GAS ASSOCIATION. Secretary, J. A. Myler.

STREET RAILWAY ASSOCIATION OF THE STATE OF NEW YORK. Secretary, J. H. Pardee, J. G. White & Company, New York, N. Y.

TEXAS INDEPENDENT TELEPHONE ASSOCIATION. Secretary, Charles F. Speed, Texarkana, Tex.

UNDERWRITERS' NATIONAL ELECTRIC ASSOCIATION. Secretary Electrical Committee, C. M. Goddard, 55 Kilby street, Boston, Mass.

VERMONT AND NEW HAMPSHIRE INDEPENDENT TELEPHONE ASSOCIATION. Secretary-treasurer, G. W. Buzzell, St. Johnsbury, Vt.

VERMONT ELECTRICAL ASSOCIATION. Secretary, C. C. Wells, Middlebury Electric Light Company, Middlebury, Vt.

VIRGINIA STATE INDEPENDENT TELEPHONE ASSOCIATION. Secretary, B. L. Fisher, Rocky Mount, Va.

WESTERN ASSOCIATION OF ELECTRICAL INSPECTORS. Secretary, W. S. Boyd, 382 Ohio street, Chicago, Ill.

WESTERN SOCIETY OF ENGINEERS (Electrical Section). Secretary, J. H. Warder, 1737 Monadnock Block, Chicago, Ill.

WISCONSIN ELECTRIC AND INTERURBAN RAILWAY ASSOCIATION. Secretary, Clement C. Smith, president Columbia Construction Company, Milwaukee, Wis.

WISCONSIN INDEPENDENT TELEPHONE ASSOCIATION. Secretary, J. C. Crowley, Jr., Superior, Wis.

DATES AHEAD.

Michigan Electric Association. Annual meeting, Grand Rapids, Mich., August 18-21.

International Association of Municipal Electricians. Annual convention, Detroit, Mich., August 19-21.

Ohio Electric Light Association. Annual convention, Put-in-Bay, Ohio, August 25-27.

Colorado Electric Light, Power and Railway Association, Glenwood Springs, Col., September 16-18.

Old Time Telegraphers' and Historical Association, and Reunion of Military Telegraphers, Niagara Falls, N. Y., September 16-18.

Illuminating Engineering Society. Annual convention, Philadelphia, Pa., October 6-7.

American Street and Interurban Railway Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Accountants' Association. Annual convention, Atlantic City, N. J., October 12-16.

American Electrochemical Society. Fall meeting, New York city, October 30-31.

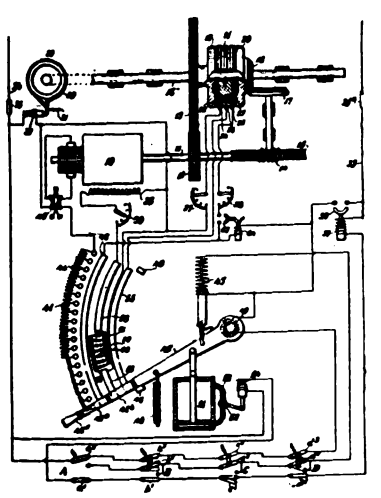
Record of Electrical Patents.

Week of July 28.

894,193. INCANDESCENT LAMP. William W. Dean, Chicago, Ill., assignor to Kellogg Switchboard and Supply Company, Chicago, Ill. A telephone signal lamp, the ends of the terminals being bent so as partially to enclose the bulb.

894,199. SYSTEM OF CONTROL FOR ELECTRIC MOTORS. Ralph M. Gaston, Morgan Park, Ill. A controller in an auxiliary circuit governs a motor which controls the operating current.

894,201. INSULATOR. Thomas E. Hallett, Chicago, Ill. The insulator is held on a rigid support by a threaded wedge.



894,232.—MOTOR-CONTROLLING SYSTEM.

894,212. TROLLEY GUARD. George S. Keck, Baltimore, Md. Laterally swinging guard arms are provided.

894,214. TELEGRAPHY. Isidor Kitsee, Philadelphia, Pa. A system employing true current reversals and using an inductorium for this purpose.

894,217. ELECTRIC RAILWAY. Mathias A. Lazareff, New York, N. Y. A sectional supply conductor normally connected to the feeder is used, the connecting switches being held open by electromagnets.

894,232. MOTOR-CONTROLLING SYSTEM. Walter J. Richards, Norwood, Ohio, assignor to Allis-Chalmers Company. Gears for driving at different speeds are controlled by magnetic clutches.

894,233. SYSTEM OF MOTOR CONTROL. Walter J. Richards, Norwood, Ohio, assignor to Allis-Chalmers Company. A controller operated from a distance.

894,237. MEANS FOR CHARGING STORAGE BATTERIES. Mary N. Stivers, Jersey City, N. J. A reversing motor is connected in an auxiliary circuit, the former being mechanically connected to the controlling rheostat.

894,257. TELEPHONE APPARATUS. Arthur M. Cobb, Lynn, Mass. A telephone head set supporting two receivers and one transmitter.

894,258. TELEPHONE APPARATUS. Arthur M. Cobb, Lynn, Mass. A head set with a universal joint for the transmitter.

894,305. TURBO-GENERATOR. Alfred H. Wouters, Norwood, Ohio, assignor to Allis-Chalmers Company and the Bullock Electric Manufacturing Company. An enclosing end bell is provided for supporting the end turns.

894,317. ELECTRODE FOR ELECTROLYTIC OR LIQUID OSCILLATION-DETECTORS FOR WIRELESS TELEGRAPHY. Lee de Forest, New York, N. Y. An electrode of the insulation-covered type for detecting feeble electrical impulses.

894,318. AEROPHORE. Lee de Forest, New York, N. Y., assignor, by mesne arrangements, to De Forest Radio Telephone Company. A device for transmitting electromagnetic waves in predetermined directions.

894,323. ELECTRIC WATER-HEATER. Frank E. Holt, Vancouver, British Columbia, Canada. The water passes through a series of passages, each of which is provided with a heating element.

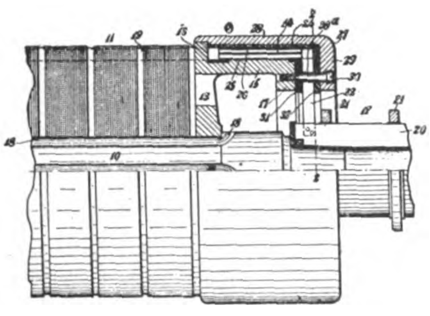
894,326. ELECTRIC SWITCH-REGISTER. John H. Jackson, Watonga, Okla. The track switch automatically closes an electric signal in circuit.

894,329. ELECTRIC GENERATOR OR MOTOR. Carlton L. Kennedy, Braintree, Mass. The pole-pieces are divided and provided with magnetic shunts.

894,333. ELECTRICALLY PROPELLED VEHICLE. Joseph Ledwinka, Philadelphia, Pa., assignor to Russell Thayer, Philadelphia, Pa. A car drawing its power intermittently from an external wire or a storage battery.

894,378. WIRELESS SIGNALING APPARATUS. Lee de Forest, New York, N. Y., assignor to De Forest Radio Telephone Company. The combination of a sending device having a plurality of wave producers and a receiving apparatus consisting of a plurality of complemental wave-responsive devices.

894,435. ELECTROLYTIC APPARATUS FOR PURIFYING LIQUIDS. John T. Harris, New York, N. Y. Water is passed between parallel electrodes formed of metal capable of yielding a colloidal hydroxide.



894,305.—Turbo-Generator.

894,460. TELEPHONE TRANSMITTER. Emile J. Pitrat, Urbana, Ill. A receiver in which the button is kept vertical although the diaphragm may be set at different angles.

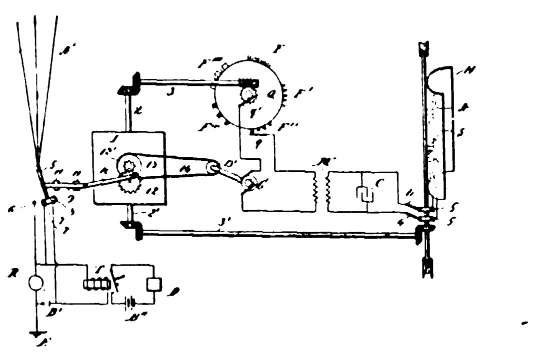
894,468. TANK INDICATOR. Julius E. Smith, North Lansing, Mich. A float for closing a signal circuit when the tank is filled.

894,479. INDUCTION COIL. Amos R. Bliss, Lowell, Mass. The secondary winding is composed of units each consisting of a coil of wire wound on a spool provided with external contact members.

894,482. PLATING MACHINE. Seth C. Catlin, Bloomfield, N. J. A rocking plating tank.

894,518. LIGHTNING ARRESTER. Maurice Milch, Nagy Bittse, Austria-Hungary, assignor to General Electric Company. A plurality of conductors of different material disposed to form a series of air-gaps having greater resistance to the flow of current in one direction than in the other.

894,522. VOLTAGE-REGULATING SYSTEM. Wilbur L. Merrill, Schenectady, N. Y., assignor to General Electric Company. A plurality of counter-electromotive-force generators, each controlled by a separate rheostat, is employed.



894,318.—Aerophore.

894,533. DYNAMOELECTRIC MACHINE. Henry G. Reist, Schenectady, N. Y., assignor to General Electric Company. A binding band comprising a metal strip having holes therein and clips acting as fan blades.

894,539. REGULATION FOR MULTIPHASE SYSTEMS. Edward Schildhauer, Washington, D. C., and Albert A. Radtke, Chicago, Ill. A regulating generator is connected in each phase of the main supply circuit, all the auxiliary machines being mounted on one shaft.

894,547. APPARATUS FOR MANUFACTURING NITROUS COMPOUNDS. Charles P. Steinmetz, Schenectady, N. Y., assignor to General Electric Company. Electric arcs are drawn out in an enclosed air chamber.

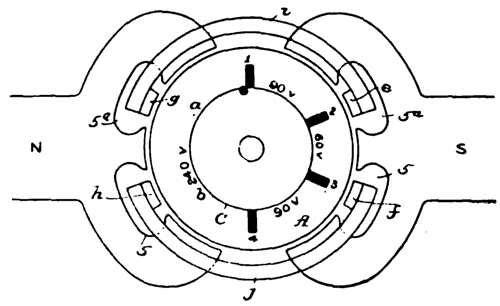
894,563. STARTING RHEOSTAT. William C. Yates and George W. Cravens, Schenectady, N. Y., assignors to General Electric Company. Means are provided for rendering neutral a switch having a tendency to return to the off position.

894,564. RHEOSTAT. William C. Yates, Schenectady, N. Y., assignor to General Electric Company. A reversing rheostat which normally returns to the off position, but which can be held in any position when desired.

894,565. RHEOSTAT. Paul H. Zimmer, Schenectady, N. Y., assignor to General Electric Company. A rheostat with an overload switch.

894,602. SECONDARY OR STORAGE BATTERY. Charles H. Clare, Stratham, N. H. An element having an assemblage of electrodes, active material and plates for supporting the latter, with an opening for receiving and holding an exciting fluid.

894,614. RHEOSTAT. George H. Gorgeloh, Schenectady, N. Y., assignor to General Electric Company. A combined armature and field rheostat.



894,329.—Electric Generator or Motor.

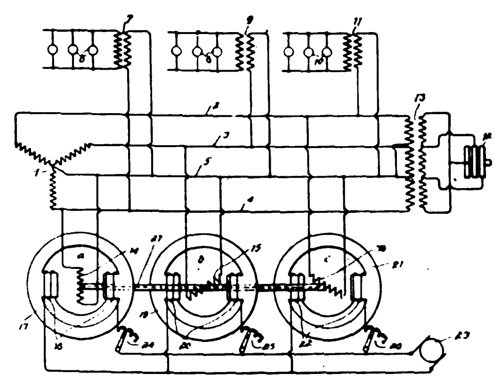
894,620. TRANSFORMER. John J. Frank, Schenectady, N. Y., assignor to General Electric Company. A combined step-up and step-down transformer, the latter having its primary and secondary windings spaced apart.

894,625. INCANDESCENT LAMP. Emery G. Gilson, Schenectady, N. Y., assignor to General Electric Company. The tubular members for supporting the filament are sealed with metal caps.

894,637. TROLLEY CONTACT. Laurence A. Hawkins, Schenectady, N. Y., assignor to General Electric Company. A long, flat, flexible strip of metal.

894,643. CONTACTOR. George H. Hill, Schenectady, N. Y., assignor to General Electric Company. An electromagnetic switch.

894,644. BUS-LINE COUPLING SOCKET. George H. Hill, Schenectady, N. Y., assignor to General Electric Company. The socket member of the coupler is of insulating material having a terminal projecting from the bottom of the cup.



894,539.—Regulation for Multiphase Systems.

894,645. CONTACTOR. George H. Hill, Schenectady, N. Y., assignor to General Electric Company. An electromagnetic switch operated by a coil and plunger magnet.

894,651. METER. Charles E. Holmes, Lynn, Mass., assignor to General Electric Company. An induction meter.

894,668. SYSTEM OF ELECTRICAL DISTRIBUTION. Osias O. Kruh, Schenectady, N. Y., assignor to General Electric Company. A combination of a mercury rectifier and transformer.

894,714. VARIABLE-VOLTAGE TRANSFORMER. Mercer G. Young, Pittsfield, Mass., assignor to General Electric Company. Means are provided for varying a portion of the primary flux which passes through the secondary winding.

894,766. MEANS FOR OPERATING VAPOR ELECTRIC LAMPS. Ezechiel Weintraub, Schenectady, N. Y., assignor to General Electric Company. A plurality of vapor electric lamps connected in series with one another.

CONTENTS

PREVENTING VIBRATION.

Sometimes it happens that an engineer is called upon to prevent vibration of a building or apparatus, caused by neighboring machinery. Many can recall the annoyance and trouble experienced during their college days, when working in a physical laboratory near a street along which heavy vehicles traveled, or even due to the operation of some piece of apparatus in another part of the same building. Various plans have been devised for preventing this trouble, the simplest possibly being to mount the galvanometer or other instrument on a block of stone supported in a box of sawdust. Under the right conditions the motion of the pedestal or table upon which the box is supported is absorbed in the sawdust, so that the galvanometer remains comparatively quiet. Sometimes the instrument can be supported on a light board carried on rubber bands, with good results. Probably the most satisfactory arrangement is that known as the "Julius Suspension," in which a system of springs and weighted supports, adjusted so as to avoid any harmonic swaying which might be set up, carries the instrument. This device, however, is somewhat expensive and elaborate, and is not available at every point.

It occasionally happens that annoyance is caused in other quarters than the physical laboratory by the operation of machinery. Sometimes, under unfavorable conditions, this annoyance becomes serious. An interesting example of this was noted in the ELECTRICAL REVIEW for August 8, in which the running of the reciprocating engines driving generators in the central station of the township of Sutton, England, gave rise to so much complaint that it was decided to change the type of equipment. This decision was not reached until other means of avoiding the trouble seemed to have been exhausted. Deep trenches were dug around the power-house, going well down below the engine and house foundations; but as both engines and houses were on the solid chalk, this plan, as might have been expected, failed. It was therefore decided to adopt steam turbines, which it was thought would not be as objectionable, as vibration should be less; but, in addition to this, special arrangements were made to absorb any vibration which might arise in the turbines. The plan adopted was quite similar to the arrangement resorted to in the physical laboratory. The turbine was set on a solid block of concrete, which was, in turn, supported on rubber cushions. In this case, of course, it is the vibrating device which is cushioned, and not the object which it is desired to protect. The result, of course, is the same, but it is interesting to note that the plan would not have been feasible for any present type of prime mover, except the turbine. It is true that well-balanced reciprocating engines are frequently run without being bolted solidly to their foundations, but few engine builders or operating engineers would be willing to trust these engines on a flexible support such as cushions of rubber.

While on this subject of vibration it is rather interesting to call attention to the recent improvement in the running conditions of the steamship "Mauretania," which, it will be remembered, is driven by four steam turbines, and which recently damaged one of her propellers. While repairing the latter advantage was taken of the opportunity to change the propeller blades a little, and it is said the change reduced very appreciably the vibration of the vessel. It seems that there was more or less resonance between the vibration caused by the propeller blades and the speed at which they were driven; so by throwing the two out of harmony, the effect is damped out. Doubtless similar conditions exist elsewhere and frequently are the cause of the entire trouble due to vibration, and by some slight change, throwing the apparatus or its support out of tune, the effect is removed.

ELECTRICAL SMELTING OF IRON.

The greater part of the efforts to apply the electrical furnace to the production of iron in its various forms has been in the direction of making special kinds of iron and steel. For such purposes a somewhat higher cost of production is not prohibitive, since the special character of the product brings a good price. In the electric furnace the treatment can be brought so thoroughly under control that any special character or quality of product is more surely produced. And at a time when steel capable of use under extraordinarily severe conditions is demanded, such, for example, as cutting metal while the tool is red hot, the commercial application of a method of production which, under present conditions, is somewhat expensive has been possible. Recognizing this condition, electro-metallurgists have been largely content to supply the present requirements, and to leave to a later day the development of an electric furnace for smelting the ore.

Not all investigators have, however, been content with the most obvious application of the electric furnace to the metallurgy of iron, as some have sought to use it for the reduction of special ores which are not profitable to treat in the usual blast furnace. Others again have sought to devise a plan by which the energy of waterfalls might be utilized, in places where fuel is expensive, and thus start an iron industry in countries where lack of coal at present prohibits it; such, for example, as Sweden and Italy, where attempts have been made to reduce iron ore in electric furnaces; and also in Canada, where some rather elaborate experiments were carried out not long since. It is certain that the results of these experiments, which have been made public, seem to be favorable to the processes, but they have been generally considered rather too optimistic. It has been shown that iron can be produced from the ore in an electric furnace, which no one disputes, but the conditions under which the various tests were conducted make it somewhat difficult to determine accurately the cost of production by each process. In each case it becomes evident that the electric furnace can only compete with the blast furnace when the cost of electrical energy is much less than what it is sold for anywhere to-day. Hence certain of the reports of such tests devoted a good deal of attention to the question of power production, and in the Canadian reports and those of the work in Sweden, it was said that an electrical horse-power-year could be produced for $8 or $10, or even less.

The most recent attempts to smelt iron in an electric furnace are those which have been made during the present year in California. After preliminary experiments at the Lewis and Clark Exposition, a furnace of the Heroult type was built last year by H. H. Noble, in California, to determine whether it was commercially practicable to apply electric smelting for the production of iron from the California ores. This furnace was somewhat large, requiring when in full operation about 1,500 kilowatts, the power being supplied by the Northern California Power Company. Iron was produced, but the output of the furnace was considerably less than had been expected, and the power-factor was low, being only seventy-three per cent. Moreover it was found impossible to work the furnace continuously at full capacity.

The work was then taken up by Mr. G. H. Clevenger and Professor D. A. Lyon, who constructed a small furnace requiring only 160 kilowatts, but the design of which was intended to avoid the objections of the larger furnaces. A steel casing was not used, so as to keep the power-factor high; and a design resembling more nearly a blast furnace was adopted, with the expectation that this type could be run continuously, and a good part of the heat given off would be saved by using it to heat the cold charge as it moved slowly down the stack. The results of these experiments are given in a brief abstract elsewhere in this issue. They seem to be unexpectedly good, but still leave the question of the commercial value of the process at the present time in doubt.

The performance of this furnace as regards power consumption does not seem to be as good as that of the larger Heroult furnace; for the latter, it is said, produced a ton of iron with an expenditure of 0.26 kilowatt-year, while the latest furnace required about 0.35 kilowatt-year. This figure includes, it should be noted, the energy required for the preliminary heating of the furnace; and since the furnace can be run continuously for months at a time, a slightly lower energy consumption is to be expected. It is estimated that for a large furnace operating without intermission, the energy required to produce a ton of pig iron will be about 0.31 kilowatt-year. The power-factor of the furnace is said to be ninety-five per cent, and by varying the applied voltage the heat energy developed at any time is under complete control.

In the article referred to above, the author, Mr. C. F. Elwell, attempts to determine what will be the cost of producing pig iron in a furnace of the type just referred to, but large enough to produce fifteen tons a day. Such a furnace would require about 1,500 kilowatts, and the daily cost of operation would be $207.10. This includes everything. Electrical energy is charged for at $5 per ton produced, or at about the rate of $16 a kilowatt-year or $12 a horse-power-year. The cost of a ton of pig is found from these figures to be $16.14.

At this figure of $16.14 per ton of pig, it would seem that the furnace can be applied successfully only under special conditions: it can not compete with the large blast furnaces. Moreover, the price of $16 a kilowatt-year can be secured in very few localities; and an addition of $4 to the cost, bringing it up to, say, $20 per kilowatt-year, would bring the cost of the pig iron to about $17.50 per ton. Another difficulty is the comparatively small size of the furnace, as it produces only fifteen tons a day. This objection will doubtless be overcome by the construction of still larger furnaces, after more experience has been obtained. It might be found, indeed, that there is less need to go to such sizes as are customary in blast-furnace work.

On the other hand, it is urged, in favor of the electric furnace, that it costs little to install, is simple and easily controlled, repairs are not expensive, a breakdown is not fatal, and the quality of the output is under better control. The most important advantages, however, are the substitution of the energy of waterfalls for that of coal, in locations where fuel does not exist, and the ability to smelt ores which are valueless for blast furnaces. From what has already been done it does not seem to have been shown that the electric furnace can enter immediately into competition with the blast furnace, but it must not be overlooked that the price of fuel is constantly rising, and the work of adapting the electric furnace to smelting iron ores has only been begun. Although the process may not be commercial to-day, it is well worth further study.

TELEGRAPH STATISTICS.

Telegraph statistics for various countries are made public from time to time, but it is not often that a compilation showing conditions in the various countries at one time is possible. Such a compilation has, however, been made by the German Government. The figures which it shows are interesting, not only as indicating the enormous use of this means of communication, but as showing the differences existing in telegraph conditions among the several countries. The most striking figures are those for this country, Germany, the United Kingdom and France. We lead in the extent of our telegraph lines, but only come second in their use, due no doubt to the difference in rates existing here and abroad. In England, for example, there are about 94,000,000 messages annually, while we send only 65,500,000. France comes next to us with 58,000,000, with Germany close behind with 52,500,000. The income from the use of the telegraph in this country is estimated at $27,985,000, as against $15,247,000 in the United Kingdom. Thus, although fewer messages are sent in this country, the considerably higher average rate, due, of course, not only to the higher rate for similar service, as compared with other countries, but to the greater distances over which messages are sent, brings the total expenditures for messages above that for other countries. Thus the average rate in England is sixteen cents for a message, while in this country it is forty-two cents. In Germany the rate is lower even than in England, being only fifteen cents, and it is still lower in France, where it is twelve cents. The total receipts of the telegraph service in Germany are $8,299,000, and in France, $7,334,000. In the three foreign countries considered the service is rendered by the governments, and in this country alone is it given by private companies.

ELECTRICALLY PROPELLED FERRY BOATS.

Some years ago we suggested that a very acceptable application of the electrical drive might be on the many ferry boats which furnish transportation between the island of Manhattan and the neighboring cities. The idea was to install storage batteries of suitable capacity on the boats, and to charge these fully during periods of rest and as much as possible in the intervals between trips. The service would possibly be rather hard on the batteries, as the idle periods are short and most of the time is spent in making the runs; but when all of the suburban traffic, as well as that within the city itself, is transported electrically, it seems as though the connecting link above water should be operated in the same way. For the service through the many tunnels now in operation or under construction beneath the two rivers flowing on either side of the island, no other system of propulsion was contemplated. However, no movement has yet been made in this direction toward converting the ferry boats—indeed, the tendency seems to be to abandon the ferries at New York, and depend entirely upon the tunnels and bridges. The scheme has, however, been adopted in Germany, where an electrically propelled ferry boat has been fitted up for service on the route between Godesberg and Niederdollendorf. This boat will carry about 650 passengers. Further details of the service are not at hand; but it is to be presumed that it will not be as severe as would be the case at New York. Thus again have our German friends become the pioneers in an interesting electrical adaptation.

AN ELECTRIC MOTH-TRAP.

According to dispatches which have been noticed in several daily papers, the municipal authorities of Zittau, in the province of Saxony, Germany, have made capital use of electric searchlights in reducing the damage created by a pest of nun moths which have been ravaging the trees of the valley of their foliage, threatening some of the more densely planted sections with destruction. The scheme apparently is to use a large induced-draft fan in connection with a high-power arc and reflector. The moths are attracted along the beam of light and, getting in proximity to the reflector, are drawn by the suction of the fan into a chamber and destroyed. It is stated that on the first night no less than three tons of moths were caught.

THE TEST-METER METHOD OF TESTING SERVICE METERS—II.

BY JOSEPH B. BAKER.

THE MOWBRAY TEST METER—FIRST FORM—OBJECTS OF DESIGN.

W. J. Mowbray, in a paper entitled "The Testing of Meters on Consumers' Premises by Means of a Specially Constructed Watt-Hour Meter," read before the 1902 convention of the Association of Edison Illuminating Companies, described a form of portable test meter[1] of the commutator type, in the construction of which it was sought to eliminate the defective features of existing forms of this apparatus that were mentioned in the preceding article. This form of test meter consisted of a standard test-recording wattmeter with the register removed, and with several simple modifications designed to facilitate the connecting and manipulating of the apparatus and to eliminate the sources of error already mentioned to which the ordinary integrating wattmeter is liable when used as a portable test meter.

SPECIAL HIGH-TORQUE FIELD-WINDING.

The principal feature of the Mowbray test meter, which is shown in the accompanying views, Figs. 1 and 2, is a composite field-winding made by adding a second pair of field coils to the existing fields of the meter as received from the manufacturer. The object of this composite field is to eliminate the first-mentioned source of error by enabling the torque of the test meter to be increased for a given load constituting a light load on the meter under test.

In a recent communication to the writer Mr. Mowbray makes the following statement:

"Hearing of the above method [of testing by the use of a portable standard meter], and recognizing the disadvantages just cited, I conceived the idea that a test meter with a plurality of field-windings would eliminate the light-load error in testing. For example, if a test meter were constructed with a ten-ampere winding and also a one-ampere winding, and used to check a consumer's meter of ten-ampere capacity, on full load the ten-ampere fields of both would be connected in series and an accurate full-load test would be obtained—the same as by the original method. However, on light load—one ampere—we would make connections with the one-ampere field of the test meter, and the latter would run at full torque, speed and accuracy; and would, if the consumer's meter happened to be correct, make ten revolutions while the consumer's meter made one revolution. Thus the error on light-load tests was eliminated.

"It was found possible to make not merely a one and ten-ampere test meter,

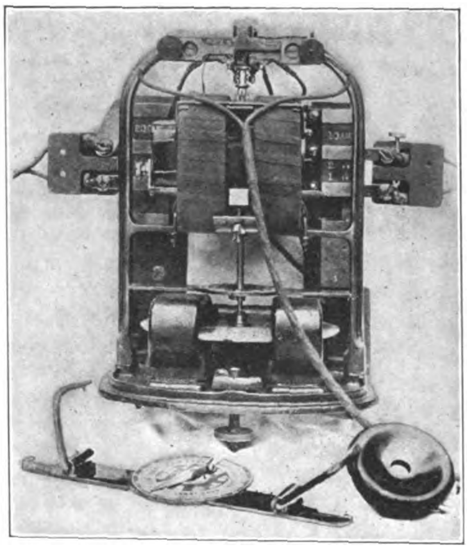

Fig. 1.—Mowbray Test Meter.

but a one, four, sixteen and eighty-ampere meter, and it was obvious that such a meter would suffice to test all sizes of consumers' meters, from three to 150 amperes' capacity, especially as it was wound

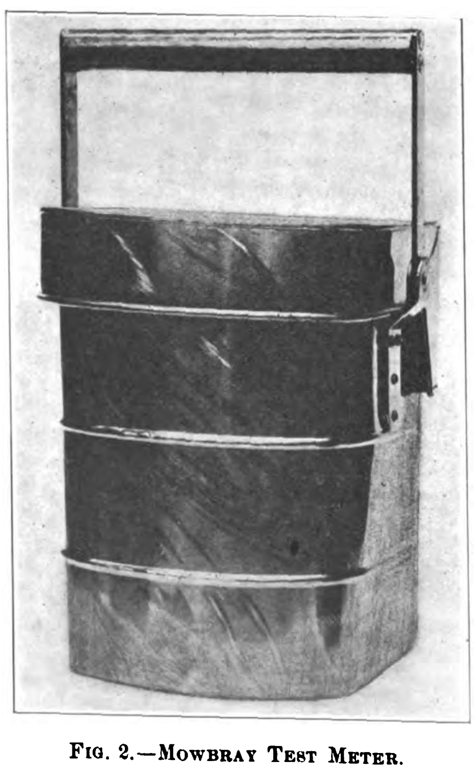

Fig. 2.—Mowbray Test Meter.

to give a very high torque, enabling each winding to be used with accuracy from one-half to one and one-half rated load. The old method of comparing the revolutions by sighting from one disc to the other evidently could not be used, as consumers' meters run in sizes such as three, three and one-half, five, seven and one-half, ten, fifteen, twenty-five, seventy-five, 100, 150, etc., and would not all run at the disc speeds given by the one, four, sixteen and eighty connections of the test meter. For this reason the method of comparison by two stop-watches, in the hands of two men, was temporarily used."

This feature may be illustrated by a concrete example. In the ten-ampere size of the test meter, which is initially a regular ten-ampere, 115-volt, two-wire test-recording wattmeter, the additional field-winding, placed outside the original ten-ampere fields, consists of a pair of coils wound with No. 20 B. & S. wire, giving the same number of ampere-turns for a current of one ampere as are given by the regular fields for a current of ten amperes. By connecting up this composite field-winding in various ways, three different field strengths—or "scales," as they have been termed in analogy to the various scales of an indicating ammeter, for example—giving correspondingly different torques for the same load through the meter, are obtained as follows:

A one-ampere scale, obtained by connecting the one-ampere field-coils in series.

A two-ampere scale, obtained by connecting the one-ampere field-coils in multiple.

A ten-ampere scale, obtained by connecting the ten-ampere field-coils in series.

The different field strengths, or "scales," obtained in this way constitute an important feature of the test meter. As in an (indicating) ammeter, a choice of several scales facilitates the obtaining of accurate *indications* on different loads, so in the recording wattmeter, equipped as described with means of obtaining different torques for a given load, accuracy of *integration* of the power passing through the meter is facilitated by the ability to make a light load give a strong torque, thus minimizing the effect of variation in friction or vibration. By always connecting the test load through a suitable scale or field of the test meter, the latter is always run at full-load conditions of torque and accuracy, even for light load on the meter under test—never at an ordinary low torque which would admit errors due to friction.

The test meter is, in fact, an apparatus of the rotating-wattmeter type especially designed to secure positiveness of operation on small loads, and thereby accuracy of integration of such loads, at the sacrifice of mere motor efficiency; the excessive energy required to give the abnormal positiveness consumed in each of the very small number of test meters that might be

[1] See the following references in the *Electrical World and Engineer*:

in use on the central station system at a given time being of negligible importance compared with the object in view.

Returning to our concrete example: It is generally known that the accuracy of the Thomson meter is practically independent of ordinary changes in friction and vibration on loads exceeding one-half its rated capacity, and that it will carry twenty-five per cent overload for a considerable time without introducing serious errors due to heating. In other words, that portion of its accuracy curve from fifty to 125 per cent of its rated capacity is very nearly a straight line.

RAPID WARMING UP OF POTENTIAL CIRCUIT.

Another advantage of the direct-current test meter as compared with an ordinary standardized meter used for testing purposes, and logically to be referred to in connection with the composite field construction, is the facility provided for rapid warming up of the potential circuit to normal running temperature, thereby avoiding the second-mentioned source of error. The potential circuit of the ordinary direct-current meter, consisting of armature and resistance in series, must be connected to the supply mains for at least fifteen minutes in order to attain normal temperature and therefore normal resistance under running conditions. In the test meter provision is made for rapid warming up by having two potential circuits, or "scales," for 115 volts and 230 volts, respectively. The 115-volt potential circuit consists of the standard ten-ampere, 115-volt, two-wire meter armature, in series with an ordinary adjustable shunt having 1,200 turns and approximately 450 ohms resistance. The 230-volt potential circuit consists of this armature and shunt in series with a resistance card of resistance at normal working temperature equal to that of the armature and shunt. This extra card is wound with tinned iron and German-silver wire in the proportion of seventy-six and one-half per cent of the former to twenty-three and one-half per cent of the latter, the proportion used regularly by meter manufacturers in order to get a potential circuit having a temperature coefficient equal to that of the metal of which the meter disc is composed. By connecting the 230-volt scale to the 230-volt mains, a period of only one and one-half minutes is required to bring the resistance of the circuit up to normal running value; or if this double voltage is not available the same object may be attained by connecting the two potential scales, in parallel, to the 115-volt mains. By this means the inspector can get his test meter into accurate running condition with entire avoidance of error due to "cold potential circuit," with minimum loss of time.

The inductance of these potential circuits is stated by the inventor to be sufficient to introduce some error, requiring to be compensated for, when the test meter is to be used on alternating-current loads.

The connecting of the test meter on the correct polarity, to avoid the third source of error, is of considerable importance owing to the existence in the test meter, as in other forms of direct-current motor meters, of a flux composed of (a) the compensating coil flux, and (b) the stray field from the braking magnets, which exist notwithstanding the care taken in the factory to equip the meter with magnets of equal strength, symmetrically disposed.

The correct poling of the compensating coil of a meter, *i. e.*, the way it is poled when sent out from the factory, is that poling which gives a flux through the armature in the same direction as the stray field from the system of magnets, thereby producing a stronger tendency for the meter to creep than when the compensating coil's flux is opposed to the magnets' stray field. The correct poling of every meter is therefore that which gives the greater tendency to creep. In the communication already referred to Mr. Mowbray states that in the operation of calibrating his test meter an abnormally large current is passed through the fields, thereby distorting the distribution of flux from the braking magnets and making component (b) of the no-load flux abnormally large, so as to give the test meter a very decided "polarity," which should be followed at all times in connecting up the test meter.

The correct poling of the test meter is most readily determined during the heating up of the potential circuit by touching the potential leads to the source of potential first one way and then reversed. As the potential circuit during the heating is on double voltage, the current in the armature and compensating coil is twice as strong as under normal running, hence the difference in rate of creep on reversing the potential leads at the source of potential will be very great; so that the operation of determining the correct poling of the potential circuit takes only a few moments. After the heating is done, and as the load is being connected through the fields, it is only necessary to connect the load so that the test meter rotates in the forward direction to be assured that its polarity is correct.

Prior to this method of determining the correct polarity of the test meter, an ordinary electrolytic "pole tester" was used. Its use was superseded by the above method, not only on account of its troublesome operation and liability to cause short-circuits, but mainly because in case the no-load flux of the test meter became reversed, its use insured that the meter was always connected on the wrong polarity. For example, it sometimes happens that a careless tester will momentarily connect a heavy load to a low-value field-winding, and if the current happens to be in the wrong direction it will reverse the polarity of the test meter. The indication of the "pole tester" would give the wrong poling of the test meter; whereas the mere reversal of the connections to the test meter, after such accidental reverse overload, would insure that the compensating coil's flux and the stray field from the magnets were in the same direction.

Another plan to indicate the polarity (now also superseded) was to mount a small compass near the field coils and follow its indications by poling the meter so that the S end of the needle pointed to the coils. This device was open to the same objection as the "pole tester," and it also had a fault of its own, *viz.*, that if the needle happened to be caught in a certain position when the current was applied to the fields it would be reversed.

(To be continued.)

An Electric Moth-Trap.

The Saxony authorities have discovered what would seem to be an excellent way to put an end to the caterpillar plague which is having such a disastrous effect on the local forests. They have discovered a method to catch the brown nun moths that lay the eggs from which the caterpillars come in enormous quantities. They make use of what they call the electric light trap. This consists of two large and powerful reflectors placed over a deep receptacle and powerful exhaust fans. The whole has been erected on top of the municipal electric plant at Zittau. At night two great streams of light are thrown from the reflectors on the wooded mountain sides half a mile distant.

The results have been astonishing. The moths, drawn by the brilliancy, come fluttering in thousands along the broad rays of light. When they get to a certain distance from the reflectors the exhaust fans take up their work and with powerful currents of air swirl them down into the receptacle. On the first night no less than three tons of moths were caught. It has been decided to build another trap on the Rathaus Tower, and the fight with the moths will be continued.

The forests of central Europe have, from time to time, been ravaged by raids of moths from Russia, whose larvæ denude the trees of their foliage. The splendid pines of the Lausitz Mountains are this year threatened with destruction.

The Reduction of Iron Ores by Electricity.

A discussion is given in the issue of July 18 of the *Journal of Electricity, Power and Gas*, San Francisco, by C. F. Elwell of the attempts to reduce iron ore in an electric furnace which have been made recently in California. After a brief historical introduction the author takes up the California work. This was instigated by experiments made by Dr. David T. Day for the United States Government at the time of the Lewis and Clark Exposition, Portland. A furnace of the Héroult type was constructed, controlled by varying the voltage. This control was found to be satisfactory, but no quantitative results were obtained. After Dr. Day's return to Washington the work was taken up by G. H. Clevenger, of Leland Stanford, Jr., University. In July, 1907, H. H. Noble, of the Northern California Power Company, looking for a market for some of the power developed by his company, retained Dr. Héroult to design and build a furnace for smelting iron ore of the Shasta Iron Company. A 1,500-kilowatt, three-phase furnace was built and put into operation. It consisted of a steel shell thirteen feet long and five feet six inches wide, lined with brick. Three electrodes were suspended above it, on a plan similar to that adopted at the Soo. The bottom was of carbon, and formed the neutral point of the three-phase star connection of the furnace. It was confidently expected that this furnace would produce twenty-four tons of iron a day. However, the largest production was only eleven tons a day, and it was found impossible to run the furnace for any length of time. The electrodes were exposed to the air and were consumed rapidly, and due to the open construction of the furnace the heat was unbearable, so that men refused to work. The thermal efficiency of the furnace was good, as but 0.26 kilowatt-year was required per ton; but the furnace would not produce enough iron at that figure to make it pay, one reason being the low power-factor, which is seventy-three per cent, and another the inability to keep full power on the furnace all the time. In January of this year Mr. Clevenger, co-operating with Professor D. A. Lyon, constructed a 160-kilowatt, single-phase furnace. The stack is of concrete, twenty-nine feet high. The electrodes are fixed in the walls of the crucible, and a variable-voltage transformer is used to keep full power on the furnace at all times. The charging is done from the top, so that the long column of charge is effectually preheated before it reaches the zone of fusion between the electrodes. The latter are twenty-four inches apart. The crucible is lined with fire-brick, and water-cooled. The metal tap hole is a water-cooled casting, but the slag tap hole is not cooled. Current is supplied by means of a 160-kilowatt, variable-voltage transformer, supplying from sixteen to ninety-six volts, in twenty steps. The highest potential is used at starting. When running normally, the voltage is about thirty-five, and the current 4,000 amperes. Up to the present time, six runs have been made, varying in length from ninety to two hundred and seventy-nine hours. The lowest figure for a run was 0.35 kilowatt-year per ton of pig. This includes the preheating of the crucible before any charge is put into it. This preheating of the crucible takes current for about twenty-four hours before smelting is commenced. This charge will become insignificant in a furnace which will run for three or six months without being shut down. Plans are now being drawn for a 1,500-kilowatt furnace similar to the one just described. This, however, will use three-phase current. The author then discusses some of the problems presented in designing an electric smelting furnace. The rate of heat production necessary to maintain a given temperature in the furnace depends upon the thickness and the conductivity of the walls. An analysis of furnaces which have been built up to this time shows a fair uniformity, which may be stated to be from seven to fifteen kilowatts per cubic foot of crucible. Sometimes it is difficult to determine just what constitutes the crucible. The lining must be adapted to the character of the ore, a basic brick being used with basic slag. The brick must be efficiently cooled, or it will not last for any length of time. Care must be taken in the arrangement of the water jackets, or electrical difficulties will be met. The bricks at high temperatures become good conductors of electricity. The power-factor of the 160-kilowatt furnace just described was ninety-five per cent. A good deal, however, depends upon the layout of the bus-bars carrying the large currents to the furnace. There is difficulty in securing electrodes which will stand the service. Those giving the most satisfaction have been manufactured by the Héroult process. They are usually sixteen inches square and six feet long. An electric furnace can compete successfully with a blast furnace only where water power is cheap and coal dear. Assuming a heating efficiency of twenty-five per cent for fuel, and seventy-five per cent for electric heating, then electricity is cheaper than coal only when one ton of coal costs more than half the cost of an electric horse-power-year. The author estimates that the running cost of a 1,500-kilowatt furnace, producing fifteen tons a day, would be \$204.60, or \$13.64 per ton. Allowing \$2.50 for incidentals brings the total cost to \$16.14. The cost of energy is estimated at \$5 for each ton produced. The consumption allowed for is 0.31 kilowatt-year per ton. The method of operating the furnace consists of first filling it to the top with previously heated coke, which is a conductor. By applying a low voltage the temperature can be gradually increased. After twelve hours the first charge is fed in, consisting of iron ore, lime and andesite. This is put in at the rate of a shovelful every four minutes, and after it is all in the regular charge is commenced. It may consist of 1,000 pounds of iron ore, 253 pounds of charcoal, 100 pounds of lime and 160 pounds of andesite, which is fed in rapidly at first, so as to get a column of charge in the stack. After four hours the furnace is tapped and a part of the iron drawn off. A proper amount of slag is maintained by drawing off occasionally from the slag tap hole. The advantages given for this type of furnace are the original small cost of the furnace and the absence of bulky and costly charging machinery, the small expense involved through breakdowns, the small cost of repairs and the ease with which they may be made, the loss due to wrong composition of charge is reduced to a minimum, the quality of iron is much better, high-sulphur ore can be converted into low-sulphur pig, there is no danger of the formation of cyanides due to the presence of nitrogen, and the silicon in the iron may be varied as required. It is said that ore containing as much as one and one-half per cent of sulphur can be reduced successfully in the electric furnace.

Street Railways in England.

There are 2,391 miles of street railways in England, an increase of 1,330 miles in the past ten years. In that period the capital expenditure per single mile of track has increased from £10,469 to £16,618, while the ratio of expenditure to receipts has decreased from 76.93 per cent to 62.11 per cent, and the average fare per passenger from 1.23*d.* to 1.1*d.*

COPPER PRODUCTION IN 1907.

ADVANCE STATEMENT BY UNITED STATES GEOLOGICAL SURVEY.

The smelter production of copper in the United States in 1907, according to L. C. Graton, of the United States Geological Survey, was 868,996,491 pounds. From the record figures of 1906 this is a decrease of 48,809,191 pounds, or 5.6 per cent, the largest actual decrease ever recorded and the largest relative decrease since the American copper industry became important. This is the first time since 1901 that the annual production has been smaller than that of the preceding year, and the first time since 1872 that it has been smaller than that of the second year preceding.

The total given above is made up of the fine copper content of blister produced and of the smelter output of ingot and anode copper from Michigan. Of this quantity, approximately 10,075,048 pounds in blister were produced in foreign smelters from domestic materials exported. In addition to the domestic materials handled, smelters in this country turned out as blister 64,145,648 pounds from foreign ore, concentrates and matte. Domestic blister containing 42,350,963 pounds was exported unrefined, while blister from foreign sources containing approximately 183,530,132 pounds fine copper was imported for refining in this country.

The greatest decreases in smelter output are shown by the returns from the three states that rank highest. Montana's production, which was 294,701,252 pounds in 1906, was but 224,263,789 pounds in 1907, and the state yielded first place to its rival, Arizona, whose production, however, showed a decrease of nearly 6,000,000 pounds, from 262,566,103 pounds in 1906 to 256,778,437 pounds in 1907. Michigan still holds third place, with its production decreased from 229,695,730 pounds in 1906 to 219,131,503 pounds in 1907. Decreased production is also shown by the returns from Alaska, Oregon, Washington and North Carolina.

Many of the other copper-producing states showed substantial gains. The output of Utah, the fourth state in point of production, was nearly 16,000,000 pounds in excess of that of 1906—66,418,370 pounds in 1907 as against 50,329,119 pounds in the preceding year. The production of California increased from 28,153,202 pounds in 1906 to 33,696,602 pounds in 1907; that of Colorado from 7,427,253 pounds in 1906 to 13,998,496 pounds in 1907; that of New Mexico from 7,099,842 pounds in 1906 to 10,140,140 pounds in 1907, and that of Idaho from 8,578,046 pounds in 1906 to 9,707,299 pounds in 1907. Nevada and Vermont also showed productive gains.

REFINED COPPER.

The production in 1907 of refined new copper of domestic origin was 784,271,427 pounds, a decrease of 103,410,960 pounds, or 13.2 per cent, from the production of 1906. The total output of refined copper (exclusive of domestic scrap, etc.) by domestic refineries in 1907 was 1,032,516,247 pounds. In addition to this production of refined copper 25,129,617 pounds were recovered during the year by the regular copper-refining companies of the country from domestic scrap, drosses, etc., and returns from practically all the known refiners of secondary materials indicate that 35,355,966 pounds additional were turned out by them as casting copper and in alloys. The copper produced from secondary sources in 1907 was therefore somewhat in excess of 60,000,000 pounds, or more than 7.5 per cent of the year's production of refined new copper.

STOCKS.

Returns from all the Lake and electrolytic refiners are practically complete and show the following stocks of refined copper on hand at the beginning and end of the year:

	Pounds.
January 1, 1908	125,745,796
January 1, 1907	46,497,181
Increase during 1907	79,248,615

Undelivered sales are almost entirely excluded from these figures, and stocks carried by consumers and brokers have not been estimated. In addition to these stocks of refined copper there were at the smelters, in transit to the refineries, and at the refineries blister copper and material in process of refining to the amount of 135,310,239 pounds on January 1, 1907, and 175,254,659 pounds on January 1, 1908.

CONSUMPTION.

The apparent consumption of refined new copper in the United States in 1907 was about 485,000,000 pounds, as compared with 685,000,000 pounds in 1906, and it is probable that in addition most or all of the 60,000,000 pounds of reworked copper was consumed.

The figures given above are compiled by Mr. Graton from the exact records of all but one known producing company. A comprehensive report on the copper industry in 1907 is in preparation and will be published by the Geological Survey as an advance chapter from "Mineral Resources of the United States, Calendar Year 1907." The preliminary statement herewith presented is made in advance to meet a demand for official figures at the earliest possible date, covering the two most important statistical features of the industry—production and consumption. So far as is known at present, no revision of the figures will be necessary, but the right is reserved to make in the complete report any slight reapportionment that final analysis of the figures may require.

The Arkansas Association of Public Utilities Operators.

The first annual convention of the Arkansas Association of Public Utilities Operators will be held at Little Rock, Ark., September 17 and 18. This association was formed at Little Rock, July 17 and 18. The purpose of the organization is the mutual benefit of the members and the advancement and development of public service corporations in Arkansas. The membership of the association has been classified as follows: Class A members are operators and executive officials of public service corporations. Only this class of member has a voice in the executive business of the association. Class B is composed of salesmen representing supply and jobbing companies selling to the gas, electric and water utilities. Class C is composed of honorary members who, while they may not be directly identified with a public utility corporation, take an interest in such concerns.

The following officers have been elected:

President, D. A. Hegarty, general manager of the Little Rock Railway and Electric Company.

First vice-president, G. B. Harpole, general manager of the Batesville Water and Light Company.

Second vice-president, W. H. Walkut, Searcy Electric Light Company.

Third vice-president, J. M. Hewett, president of the Marianna Lighting Company.

Secretary, J. E. Cowles, superintendent of lighting, Hot Springs Light and Railway Company.

Treasurer, D. L. Ellis, general manager of the Camden Lighting and Power Company.

Executive committee—the president, secretary and the following: Edwin Hardin, superintendent of railways, Hot Springs Light and Railway Company; W. C. MacGuire, superintendent Wilson Water and Electric Company, Arkadelphia; S. A. Stearnes, general manager Home Water Company, Little Rock.

Brooklyn Edison Company Dines Electrical Men.

The annual dinner tendered by the Edison Electric Illuminating Company of Brooklyn to the electrical contractors of the borough of Brooklyn, New York city, was held on the pier at "Dreamland," Coney Island, Tuesday evening, August 4. Two hundred guests were present. W. W. Freeman, vice-president and general manager of the company, was toastmaster. Among those who made addresses were: T. C. Martin, C. A. Christensen, president of the Independent Electrical Contractors' Association of Greater New York, and A. S. Beach, president of the Long Island Electrical Contractors' Association.

In his address of welcome to the contractors Mr. Freeman stated that the company had increased its business very largely during the past year. The contracts held by the company for the seven months ended July 31 showed that 317,000 sixteen-candle-power lamps had been used, as against 298,000 during the same period in 1907.

A suggestion had been made concerning the organization of a club of the electrical contractors, and all those directly or indirectly interested in the electrical business, to be known as the Kilowatt Club. Mr. Freeman stated that at an early date a meeting would be called for discussing the formation of such an organization.

M. S. Seelman, Jr., manager of the publicity department of the Edison company, was chairman of the dinner committee. Among those present and the concerns represented at the dinner were the following:

Acme Electric Construction Company, Alzman Brothers, Edward F. Andrews, Edward J. Anthony, Gillard W. Apgar, F. A. Armstrong, Thomas F. Attix Electric Engineering Company, W. F. Austin, C. F. Adams, H. C. Alvord, P. R. Atkinson, C. A. Barton, Barrell & Treshen, Bateman & Miller, A. S. Beach, F. Birk, George Bischoff, H. W. Bishop, Frank G. Blanchard, Francis T. Braillard, Brooklyn Electric and Construction Company, A. W. Brown, Brown Brothers, M. S. & P. S. Brown, I. Bugg, William Banta, C. W. Brown, Thomas Boudreau, J. F. Becker, Jr.; E. W. Babcock, G. E. Brown, E. A. Baily, G. E. Bruen, T. Beran, A. D. Bablon, James D. Campbell, Carrano Brothers, Charles H. Clark, Lincoln C. Cocheu, Collier, Smith & Company, Contractors Electrical Company, Thomas H. Cooper, C. Cumberworth, J. J. Carboy, C. W. Copeland, William A. Carey, N. A. Cassidy, J. D. Coveney, Samuel Chase, C. A. Christensen, H. E. Conklin, W. J. Canning, P. De Latinovics, J. C. Donnelly, Jr.; H. G. Disque, S. Davies, Electrical Contracting and Repairing Company, Emergency Electrical Construction Company, J. H. Evans, Henry Fallek, Force & Sheldon, H. Fortenbach, John Fowler, W. W. Freeman, H. F. Fresse, W. T. Fairbairn, Robert Findlay Manufacturing Company (E. J. Greene), J. C. Forsythe, W. Ferris, A. E. Green, F. Gunian, W. P. Graef, C. A. Graves, Theodore R. Guild, J. J. Gohan, Globe Electric Company, Philip J. Hamm, M. J. Hanson, Paul Helfer, Louis Hirtenstein, William Hurth, Leonard J. Huking, Z. M. Hyer, R. A. Haight, W. F. Hutchinson, H. Hochhavsen, Fred C. Hill, R. Holt, J. J. Holshuh, F. E. Hall, Harding & Roth, Joseph Ingram, Interurban Electric and Equipment Company, J. A. Johnson, P. Johnson, Johnson & Sloan, George O. Jenney, Louis Kallisher, L. Karan, Kent Grete Electric Company, A. Kleinfeldt, P. J. Koster, John L. Kruger, Kirshmer, G. L. Knight, James A. Kenney, William Keener, G. M. Kebbe, Justus G. Lang, A. Lang, Levine Electric Company, Isaac Lillenstern, Thomas J. Little, J. J. Leddy, Edward Latham, J. W. Lafferty, Frederick Luckett, James Luckett, R. D. Langley, R. Manquis & Son, Martin Electric Company, John A. Mattefeld, A. J. McNamara, Mezger & Company, Monaton Construction Company, Moncrief & Dean, F. M. Montignani, C. J. Mullin, D. Murphy, Noel A. Myers, Peter D. Myers, H. F. Musgrave, G. M. McMullin, L. E. Moffitt, A. T. Murray, T. C. Martin, A. O. Miller, W. J. Moore, R. M. Mann, Alfred Moore, E. H. Myer, H. C. Mathey, C. C. McIntyre, R. H. Mount, J. E. Muhl, W. C. Meinch, A. Newberger Electric Company, William Nicolay, Frederick Nolte, Nowak & Ward, William Nelson, A. B. Neill, Nicholas Gas Fixture Manufacturing Company, P. O'Rourke, Charles Piesch, Potbury & Wagner, Prospect Electric Construction Company, John Powers, I. D. Phillips, J. H. Porter, C. W. Price, Joseph M. Quigley, A. W. Reamer, Robert Reichard, F. J. V. Rhodes, E. J. Roeder, James Rooney, Charles Rosenberg, Ross Brothers, F. E. Richards, George W. Regan, C. P. Stephan, Staines, Bunn & Taber Company; M. S. Seelman, George Sabel & Son, J. G. Saltsman, N. Samuelson, Schaefer Construction Company, C. Schweitzer & Company, O. E. Seastrand, Leo Skememe & Company, Sleaster-O'Byrne Company, A. Solberg, Charles A. Soper, Frederick Spring, Eugene B. Stratton, J. A. Swin, J. K. Simmonds, E. Schaible, P. D. Sharkey, Edward Sullivan, O. E. Smith, C. W. Simpkins, Thomas J. Spence, F. Slater, M. Tannebaum, E. J. Theimer, E. F. Thomas, C. H. Thurling, C. F. Tuttle, W. D. Van Roden, W. C. Vosburg Manufacturing Company, C. H. Van Der Leith, George J. Wagner, Wall & Klein, Frederick H. Ward, R. J. Ward & Son, George L. Warren, William Watson, George Weiderman Electric Company, A. T. Weigold, Jr.; F. Weitzstein, Chester Wells, H. F. Walcott, Charles J. Woodward, W. J. Walsh, J. E. Wallace, F. E. Wegner, H. H. Wells, J. L. Wiltse, Cecil R. Wood, W. F. Wells, H. P. Wood, C. E. White, Herbert S. Wynkoop, W. C. Ward, Roger Williams.

FINANCIAL REPORTS OF ELECTRICAL COMPANIES.

LAKE SHORE ELECTRIC RAILWAY COMPANY.

The report of the Lake Shore Electric Railway Company, Cleveland, Ohio, for June and the twelve months ended June 30 shows June gross of $78,827; expenses and taxes, $43,644; interest, $25,893; June surplus, $9,920. This compares with $14,134 for the same period last year. Twelve months' gross, $922,914; expenses and taxes, $514,670; interest, $305,785; twelve months' surplus, $102,459; a decrease of $25,907 over the same period last year.

CHICAGO TELEPHONE COMPANY.

The Chicago Telephone Company reports gross revenue for the six months ended June 30 last of $4,188,844, an increase of $7,935; total net revenue of $1,546,880, an increase of $298,315, and surplus after dividends of $540,840, an increase of $55,596. The report says:

"The new ordinance rates went into effect December 1 last. It is not possible to make an exact comparison between operations for 1907 and 1908, with reference to the effect of the new ordinance which lowered rates materially, for the reason that operations of the company in the city and outside of the city were not kept separately for 1907. A rough approximation of the effect of the new ordinance rates is that receipts of the telephone company from 210,000 telephones (city and country) is the same as for 180,000 telephones at old rate, a money difference of about $1,400,000 per annum. At the same time the average capital account is increased $3,340,000 in part payment for 31,000 additional telephone stations. Operating conditions have been more favorable in 1908 than last year in that the heavy repairs required because of frequent storms were less, so that operating expenses were less."

The American Street and Interurban Railway Association Convention.

The annual convention of the American Street and Interurban Railway Association and the affiliated associations of the Engineers, Claim Agents, Accountants, Transportation and Traffic Association and the Manufacturers' Association, will be held at Atlantic City, N. J., from October 12 to October 16.

Young's million-dollar pier has been selected as the exhibit place, and a majority of the convention meetings will also be held on the pier. Over 60,000 square feet of space for exhibit purposes is available, and the indications point to an exhibit which will be fully as large and as interesting as that given in 1907.

The committees on subjects for the various associations have been actively engaged on programmes for several months, and interesting papers will be presented at the sessions of each association.

The morning of Monday, October 12, will be reserved for registration purposes and the first meetings of the convention will be held on the afternoon of that day. The meetings will continue throughout the week, closing on Friday, October 16. The following general schedule of meeting days has been decided upon:

MONDAY, OCTOBER 12.

9.30 A. M.—12.30 P. M.—Registration and Badges—Claim Agents' Association; Transportation and Traffic Association.

2.00 P. M.—5.00 P. M.—Meeting of Claim Agents' Association; Meeting of Transportation and Traffic Association.

TUESDAY, OCTOBER 13.

9.30 A. M.—12.30 P. M.—Registration and Badges—American Association; Engineering Association; Meeting of Claim Agents' Association; Meeting of Transportation and Traffic Association.

2.00 P. M.—5.00 P. M.—Registration and Badges—Accountants' Association; Meeting of American Association; Meeting of Engineering Association; Meeting of Claim Agents' Association.

WEDNESDAY, OCTOBER 14.

9.30 A. M.—12.30 P. M.—Meeting of Accountants' Association; Meeting of Engineering Association; Meeting of Claim Agents' Association; Meeting of Transportation and Traffic Association.

2.00 P. M.—5.00 P. M.—Meeting of American Association; Meeting of Engineering Association.

THURSDAY, OCTOBER 15.

9.30 A. M.—12.30 P. M.—Meeting of Accountants' Association; Meeting of Transportation and Traffic Association; Inspection of Exhibits by Engineering Association.

2.00 P. M.—5.00 P. M.—Meeting of American Association; Inspection of Exhibits by Engineering Association.

FRIDAY, OCTOBER 16.

9.30 A. M.—12.30 P. M.—Meeting of Accountants' Association; Meeting of Engineering Association.

2.00 P. M.—5.00 P. M.—Meeting of Engineering Association.

In addition to the above programme the Accountants' Association will have a "Get Together" lunch and smoker on Wednesday afternoon; the Claim Agents will have a smoker on Tuesday evening and the Transportation and Traffic Association will have a dinner on Wednesday evening. Similar arrangements will probably be made for the American and Engineering associations.

Two convention halls, located on the convention pier and each capable of seating approximately 300 people, will be provided for the meetings of the convention. In addition, suitable meeting rooms are available in the Chalfonte Hotel and in the Traymore Hotel.

All of the meetings of the American Association, the Engineering Association and the Transportation and Traffic Association will be held in the meeting halls on the convention pier. The accountants will hold their two sessions on Wednesday at the Chalfonte Hotel, and their Thursday and Friday sessions on the convention pier. The claim agents will hold all of their sessions at the Traymore Hotel.

Advanced Degrees in Electrical Engineering, Including the Degree of Doctor of Engineering, at the Massachusetts Institute of Technology.

The demand for young men with a more extended and a deeper training in electrical engineering theory than can be obtained in an undergraduate engineering course has led the Massachusetts Institute of Technology to emphasize its graduate courses. These graduate courses lead either to the degree of Master of Science, for young men who propose to spend one year in advanced study of electrical engineering, or to the degree of Doctor of Philosophy or Doctor of Engineering, for young men who propose to spend longer periods in their advanced study and research. The degrees of Master of Science and Doctor of Engineering are particularly applicable to students following electrical engineering studies, and lectures, seminars, and other advanced instruction for students who are candidates for the doctor's degree will be well under way in the electrical engineering department during the next school year. In addition to students who will follow the course leading to the degree of Master of Science, candidates who will follow the work leading to the degree of Doctor of Engineering have already arranged to begin this work next fall at the institute. The advanced work leading to the doctor's degree may follow in its major part either the lines outlined by Professor Jackson's lectures on the organization and administration of public service companies, or by Professor Clifford's advanced course on alternating currents, as the individual student may choose, and it is expected to be accompanied by such other work as may be chosen by the individual student (subject to faculty approval) from other departments of science and engineering. It is believed by the faculty of the Massachusetts Institute of Technology that engineering students of particular ability can well afford to spend from one to three years of special advanced study under competent instructors along the lines of engineering theory and practice, and that such students will profit largely from the results of such study. Indeed, this seems to be proved by the experience of numbers of engineering students who have gone through courses of advanced study in engineering or scientific schools either in this country or abroad. The schools of foreign countries were doubtless formerly in advance of the American schools, for the purpose of advanced study in engineering and applied science, but it is believed that this condition no longer prevails. The advanced courses in electrical engineering at the Massachusetts Institute of Technology are planned particularly with a view to meeting the needs of such students as have hitherto found it necessary to go to foreign countries for advanced engineering instruction.

Electrical Supplies for the Navy Department.

The Bureau of Supplies and Accounts, Washington, D. C., will open bids on September 8 for the following electrical material: Six primary condensers, miscellaneous insulators, 600 Leyden jars, 250 condenser plates, 20,000 feet phosphor-bronze wire, for delivery at Mare Island, Cal.

Coal-Mining Reports.

Indiana continues to rank sixth among the coal-producing states of the Union, and in 1907 it was a close rival of Alabama for fifth place.

The total coal production of the state in 1907 was 13,985,713 short tons, having a spot value of $15,114,300, an increase over the production of the preceding year of 1,893,153 short tons, or 15.66 per cent, in quantity, and of $1,998,039, or 15.23 per cent, in value. The growth of the industry in the last three decades, as shown by the statistics published by the United States Geological Survey, has been remarkable. The production of coal in the state in 1870, reported by the census for that year, was 437,870 short tons; in 1880 it was 1,454,327 tons; in 1890 it amounted to 3,305,737 tons. In the closing year of the last century the production had nearly doubled again, amounting to 6,484,086 short tons, and this output was once more nearly doubled by the tonnage of 1907.

The output of coal in Kentucky in 1907—10,753,124 short tons, having a spot value of $11,405,038—was the largest in the history of the state, being nearly three times that of 1897 and nearly double that of 1901.

In a preliminary statement given to the press by the United States Geological Survey early in February it was estimated that the coal production of Kentucky for 1907 had increased about 10 per cent over that of 1906. The complete statistics for the state, as reported to the Survey, show a gain in production of 1,099,177 short tons, or 11.39 per cent, in quantity, and $1,595,100, or 16.26 per cent, in value. The increase would probably have been considerably greater, in spite of the financial flurry marking the closing months of the year, had not the abnormally high temperatures that prevailed during November and December lessened the usual demand for coal for local consumption.

The total production of coal in North Dakota in 1907 was 347,760 short tons, having a spot value of $560,199—a gain over the output in the preceding year of 42,071 short tons, or 13.76 per cent, in quantity, and of $108,617, or 24.11 per cent, in value.

The lignite mines of the state gave employment in 1907 to 562 men, who worked for an average of 223 days, as compared with 488 men, who worked for an average of 209 days, in 1906. The average production per man decreased from 626.4 tons in 1906 to 619 tons in 1907, while the daily production for each employé decreased from three tons in 1906 to 2.78 tons in 1907. The number of mining machines in use increased from nine in 1905 to eleven in 1906 and to twelve in 1907, while the machine-mined product, which decreased from 97,789 tons in 1905 to 97,035 tons in 1906, increased to 136,700 tons in 1907.

Oppose Funding Plan.

Dissatisfaction among the bondholders of the Hudson River Electric Power Company over the plan announced by the company recently providing for funding of the coupons for a period of four years, has resulted in the formation of a committee to protect the interests of the bondholders. The offer of the company to give, in exchange for the coupons, five per cent notes secured by the coupons themselves, in addition to a ten per cent stock bonus, is not liked by many of the bondholders.

Recently Eugene L. Ashley, president of the company, in a circular to stockholders requesting them to consent to the funding scheme, stated that there had been a substantial increase in gross and net earnings of the several controlled companies, until the last quarter of last year, when the falling off then made it impossible for the company to meet its interest charges. In addition to the decline in earnings, he said, the company had a floating debt of $600,000, which it had been unable to retire by the sale of bonds. At that time a large majority of the bondholders assented to the plan, according to President Ashley.

Now some of the bondholders contend that they are not satisfied concerning the necessity of defaulting the August 1 interest payments, and substitute this plan of funding cash. They state their intention of taking steps to secure an independent audit of the company's books to determine just what the financial status of the company is, and also the relation of the parent company's finances to those of its subsidiary companies, the Hudson River Water Power Company, the Hudson River Electric Company, the Hudson River Power Transmission Company, and others.

To further these steps the following committee has been formed: John A. Young, president of the Windsor Trust Company, of New York; James C. Chaplin, vice-president of the Colonial Trust Company, of Pittsburg; Harlan W. Whipple, president of the Central Trust and Savings Company, of Philadelphia; Le Roy W. Baldwin, president of the Empire Trust Company, of New York. Parker, Hatch & Sheehan and Rollins & Rollins, of New York, and J. H. McNeal, of Philadelphia, are counsel for the committee. Winthrop E. Scarritt, of New York, is secretary.

Public Service Commission Ruling on Isolated Plants.

Chairman Stevens, of the Public Service Commission in the Second District, state of New York, announced at Albany on August 5 that the commission holds that under the definition of an electrical corporation as laid down in the Public Service Commissions law, persons may be considered as electrical corporations. This is the first public announcement of the commission in regard to its position as to its jurisdiction over individuals operating lighting plants.

The announcement was made after the hearing in the case of Albert H. and Lynn B. Murdock, of Oneonta, who appeared on an order to show cause why the commission should not begin suit against them for an alleged violation of the Public Service Commissions law in operating an electrical lighting plant and occupying public streets and places in the village of Oneonta. The order was made on the complaint of the Oneonta Light and Power Company, which now furnishes light to the village.

The Murdocks asserted that they were not an electrical corporation, and therefore not subject to the jurisdiction of the commission. They, however, said they did not intend to proceed further in furnishing light or occupying streets in Oneonta, and the matter was dismissed.

Power Companies Merge.

Announcement has been made at Raleigh, N. C., of the merger of the Raleigh Electric Company, of Raleigh; the Central Carolina Power Company, of Buckhorn Falls, and the Consumers' Light and Power Company, of Sanford, the new concern being known as the Carolina Power and Lighting Company. It controls the street car and lighting system of Raleigh, the power systems of Raleigh, Fayetteville and Sanford. These companies are all financed by the Electric Bond and Share Company, of New York. From the power plant at Buckhorn Falls power is now transmitted to Fayetteville and this will be brought to Raleigh and Sanford.

Wireless for Alaska.

A wireless station in Prince William Sound, Alaska, is to be erected by the Navy Department, the exact site to be selected shortly. This will be about 500 miles from the military wireless station being installed in Fort Gibbon, and will form a connecting link between that station and the naval wireless station at North Head, Wash. The government then will be able to maintain wireless communication up the Pacific coast to the Alaska station, which forms a part of the Alaska military wireless telegraph system.

The Brusio Hydroelectric Plant and Its 50,000-Volt Swiss-Italian Transmission System.—II.

(Concluded.)

By Frank Koester.

CURRENT DISTRIBUTION.

As previously stated, much of the current generated must be transmitted across the boundary line into Italy, and it was deemed advisable to run duplicate circuits to the substation at Piattamala. Since, however, the valley is quite narrow and atmospheric discharges are of great frequency, a tunnel was built for the purpose of carrying these wires to this station.

The conductors leave the basement of the switchroom and cross the River Poschiavino through a covered bridge (see Fig. 3[1]), where they then enter the tunnel mentioned. This tunnel, which runs to the substation, is 1,650 feet long. It is 8.2 feet wide and 9.8 feet high, the top being arched.

Owing to the customs regulations between the two countries, the tunnel can not be entered from the power-house end. Entrance is obtained, however, through a door visible from the street, while at the boundary line the tunnel is closed off by an iron door separating the Italian and Swiss sections. The accompanying cross-section, Fig. 10, illustrates the scheme of arranging the conductors in the tunnel. These conductors consist of copper bars, 0.25 square inch in section, which are carried on petticoat insulators supported on channel irons projecting from the side walls of the tunnel. These channels are spaced longitudinally 4.9 feet, with reinforced concrete slabs spanning them and forming partitions between the conductors. The outgoing feeders tap the middle of the bus-bar system, then are carried on either side of the tunnel to the substation. For the protection of the customs officials the conductors are provided with a removable wire netting.

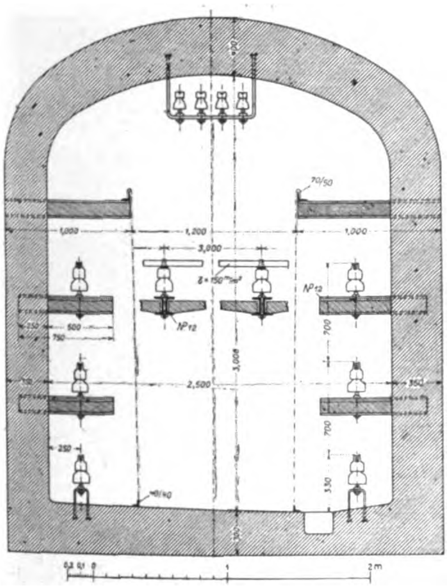

Fig. 10.—Cross-Section of Cable Tunnel Leading Across Boundary, Between Power-House and Step-Up Transformer Station, Brusio Hydroelectric Plant.

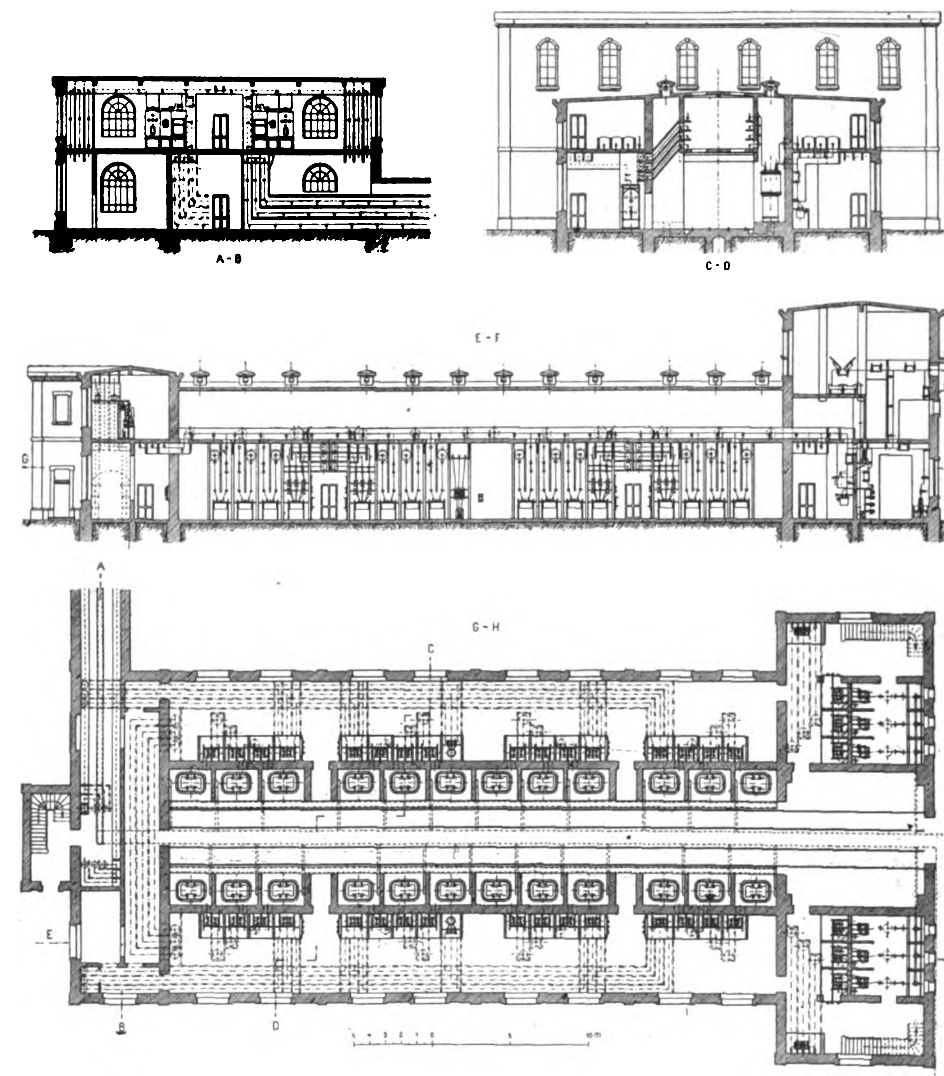

Fig. 11.—Plan and Elevation, Step-Up Transformer Station at Piattamala.

STEP-UP STATION, PIATTAMALA.

As will be seen from the accompanying plan, this station is built in the shape of a T, 180.5 feet long, 68.8 feet wide and 28.2 feet high, the cross-arm being ninety-two feet long by 42.6 feet high. It is designed to accommodate twenty-four single-phase transformers having a capacity of 1,250 kilowatts each. At present there are thirteen installed, with a total normal capacity of 16,250 kilowatts.

At one end of the transformer room is the meter room, where the current is checked by the two companies. The transformers are arranged in two rows, between which are two tracks leading into the inspection and repair room. This is in the middle of the cross-arm of the T, in which there is a ten-ton traveling crane. The transformer-switchboard rooms are directly behind each row of transformers. From the illustration it will be seen that the substation is divided into two distinct sections. The outgoing feeders leave the building from the third story of the cross-wing.

The feeder lines from the power station enter the substation from the tunnel on the ground floor, as the station (Fig. 12) is built into the hillside. As two companies are concerned in the amount of current used, the Brusio company supply-

[1] Electrical Review, August 8.

ing the power and the Societa Lombarda receiving the current for distribution, this room, on the second floor, is thoroughly equipped with measuring instruments, some of which are kilowatt meters of different makes, and are switched in series in order to check each other.

The meter switches are so arranged that the current may be thrown onto either row of transformers from either of the two feeder lines, or the current from both feeders may be thrown on one row of transformers only. The oil switches in the meter room are of the remote-control, hand-operated type. It was not deemed advisable to install automatic switches, because a sudden cutting out the whole load, which might amount to 20,000 kilowatts, might seriously interfere with the operation of the plant, particularly the hydraulic end.

Above the aisle, between the two rows of transformers, and extending the full length of the room, is a mezzanine floor carrying the feeders in two vertical rows, one on either side, to the transformers. The phases of the bus-bar system are separated by concrete shelves, the front remaining open. The high-tension, or 50,000-volt, bus-bars run on the mezzanine floor above the transformer switchboard or operating rooms. These bus-bars are arranged in horizontal rows separated by concrete partitions but not covered.

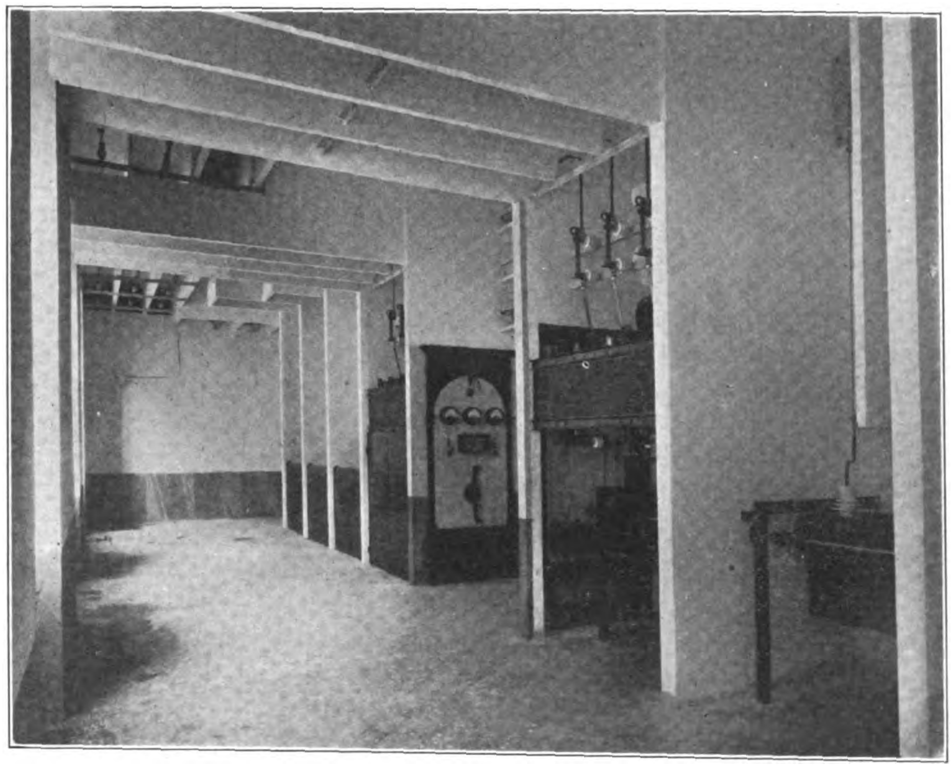

FIG. 13.—SWITCH ROOM AT THE STEP-UP TRANSFORMER STATION AT PIATTAMALA.

The transformers are of the Alioth water-cooled oil type, a system of water circulation from a spring under a head of twenty-six feet being provided. The efficiency of the transformers under actual test at full load was 97.5 per cent; at half load, 96.5 per cent. The drop in voltage between no load and full load with a power-factor, cos $\phi = 1$ is one per cent. With cos $\phi = 0.8$ is 2.2 per cent. The greatest drop is 2.8 per cent.

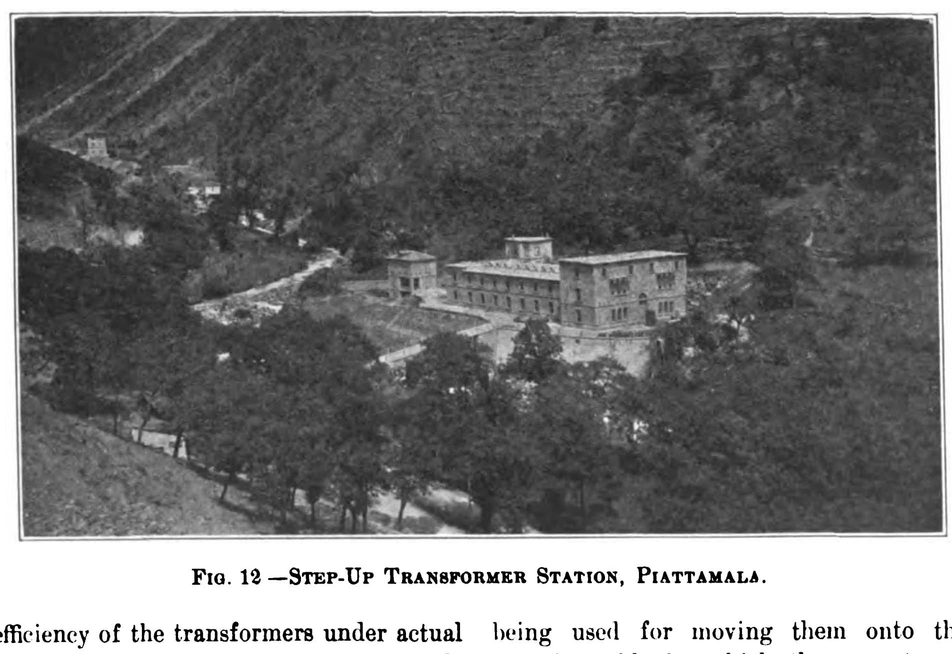

FIG. 12.—STEP-UP TRANSFORMER STATION, PIATTAMALA.

Each transformer is contained in a well-ventilated concrete compartment, the front being provided with a corrugated-iron rolling shutter. The transformers are provided with pinion wheels resting on pairs of racks secured to the floor, the transfer table also being provided with such racks. This device greatly facilitates the handling of the transformers, a ratchet being used for moving them onto the transfer table by which they are transported on the track to the inspection and repair room, where the cores are easily taken out by the overhead crane.

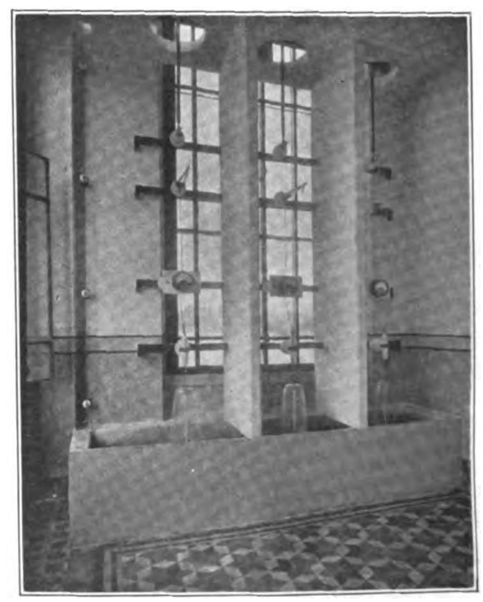

FIG. 14.—FIFTY-THOUSAND-VOLT WATER-FLOW LIGHTNING ARRESTERS AT STEP-UP STATION, PIATTAMALA.

Each transformer is provided on the low-tension side (7,000-volt) with a three-pole oil switch, while on the high-tension side (50,000-volt) three oil switches, one for each phase, are provided. These switches, interconnected, are remote-controlled, and may be operated either by hand or automatically. Access to the 7,000-volt switches, which are protected by doors, can only be had when the current is off. The 50,000-volt switches are similarly protected. All these switches are accessible from the aisles of the operating rooms. Between each group of transformers sectionalizing switches and choke-coils are provided for protection against variations in load caused by throwing the switches.

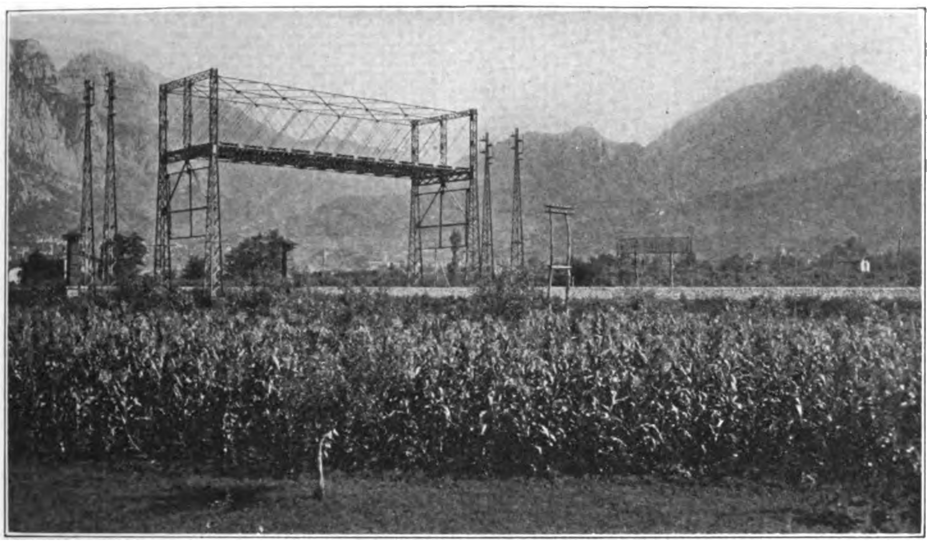

FIG. 15.—RAILWAY CROSSING.

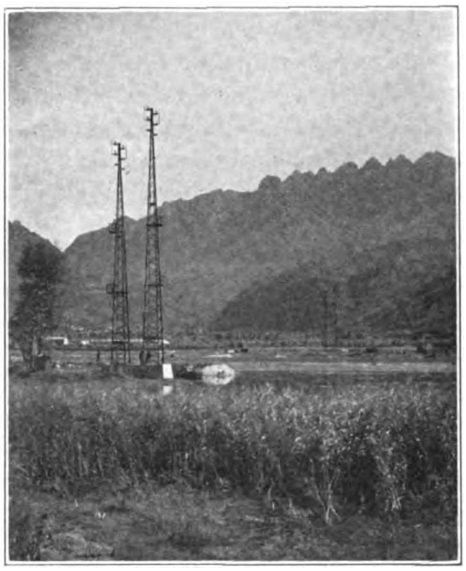

FIG. 16.—SPAN OVER RIVER ADDA BELOW LECCO.

On account of the high tension and long transmission line, the great variation in altitude and consequent difference in temperatures, and particularly on account of the frequent storms and atmospheric discharges, various devices were installed for protection against surges. For this purpose the choke-coils above mentioned are placed on each side of the transformers, and horn lightning arresters are placed on the outgoing feeders. The latter have a gap of two and three-eighths inches and are connected in series with water-flow resistances. The choke-coils consist of two spools, having a brass core, upon which is tightly wound a copper band of sixty turns, separated by insulating material, thus forming a solid tightly wound spool which sudden surges will not distort. For taking up lighter static and atmospheric discharges, the more sensitive roll lightning arresters were installed and connected in series with water-flow resistances. Finally, as all surges will create more or less variation in pressure, water-flow rheostats are installed for each phase to maintain a uniform pressure. This apparatus consists of a nozzle for forcing a jet of water, under a head of twenty-six feet (supplied from above-mentioned spring), against a baffle-plate connected to the line. The stream of water is three-eighths inch diameter and twenty-eight inches high and allows a leakage of one-tenth ampere. Ammeters are inserted in the wire connection to this apparatus in order to detect failures in the grounding. All lightning arresters, as well as the outgoing lines, are provided with disconnecting switches. All metallic features of the installation are interconnected and well grounded. Figs. 13 and 14 show switch-room and water-flow rheostats at Piattamala.

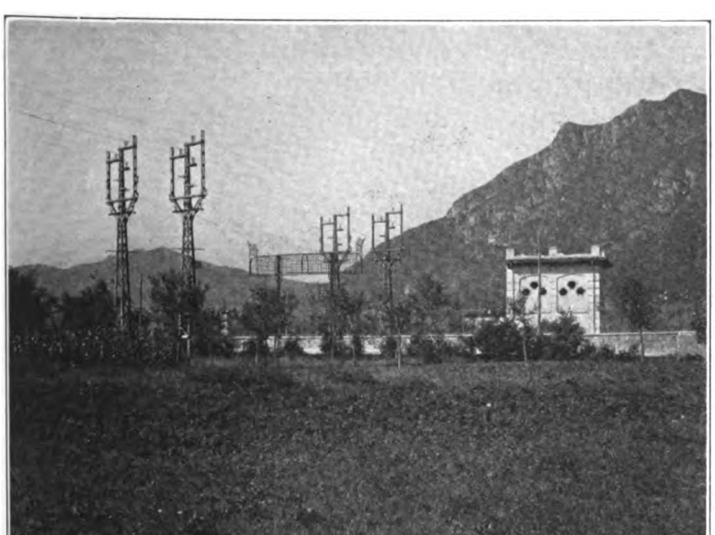

FIG. 17.—STREET AND TELEPHONE CROSSING NEAR LECCO; ALSO SECTION SWITCH HOUSE.

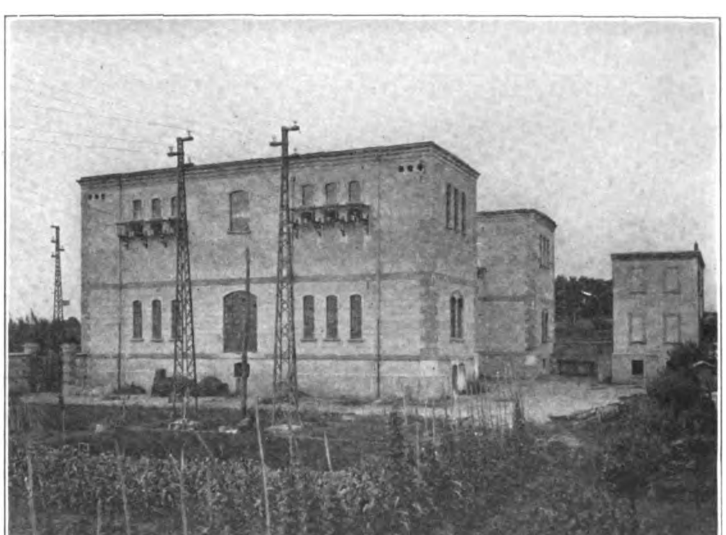

FIG. 18.—STEP-DOWN TRANSFORMER STATION AT LOMAZZO.

TRANSMISSION LINES.

The transmission line (50,000-volt) may be considered the most important in Europe. It consists of two independent lines, each 88.5 miles long. As the line runs over mountains and valleys, the peaks were avoided as much as possible to escape the unavoidable difficulties due to atmospheric discharges. These lines cross three provinces and ninety-four townships, and required the right of way through 6,000 properties, the cost of which averaged about $800 per mile. The lines cross ten railways, one tramway, ten state roads and 120 county roads.

From the main substation at Piattamala the line runs westward through the

Adda Valley to Colico, thence along the shore of Lake Como to Bellano, from which point it runs in a southeasterly direction over the Valsasina Plateau. Palasco, the highest point of the line, is 2,130 feet above sea level. From Valsasina the lines run in the mountains of Lecco in a southwesterly direction and cross the Adda Valley with a span of 720 feet, this being the lowest point of the line (640 feet above sea level). From here until the first step-down station, at Lomazzo, is reached, 84.5 miles distant from the step-up station at Piattamala, the run is practically straight. Eight and one-half miles beyond Lomazzo, at Castellanza, is another step-down station.

The average span is 393 feet. In eighty-seven cases, however, the span exceeded the average, the longest span being 1,280 feet, across the Gravina Valley at Colico. The transmission line consists of two parallel rows of towers, from thirteen to 16.5 feet apart, of latticed-girder construction imbedded in concrete. Each tower is provided with six brackets, three for present use and three for future extension, so that there will be eventually four separate three-phase circuits. The porcelain insulators are supported on pins, fastened to oak and chestnut blocks secured to the steel brackets. Each cable consists of nineteen wires, 2.6 millimetres in diameter, the total diameter of the cable being fourteen millimetres (105 square millimetres area).

The towers are calculated for a wind pressure of seventy miles per hour, allowing a stress in the copper of 8,500 pounds per square inch and on the tower of 17,000 pounds per square inch. Allowance is made for a temperature difference of 120 degrees Fahrenheit. On account of the difference in the spans and frequent changes in direction of the lines, four different types of towers are employed, weighing from 1,250 to 2,500 pounds each. There are a total of 3,100 towers, averag-

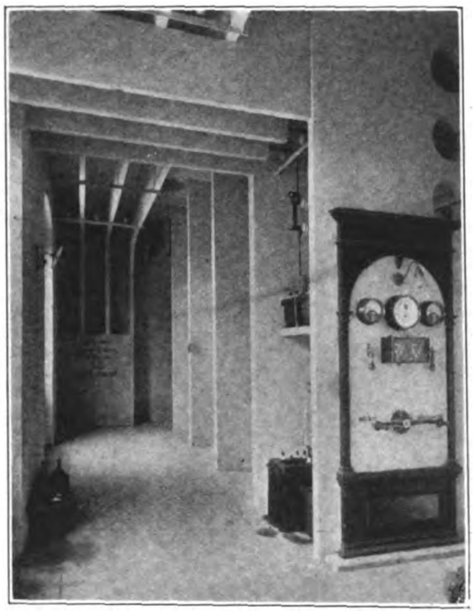

Fig. 19.—Fifty-Thousand-Volt Switch Room at Lomazzo.

ing in price $80 each, including foundation and erection. The two existing lines represent 900 gross tons of copper and 10,000 insulators at $2.60 each, including mounting and wooden blocks. The laying of the cables cost $128 per mile of transmission.

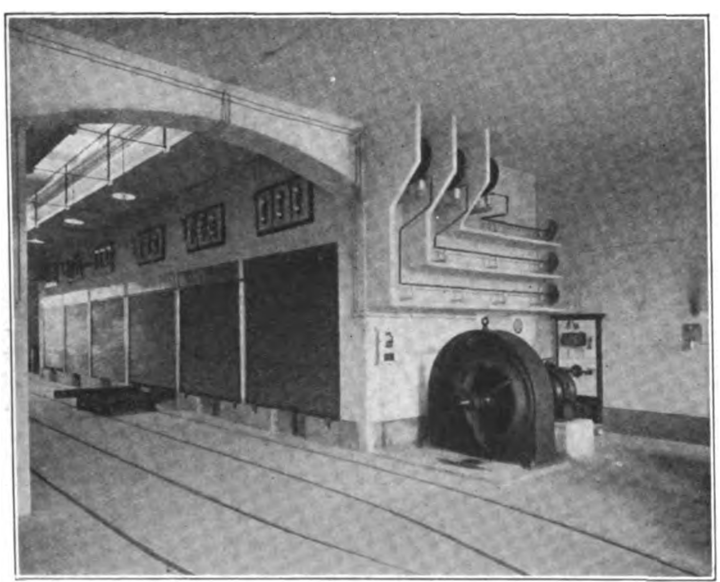

Fig. 20.—Transformer Room at Lomazzo.

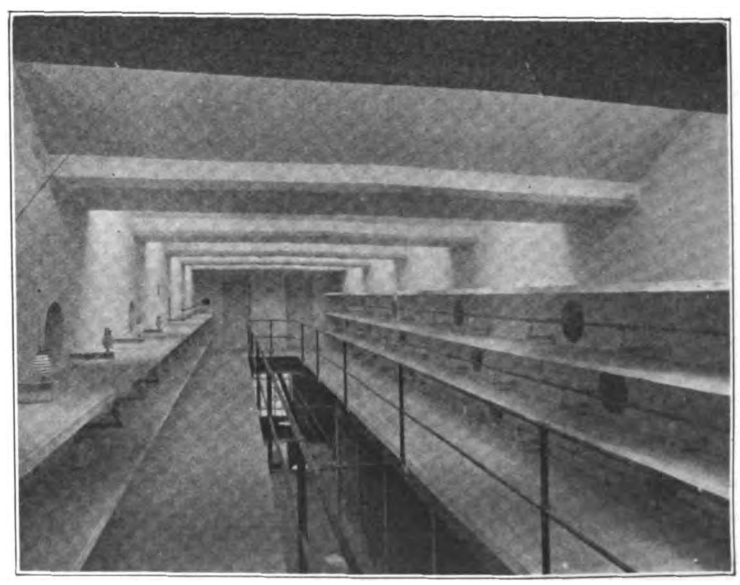

Fig. 21.—Bus-Bar Arrangement at Lomazzo.

The transmission system is divided into six sections, varying from 8.5 to 25.5 miles, and is provided with section switches, arranged so that in case of a break in a section of one line the current may be by-passed over the other line. There is a small station at each section for housing the sectionalizing switches, measuring apparatus, lightning arresters, some of which are of the horn type, some of the coil type and some are also provided with water-flow rheostats as described previously.

At a distance of sixty-five feet and parallel with the high-tension lines, a telephone and telegraph line is carried the entire length of the transmission system for the exclusive use of the plant. There are two wires carried on wooden poles and thirty stations costing $30 each, while the line costs about $380 per mile. Fig. 15 shows the transmission line crossing the railway. Fig. 16 shows the long span over the River Adda. Fig. 17 shows the transmission line crossing the street and the telephone wires, and also a section switch house near Lecco.

TRANSFORMER STATION, LOMAZZO.

This substation is located centrally in the low-tension distributing district. It is built in the form of an I. The wing at one end containing the apparatus for the incoming feeders is eighty-five feet by thirty feet, and forty-eight feet high. The wing at the opposite end is of the same dimensions and contains the apparatus for the outgoing feeders. The middle member of the building, containing the transformers, is fifty-five feet wide by sixty feet long and thirty-three feet high. The over-all dimensions are eighty-five feet by 120 feet.

The two 50,000-volt circuits enter the second floor of one of the wings in a way similar to the outgoing feeders leaving the step-up station at Piattamala. The feeders are similarly protected against electrical discharges, excepting that the water-flow lightning arresters are supplied with water by a centrifugal pump and tank under a head of forty feet instead of a natural head from the mountain stream. The transformers (1,250 kilowatts, 50,000-11,000 volts) are arranged in two rows, similar to those at Piattamala, with tracks in front of the compartments, of which there are six on each side. There are also six three-phase transformers of 5,000 kilowatts each (11,000-20,000 volts). There are at present installed only three single-phase and three three-phase transformers. While the transformers at Piattamala are of the oil-cooled, water-circulating type, those at this station (Lomazzo) are of the forced-air-cooled type, for which two blowers are at present installed. The final equipment demands four blowers, of which two will be kept in reserve. The blowers are motor-driven and discharge through air ducts located beneath the two rows of transformers. The cores of the transformers are not encased. The fronts of the transformer compartments are provided with rolling shutters, and ventilators are placed in the roof. Good results were obtained with these transformers, an advantage being that the cores can be easily inspected. The primary winding is provided with taps so that the voltage may be reduced to 35,000. This was done so that easy regulation might be secured. The tests show that the efficiency at full load is ninety-seven per cent and at half load 96.5 per cent. The pressure loss at full load with a power-factor of cos $\phi = 1$ is one per cent, and with a power-factor 0.8 it is three per cent. The temperature rise is forty degrees centigrade. The high and low-tension sides, respectively, were tested to 65,000 and 17,000 volts, ten minutes' duration. The transformers are capable of standing an overload of twenty-five per cent with a total temperature rise of sixty degrees centigrade. The operation of the blowers is included in the above-named efficiencies.

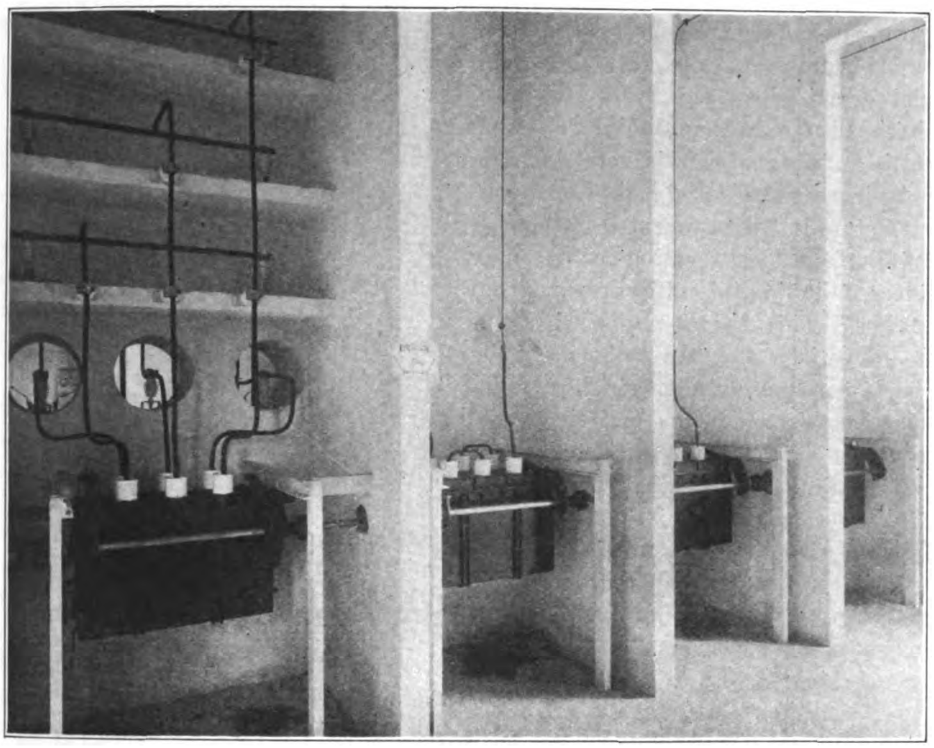

Fig. 23.—Switch Group, 11,000-20,000 Volts, at Lomazzo.

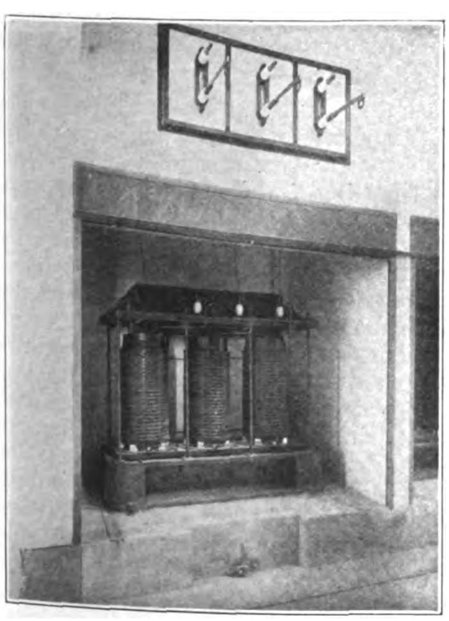

Fig. 22.—Five-Thousand-Kilovolt-Ampere, Open-Type, Air-Cooled Transformer at Lomazzo.

The 11,000-20,000-volt, 500-kilowatt, three-phase transformers have an efficiency of ninety-seven per cent at full load with a power-factor of cos $\phi = 1$, while with cos $\phi = 0.8$ is ninety-six per cent and three-quarters load ninety-six per cent and ninety-five per cent, while at half load it is 95.5 and 94.5 per cent. The drop in pressure is 1.5 per cent with a power-factor of cos $\phi = 1$, and three per cent with a power-factor of 0.8. The temperature rise is fifty degrees centigrade and the overload capacity is twenty per cent for two hours.

The wiring diagram is made so that under normal operating condition the line "A" will distribute 11,000-volt current in the district about Lomazzo, and "B" and "C" will supply Castellanza. The arrangement is such that one bus-bar system may feed either of the outgoing lines, or that the line "A" to Lomazzo may be fed from line "C." Through the line "C" 11,000-volt current may be drawn from the steam-power plant at Castellanza, of the Società Lombarda, which is a reserve for the hydraulic plants at Turbigo and Vizzola. It will be seen that with this auxiliary source of supply, in case of emergency current may be sent through this station (Lomazzo) and through the station at Piattamala to the hydraulic plant at Brusio.

A fourth line of 20,000 volts leads northward to Como, for which purpose the three-phase 11,000-20,000-volt transformers were installed.

The feeders from the 50,000-11,000-volt transformers lead to the three-pole oil switches on the mezzanine floor above the aisle between the two rows of transformers. The feeders to and from the transformers are provided with cut-out switches.

The 50,000, 11,000 and 20,000-volt bus-bars are arranged, according to the space available, in horizontal or vertical rows, and the phases are separated by concrete shelves or partitions. Three bus-bar compartments remain uncovered. The 20,000-volt outgoing feeders are protected like those at the step-up station at Piattamala. Fig. 18 shows the step-down transformer station at Lomazzo, Fig. 19 shows the 50,000-volt switchroom, Fig. 20 shows the transformer room. Fig. 21 shows the bus-bar arrangement, Fig. 22 shows the 5,000-kilowatt-ampere air-cooled transformers, and Fig. 23 shows the 11,000-20,000-volt switch group.

TRANSFORMER STATION, CASTELLANZA.

As previously stated, the Società Lombarda possesses a steam-power plant at Castellanza having an equipment of two 2,500-horse-power engines and two 5,000-horse-power steam turbines, which work in parallel with the above-described hydroelectric plants at Brusio, Turbigo and Vizzola. A temporary transformer station has been erected in the engine room of this power-house containing six single-phase, 1,250-kilowatt transformers arranged in groups of three. The whole apparatus, owing to the small space available, has been located on three floors. The transformers, which are of the oil, water-cooled type, are designed similarly to those at Piattamala, except for a voltage of 11,000-40,000. Taps are provided so that some coils may be cut out to secure a voltage of 35,000. The efficiency of the transformers at full load is ninety-eight per cent and at half load ninety-seven per cent. The drop in pressure at full load and with a power-factor of cos. $\phi = 1$ is one per cent, while with cos. $\phi = 0.8$ it is two per cent. The rise in temperature is forty-five degrees centigrade, using five gallons of water in twenty minutes at fifteen degrees centigrade. They are capable of standing an overload of twenty-five per cent, maintaining the temperature of forty-five degrees centigrade, and using ten gallons of water, or with a rise of temperature of sixty degrees using five gallons of water. The transformers were tested at 65,000 volts for a duration of ten minutes.

Okonite insulation has been used throughout this station.

As the capacity of the steam-power plant is expected to be increased in the near future, an isolated transformer station is now being erected alongside of this power-house which will accommodate eighteen transformers.

The entire installation was put in operation within two and one-half years from the organization of the company, and is giving most satisfactory results; the expectation being that the maximum output will be reached during this year.

The entire plant was installed in accordance with the plans of the "Electricitäts Gesellschaft Alioth, A. G.," Münchenstein, Switzerland, which also furnished the bulk of the electrical equipment.

BOOK REVIEWS.

"Railway Signaling." By a Staff of Expert Signal Engineers, Pittsburg. The Electric Journal. Cloth. 108 pages. Illustrated. 6½ by 9½ inches. Furnished by the Electrical Review for seventy-five cents.

In this book have been brought together various authoritative articles on signals and signaling which have appeared from time to time in the *Electric Journal*. The subjects dealt with include mechanical interlocking, electro-pneumatic interlocking, electric interlocking, the electric train staff system, automatic block system, both direct and alternating currents, and the language of fixed signals. In each case the principle of the system is clearly explained and the apparatus by which it is put into service is described.

"High-Speed Dynamoelectric Machinery." H. M. Hobart and A. G. Ellis. New York. John Wiley & Sons. Cloth. 526 pages. 355 figures. 6 by 9½ inches. Furnished by the Electrical Review for $6.

The authors of this book have performed a very acceptable task in bringing together and discussing the available information concerning one of the most recent developments in the construction of dynamoelectric machinery—the designing and building of high-speed machines suitable for steam-turbine driving. As is pointed out, the previous developments in this field have been very rapid, important innovations having been made within the last few months. A good deal of the material contained in this book has been published before in the technical journals, but there is much that is new, and the whole is arranged in a logical manner. One feature in the treatment is the giving of first place to alternating-current machinery, following this with direct-current dynamos. This has been done for the sake of variety, and, the authors say, in order to depart from a meaningless tradition. In this we do not entirely agree, because the best arrangement of a course in a technical school is that which takes up direct-current machines first; and, moreover, it must be admitted that, neglecting a few early alternators which had little effect upon subsequent design, the first development was in direct-current machinery; and when alternating-current machinery began to be used, the designers depended largely upon their experience with the other type. Possibly, however, this arrangement may be the most satisfactory for the advanced designer. In the introduction it is pointed out that, in spite of the general opinion that the higher the speed the more satisfactory the machine, this does not apply to continuous-current dynamos; and the two following principles are laid down: "When not carried to excess, the lower the speed in revolutions per minute, the more satisfactory will be the results which may be obtained in designing continuous-current dynamoelectric machines." On the other hand, "When not carried to excess, the higher the speed in revolutions per minute, the more satisfactory will be the results which may be obtained in designing alternating-current dynamoelectric machines." From these two follows a third: "For a given rated output the preferable speed will be much lower for a continuous-current design than for an alternating-current design. The book is divided into three parts. Part i, entitled, "General Instructions," contains four chapters taking up matters common to both classes of machinery. Part ii is devoted to alternating-current generators, and Part iii to continuous-current generators. The treatment throughout is practical, the statements being made clear by numerous examples and a free use of curve sheets, which show how the various quantities change under different conditions. Frequent illustrations of actual machines show how the principles have been put into actual practice.

"Wireless Telephony in Theory and Practice." Ernst Ruhmer. Translated by James Erskine-Murray, with appendix by translator. New York. D. Van Nostrand Company. Cloth. 224 pages. Illustrated. 6 by 9 inches. Furnished by the Electrical Review for $3.50.

The appearance of this work is timely, both on account of the present interest in the new method of space telephony and the uncertainty of many engineers as to the precise difference in the *modus operandi* of space telegraphy and telephony. The book divides the subject into two main parts, the first being "Radiophony, or Wireless Telephony by means of Light or Heat Radiation." The second is "Wireless Telephony Proper, or Telephony by Means of Electromagnetic Forces." The first part contains six chapters dealing with the various schemes devised for telephoning without wires, not, of course, including those coming under the second division. In the second part of the book there are thirteen chapters, treating of closed-circuit telephony, electromagnetic induction telephony, spark telephony, accelerated spark rates, multiphase spark discharges, high-frequency alternators, the arc as a high-frequency generator, the Poulsen generator, multiple arcs in air, the application of the arc to telephony, the Duddell phenomenon, forced vibrations, and then a general conclusion. There is an appendix by the translator, referring to recent monographs on high-frequency work, with an account of Fessenden's experiments at Brant Rock. There is also a fairly comprehensive bibliography and two good indices of names and subjects. The book as a whole is logically arranged, though certain chapter divisions are somewhat artificial. The work of various investigators is painstakingly if, at times, arbitrarily, followed up, the result being a popular, instead of a scientific, account. No consistent mathematical treatment is given, except a perfunctory statement of the general charging equation of a resonant circuit which shows nothing not equally well given by the diagrams. In spite of this the book is the best to date on its subject, in English. One criticism may be made of the appendix. In this Dr. Murray refers to Dr. Barkhausen's recent monographs on force oscillations, but makes no reference to Wien's classical paper on "The Reaction of a Resonating System." Nor is this referred to even in the preface. At times throughout the book the personal equation becomes painfully evident, much space being given to the author's own work, and the parallel work of others being dismissed with a casual reference.

SOME CONSIDERATIONS ON THE DESIGN OF A GENERATING STATION.[1]

BY H. RICHARDSON.

Before commencing the design of a generating station an engineer has to consider the characteristics of the various available types of plant and systems of supply, the choice of which should be controlled by area of supply, density and customs of population, staple industries, geographical position, probable future of locality, tendency of its industries, and its relations with adjacent boroughs and localities. The plant to be discussed will be a steam turbo-alternator system with extra high-pressure alternating supply, this giving greater choice of sites. Fig. 1 shows an arrangement which would be suitable for such a station.

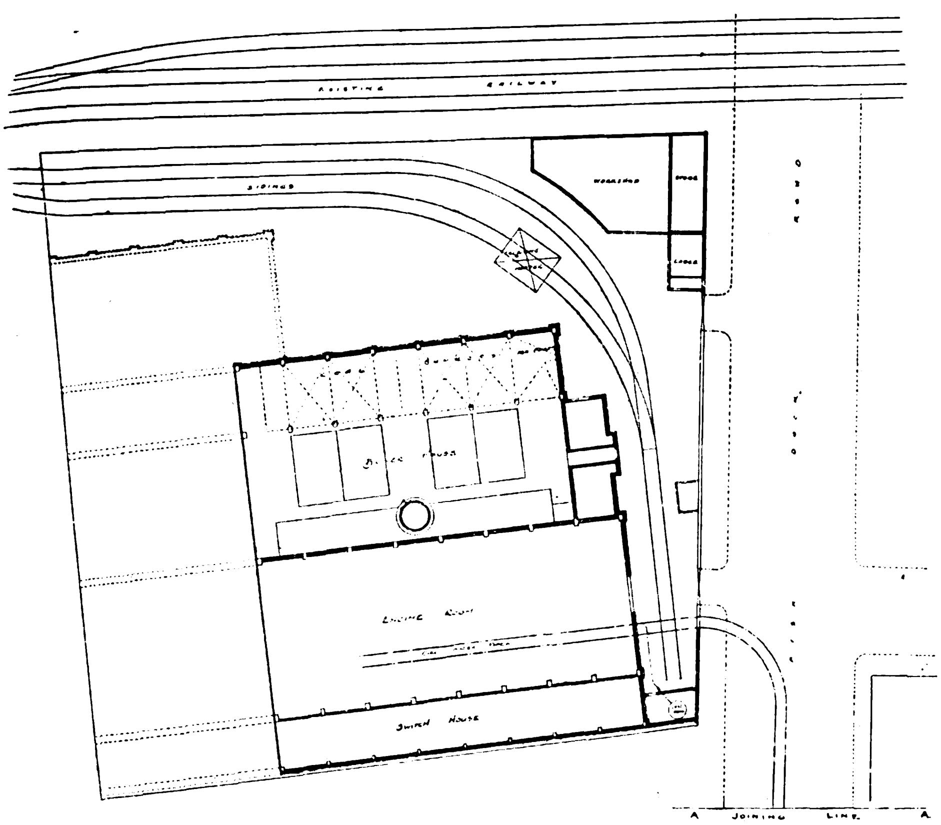

FIG. 1.—ARRANGEMENT OF STATION ON SITE.

In most large towns near rivers or estuaries, the railways run very near the water, therefore sites near the water possess a double advantage. Unfortunately, when such land is to be had at a reasonable price, it is usually found to be filled-in or made-up land, reclaimed within a comparatively recent period. Therefore, viewed from a foundation standpoint, it is always very bad, unreliable and, in many cases, contains the potentialities of chemical actions which will cause the authorities grave distress ere long with regard to pipes, cables, etc., which have been laid in the ground, if they are not specially and expensively protected. The problem of securing foundations giving a maximum of stability with a minimum of cost is, however, an interesting point in connection with such sites, and much could be said thereon.

First of all the cheapest system is the construction of a large floating or raft foundation, the main object of which is to distribute the concentrated weights of the plant and buildings over such an area that the resulting intensity of pressure is less than the safe bearing capacity of the ground. The commonest method was to use a plain concrete raft of considerable thickness, but there are very few cases where this has not developed cracks and unequal settlement of superstructures has occurred. Many such rafts have been reinforced with old tramway rails, but with little improvement.

We now come to piling foundations, and as wood piles, particularly in such grounds as the above, are liable to rapid deterioration, the tendency in view of the experience obtained latterly is to make use of reinforced concrete in the construction of piles. If carefully and properly executed no better foundations can be made, taking into consideration maximum stability with minimum weight and cost.

Among the attached sketches is a plan, Fig. 2, showing the arrangement of the piles and raft for a generating station at present being constructed by the author and for information it may be observed that the cost of the foundation, including the raft, the piles and reinforced foundation for the pipe track and reinforced pump chamber was $29,000. The depth from ground level to rock was thirty feet.

Buildings—The advantages of reinforced concrete construction may be carried beyond the actual piling, as it can be used to make a strong and light raft or floor over the heads of the piles and monolithic with them, forming a very complete and stable foundation for the superstructure. It lends itself to easily and cheaply conforming to the exigencies of the plant as regards differences in level of floors and foundations.

As regards superstructures they may be subdivided into the following classes of buildings:

1. Brick or stone entirely.
2. Reinforced concrete.
3. Steel skeleton with light brickwork filling.
4. Steel skeleton and corrugated-iron walls and roofs.

With regard to the first-named, such a building is unnecessarily heavy and expensive, and is the form generally used when an architect is allowed *carte blanche.* The heavy burden of capital expenditure unnecessarily carried by many stations has undoubtedly been largely contributed to by such useless extravagances, further aggravated in many cases by equally useless and more sinful ornamentation.

In reference to reinforced concrete superstructures, the author is strongly of opinion that they are not eminently suitable for the requirements of electrical generating stations. They are not cheaper than the style of building above referred to, the stability is in no way superior and, while certainly lighter, considerable inconvenience is met with in the fact that once up, the design can not be interfered with in the way of alterations without prohibitive cost.

Coming now to the composite building, consisting of a steel skeleton filled in with light brickwork, this appears at the present time to be the most perfect system of building, provided unnecessary ornamentation such as mentioned in connection with purely brick or stone buildings be eliminated, giving as it does a minimum of cost and weight when considered in connection with its probable life, reliability, strength, adaptability, neatness and appearance. If the insides of the buildings are to be lined for the sake of cleanliness, the author is of opinion that opalite or crystopal tiles are very much

[1] Abstract of a paper read before the Incorporated Municipal Electrical Association, Nottingham, England, June 30 to July 3, 1908.

superior in appearance, cleanliness and expense, to the ordinary glazed brick. In connection with the subject of cleanliness and internal appearance, a plea is here made for the boiler house. In many stations having splendid engine rooms, the boiler houses are unnecessarily dirty, gloomy and apparently neglected, for some unknown reason. This undoubtedly has a depressing effect on the human element of the boiler house, with a derogatory influence on the general efficiency. The author does not admit that under modern conditions there is the slightest excuse for the boiler house to be any dirtier than the engine room. It is by far the most important part of a generating station and should be treated as such, both in design and management.

A very great deal can be said in support of corrugated-iron buildings throughout. As regards their life, it is undoubtedly shorter than that of other buildings, but the question to be considered is whether their life, though short, is not amply long enough. In most cases the steel-skeleton building with corrugated-iron walls is the right form to use if the locality of the generating station does not require esthetic consideration.

Chimneys—The engineer has the choice of three main types, *viz.*, brick, reinforced concrete and steel. All the peculiarities of brick chimneys are well enough known and, provided great care is taken to spend some weeks after the work is finished in gradually heating up the chimney, there is, perhaps, nothing to beat it.

An interesting modern development is the reinforced concrete chimney. The author had occasion to go very carefully into the merits of this form of construction and came to the conclusion that there is a good deal to be said for it, because, owing to the simplicity of form, the before-mentioned disadvantages of reinforced concrete should not have an opportunity of attaining importance.

The author was surprised to find that in comparing steel chimneys with brickwork the result is so very doubtfully in favor of the steel chimney. Dealing with chimneys from 120 to 200 feet high, the steel chimney equals, and in some cases exceeds, in cost of the brick one, if the foundations are excluded, but as so many modern generating stations are built on very bad ground the foundations have to be particularly good in both cases so that the lower cost of foundations for the steel chimney is not in any proportion to its comparative lightness.

In reference to chimneys generally the great importance of a smooth interior is often lost sight of.

Types of Plant—There is very little choice left us under the present conditions in England, and as water power in any quantity is very rare, the case is limited to the consideration of gas or steam-driven prime movers. Being anxious to put in most up-to-date plant, and attain the best possible results in the supply of cheap power, the author was very desirous of using gas engines in connection with a new power station, and with much optimism made most detailed and careful inquiries from owners and engineers who were using such engines of modern types. Some six months were spent over this work as answers had in many cases to be got from abroad. The inquiries were limited to the larger units and latest installations. The results were extremely disappointing in that by a large majority opinions were unfavorable, principally on the grounds of unreliability, cost of upkeep, space occupied, first cost and the inability to meet sudden overloads of short duration. This being so, the question was reduced to the consideration of the reciprocating steam engine *versus* the steam turbine.

On inquiry there seemed to be no doubt as to the superior efficiency of the steam turbine, but in view of the common accusations of high cost of upkeep and liability to breakdown, visits were made to several turbine plants in the country, and the result was distinctly in favor of the turbine on all points, and as regards reliability, the vertical impulse type was

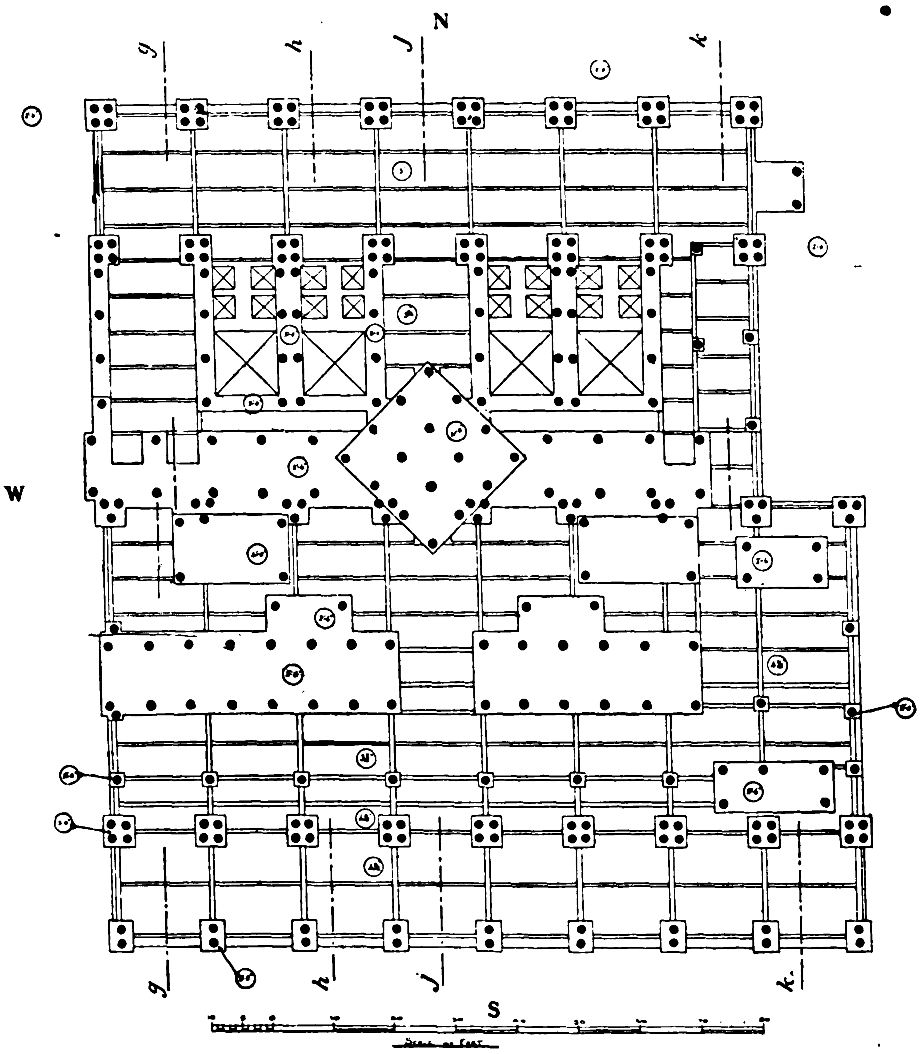

FIG. 2.—REINFORCED CONCRETE FOUNDATION OF STATION.

equal, if not superior, to the horizontal reaction type.

Generation of Steam—Under this head fall, to be considered for the larger electric stations, only two classes of boilers, *viz.*, the shell type (with ample economizer plant) and the water-tube type. Engineers will agree that a well-designed Lancashire boiler is about the best of its type, and in comparing it with the water-tube boiler it appears, in the author's opinion, to fall behind the latter.

The type of boiler should be chosen after careful consideration of the following points:

Size of boiler and space occupied.

Arrangement and size of grate and size

of combustion chamber in relation to the quality of coal dictated by local conditions.

Adaptability to a practical and efficient arrangement of superheater.

Simplicity in arrangement of tubes.

Ease of inspection.

Accessibility and cost of cleaning.

Liability to priming.

Cost of repairs and maintenance.

In view of the above the ease and speed with which standard parts can be got for repairs and maintenance is a serious consideration which should go a very long way in settling the particular plant to be used.

Before deciding the working pressure, the peculiarities of the type of turbine must be taken into consideration. Speaking generally for reaction turbines, a commercially high and quite successful efficiency is obtained with working pressure of from 160 to 200 pounds per square inch, with a minimum of practical difficulties. As regards superheat, however, the author is of opinion that in order to avoid any working difficulties and secure at the same time a maximum reliable efficiency the amount of superheat should be that necessary to attain a working temperature of 550 degrees Fahrenheit.

Much controversy has taken place as to the superiority of separately fired superheaters over those combined with the boilers. While the efficiency of the separately fired superheater is undoubtedly lower than that of a combined superheater, yet it has a great advantage in the possibility it holds out of maintaining a regular superheat at all loads. This is neutralized by the extra space, attention required and multiplication of pipes and valves.

Economizers—The development of the water-tube boiler has undoubtedly rendered the installation of these valuable adjuncts of less importance, and in particular, where cheap coal is being used they have a difficulty in justifying their extra cost. At the same time the author recognizes that in connection with turbine plants, where the condensed water is at such a low temperature, they have their uses in protecting the boilers from the well-known bad effects of a cold feed. Under ordinary circumstances economizers should be put in and careful attention given to their position and size to give the best results from the commercial rather than the strictly technical point of view.

Brickwork Settings—So far as their arrangement is concerned the principal rule to follow is to design the settings as compact, stable and accessible as possible and to shorten the lengths of all flues and passages to an irreducible minimum, giving good sweeping, smooth curves at every change in area or direction. Much trouble has been caused when the flues have been roofed with brick arches by the expansion and contraction of the latter causing the side walls to bulge, loosening the brickwork and sometimes causing the collapse of the lining. Heavy T irons and cast-iron plates get over this difficulty besides providing a smoother surface. To reduce the loss of heat by radiation is an additional reason for compact design. Two practical devices suggest themselves in this connection: One is to build the settings with hollow walls, packing the cavities with a suitable non-conducting substance, and another to face the outside with glazed bricks.

Built-in fittings, particularly dampers, must be carefully designed with a view to freedom from sticking in working, due either to their position, settling of brickwork, expansion or contraction. Instead of being as rough as they often are they should be most carefully fitted. Arrangements should be made to stop the leakage usually considered inseparable from dampers. The best cure for this is the use of butterfly dampers. Expansion being a considerable factor in such fittings sufficient clearance must be left to insure easy working when the boilers are being forced, as the inability to open or close a damper may have very serious effects.

Draft—If mechanical draft is decided upon by any designer, he has to choose between an induced-draft system, and what is called forced draft. If forced draft means brutal treatment of a boiler by forcing a supply of air for overworking an undersized combustion chamber, then the author would have none of it, but would substitute for consideration against induced draft a system of moderate pressure supply designed to control the air for combustion to a boiler within the limits of efficiency and without deteriorating effects. In considering such a pressure draft it is assumed that the air is supplied to a closed ash-pit, and that the pressure above the fire is equal to or very slightly below that of the surrounding air. The difference of pressure necessary to overcome the resistance of the boiler flues and economizer would then be provided by a comparatively short chimney. It is submitted that the pressure draft is superior for the following reasons: In case of any leaks in the settings, the efficiency of the draft will be preserved, and as the difference in gas pressure between the interior of the flues, etc., and the surrounding air is much less, harmful air leakages will be avoided. If the quality of the coal is such as to require frequent opening of the fire-doors to break up clinkers, etc., the inrush of cold air with consequent loss of efficiency and damage to brickwork and boiler will be avoided.

The size and consequent price of the plant is smaller.

Speaking generally of draft the installation of a chimney of a capacity sufficient to deal with the normal full load of the plant is recommended because this method is, after all, the most efficient, simple and reliable, and appears to be cheaper in first cost. The author does not condemn the use of mechanical draft for all circumstances; the above recommendation only refers to the normal conditions while a power station is going easily. During the erection of extensions nearly all power stations are pressed, therefore it is recommended that everything should be constructionally ready for the installation of a pressure or induced draft, not in recognition of the superior economy of such apparatus, but in appreciation of their temporary utility in producing a desirable margin of power.

Coal-Handling Plant—It is only after a power station has attained considerable size that any superiority in the mechanical or automatic handling of coal is made manifest. Quite a number of stations are fitted with such plant, but apart from handiness they do not pay commercially. The question is entirely one of putting the standing charges and maintenance cost of such plant against the saving in labor and probably increased efficiency of the mechanical stoker. As this paper refers to larger stations, they will be considered as necessary, and it will be taken for granted that a railway siding runs into the station premises, with facilities for feeding the said sidings with cars from the wharves if not near enough for transporters.

The first questions to consider are the methods of filling the feed hopper, and the position of the latter relative to the necessary conveyer. A not uncommon difficulty in made-up ground is the limited depth to which one may go with the hopper. If the required depth is likely to be below the water level it is desirable to sink a water-tight cast-iron tank and line the same with concrete. As to the means of emptying the cars there are four methods available, *viz.*, by hand, bottom door emptying, end tipping and side tipping. The choice between the last three necessarily depends upon the type of cars available and the speed of service.

Leaving the worm and belt conveyers out of the question for this work practically limits consideration to the well-known bucket type and the equally familiar scraper type. The author's opinion favors the bucket type in spite of its considerably higher cost for the following reasons: Longer life, neater and cleaner work, less wear and tear, less power used, less noise, increased reliability, less breakage of coal; in short, less total cost in working.

As to the bunkers, although steel bunkers are convenient, light and in more general use, yet a case is clearly made out for the serious consideration of reinforced concrete. An estimate of the probable saving in cost obtained from four known cases approximates twenty-five per cent for equal capacities.

In designing the bunkers special attention should be given to the arrangement of the compartments with a view to storing different classes of coal to be easily drawn from by the engineers at their discretion. Such facilities are great convenience and have a considerable effect on the total economy of the station.

As regards the measuring of coal, the conflicting results obtained where the weighing system is in vogue and the impossibility of tallying, however accurate the machines, decide in favor of the volumetric measuring as against weight measurement. The results thus obtained will compare more consistently. This only refers to boiler-house measurement, and not to the measurement of coal supplied to the station, which, of course, must be weighed.

Mechanical Stokers—The different requirements which must be fulfilled by any satisfactory mechanical stoker are: Low first cost, reliability and simplicity, cost of upkeep, cost of power for working, accessibility and ease in replacing damaged parts, extent of control over rate of combustion, suitability to the type of boiler to be adopted, smokelessness.

After consideration it will be found that the number of stokers that will answer the above requirements satisfactorily is very limited, and so far as use with water-tube boilers is concerned the author favors chain-grate close-linked stokers.

Ash and Soot Handling Arrangements—These should be designed so as to keep ash and soot out of and away from the boiler house proper. The ash basement under the boilers or firing floor is the proper place for dealing with such refuse, and it is quite simple to load it into the conveyer with a minimum amount of scattering or dust. The cleaning of the economizers ought to be arranged for in the same way, giving easy connection with the conveyer. In reference to this matter there will be noted in the accompanying plan, Fig. 3, an economizer arrangement which was intended for use with very small, cheap coal. Specially designed screw conveyers are fitted in sloping-sided compartments, forming the floor of the economizer chamber. This will prevent the annoyance of shutting and cooling down of the economizers for the necessary frequent cleaning and will result in a considerable saving of labor.

Feed Pumps—Where a pump is to work at a full-load rate for long periods the superior efficiency of the electrically driven pump would point to its adoption. Such pumps, however, do not lend themselves easily and economically to regulation over wide ranges and this, combined with their appreciably higher first cost, militates against their use under conditions of variable loads. It is necessary in any case to install one steam-driven feed-pump at least, in a generating station for use in emergencies when electrical power is not available. Probably the best policy to follow is to start the first installment of plant in a station with steam pumps and use electrically driven pumps for the extensions. Although feed-pumps are more frequently located in the boiler house there is a great deal to be said for situating them in the engine room. The arrangement of feed-piping can often be simplified and made more direct and the pumps are likely to receive more attention than they would get at the hands of the firemen. It is important in such cases to

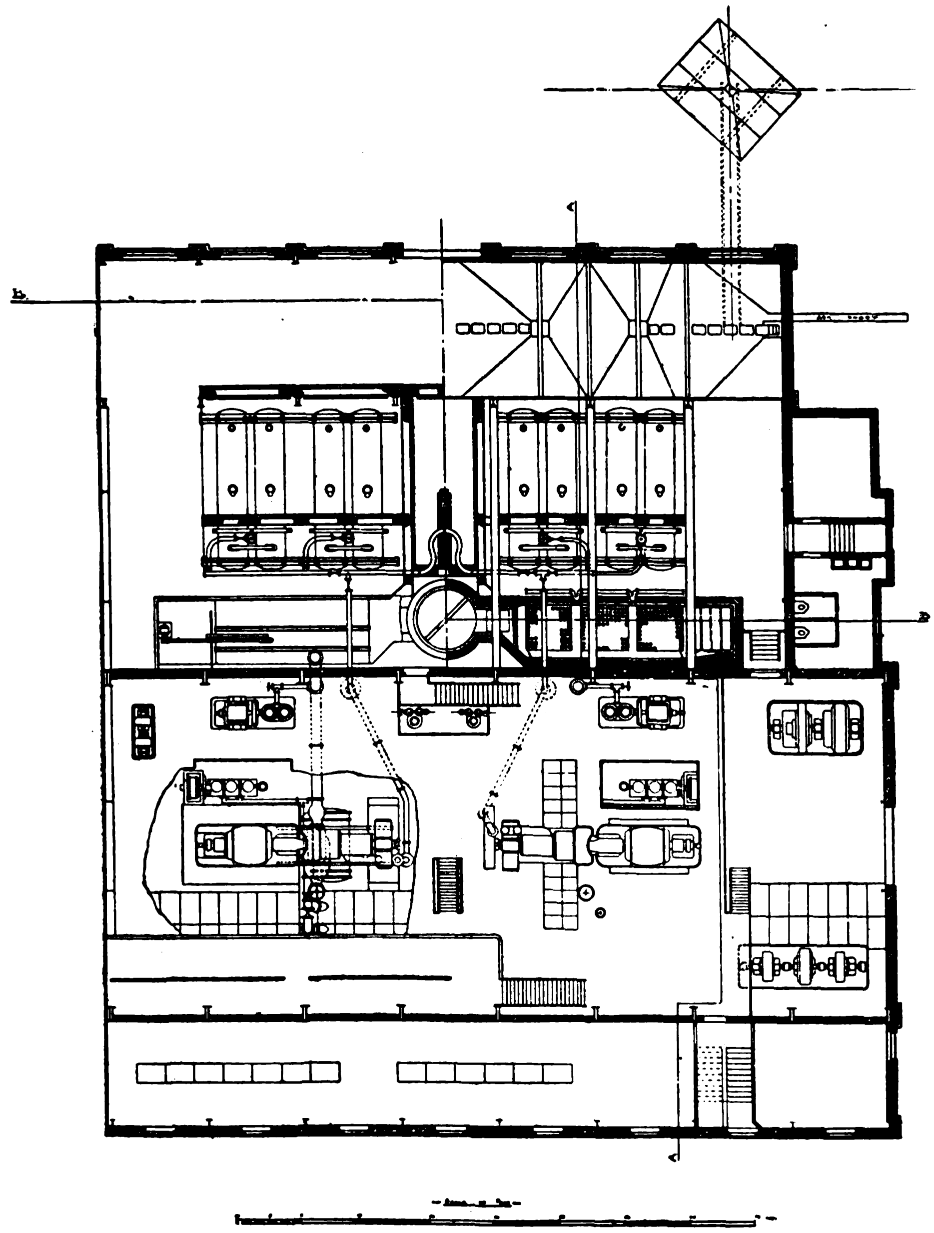

Fig. 3.—Layout of Station Equipment.

arrange for convenient regulation from the boiler house.

Engine-Room Layout—In dealing with the layout of the engine room with turbine plant of the horizontal type, the first thing is to decide whether the axis of the turbines shall be parallel to the length of the engine room or across it. With the larger sizes of turbines of 1,500 kilowatts and above, and a single row of boilers parallel to the engine room, considerable space can be saved by the first arrangement. Before taking the utmost advantage of this, however, it is well to forecast future possibilities in the way of other types of plant, such as vertical turbines, gas engines, etc., as the span and height of the crane may otherwise greatly handicap the choice of plant required for extensions. With regard to the position of the condensing plant, this is now almost universally situated immediately below the turbines, on account of the importance of reducing the frictional resistance to the flow of the exhaust steam, and it also minimizes chances of leakage by diminishing the number of joints. The condensers can either be placed lengthwise with the turbines or across; the former gives a very compact arrangement with the turbines along the length of the engine room. In condensers of the *contra-flo* type, however, the steam inlets are situated eccentrically, and such condensers must, therefore, be placed across the turbine.

With regard to the air-pumps there are two or three modifications to choose from, *viz.*, the simple air-pump or two separate pumps, one for dealing with air and vapor, the other for the water, or thirdly, a vacuum augmenter in combination with the air-pump. The absolute pressures attainable respectively in the condenser decrease in the above order, the extra complications being intended to increase the density of the air and vapor before it is dealt with by the air-pump, which is done by cooling in the one case and by a preliminary compression with a steam jet pump in the other. The practical advantage of the possible increase in vacuum by the use of such methods is rather doubtful except, perhaps, in the case where the available amount of cooling water is limited and its temperature is high.

It will also be found that this apparatus requires to be below the level of the condenser, and that the necessary depth can not always be given owing to complications of sewers and liability of flooding. Facilities for the cleaning and replacement of tubes should not be lost sight of in the design.

Circulating Water-Pipe System—To reduce the power required for pumping the circulating water to a minimum, the outlet end of the discharge pipe should be below the level of the source of supply, so that the arrangement forms a species of syphon. Precautions are necessary to deal with air liberated from the water or leaking in at joints if the top of the syphon is far above water level, otherwise the syphonic action will soon cease. The advantage of the syphonic effect is, of course, limited to about thirty feet (practically it may be found to be much less), and in cases where the water has to be raised to a considerable height, the recovery of power rendered possible by the use of turbines situated near the lower end of the discharge pipe, and driven by the water on its return, merits consideration. As the integrity of the circulating-water system is of such vital importance in a steam-turbine installation, every care should be taken in the laying and jointing of the pipes, and the latter should be specially protected from corrosion if the ground is bad. Trouble has been experienced in cases where cast-iron pipes have been embedded in solid concrete with breakage due, probably, to expansion and contraction with the varying temperatures of the discharge water. A form of pipe which possesses considerable advantages for this work is one constructed of reinforced concrete. Such pipes are cheap and durable, and can be molded practically in any desired shape. In any case substantial foundation must be provided for the pipes to obviate subsidence, and if the ground is soft, piling becomes necessary.

Main Steam and Feed Piping—The author desires to advance a plea for reducing duplication of pipework to an absolute minimum and securing reliability by simplification, thoughtful design, careful erection and the use of the very best materials. The simplification and reduction of the amount of steam piping has its effects on the coal bill, while the reduction in the number of valves and joints is correspondingly beneficial in economy of maintenance. The diameter of the main steam pipes can advantageously be reduced when used for superheated steam. When turbines are used there are additional reasons, as the flow of steam is more uniform and the retention of temperature of superheat is of greater importance than a slight reduction in steam pressure.

Generators—The modern standard designs of generators of the best makers are very similar and their differences do not entail any special features in the design of a station. The question of efficient ventilation has risen into great prominence since the advent of the turbo-generator, and ducts are generally formed in the concrete foundations for this purpose. If possible it should be arranged that these ducts lead from a cool space in which the air is still, dry, free from oily matter and has had time to deposit some of its dust. If air is drawn specially from outside the building, the position of its entrance should be carefully considered in connection with this question of dust, and filters may be used.

Auxiliaries—The use throughout a generating plant of continuous-current motors for driving auxiliaries is recommended in cases where direct current is to be distributed in the locality of the generating station, as it is very convenient to have a storage battery reserve for this class of work and economical adjustment of speed has advantages.

Switchgear—In moderate and large-sized stations the best system is to isolate the whole of the high-tension gear in special chambers, the operation being effected from a gallery overlooking the engine room through the medium of electrical control. The cellular type of board is to be preferred, and as much space as can be afforded should be allowed for the gear. This is a strong reason for arranging the switch chambers along the side of the engine room, rather than across the end; besides this method allows of some simplification in the connecting cables. The bus-bars should be divided by means of section switches so that any part may be made dead for inspection or repair without interference with the supply. Too much thought can not be bestowed in obtaining a safe working arrangement. In a system which is being carried out by the author the doors of the compartments containing the feeder isolating switches are provided with double locks. One key will be kept by the station department and one by the mains department. Whenever any cable is required to be disconnected for testing or repair, the isolating switch will be opened and the compartment locked by both parties. The cable then can not be made alive again except in the presence of both the departments concerned. Facilities for earthing parts of the gear should be provided as a safeguard against their becoming charged by leakage or otherwise, while persons are working on them. It is almost universally acknowledged that oil-break switches are the only type that should be used for breaking high-tension circuits, and their breaking capacity should be chosen with reference to the total kilovolt-ampere capacity of the station on a momentary short-circuit.

REVIEWS OF CURRENT ENGINEERING AND SCIENTIFIC LITERATURE

The Nature of the Gamma and X-Rays.

Some time ago W. H. Bragg expressed dissatisfaction with the generally accepted ether-pulse theory of the γ rays. This theory does not seem to him to account for a number of phenomena observed in connection with the production and action of these rays, and he suggests, in place of it, what he calls the "neutral power" theory. In this, an electron is supposed to be associated with a positively charged particle, so that no external electric or magnetic forces will affect the pair in its motion through space. Working on this theory, he has made an investigation of the secondary radiation produced by γ rays and he believes that all the facts which he has noticed are easily explained by his theory. The investigation has been continued, and he here gives a general summary of his results. When the γ radiation is diminished in quantity, as it passes through matter, β radiation appears in its place, moving at the outset in the original direction of the γ radiation, and subsequently undergoing scattering in the ordinary manner of β rays. The penetration, and therefore the speed, of the β radiation thus produced increase with the penetration of the γ radiation to which it is due. The speed of the radiation does not depend upon the nature of the atom in which it arises. In the case of radium, at least, the speed of the β radiation is nearly equal to the speed of the normal β rays emitted by the radium itself. When very hard γ rays traverse matter, their absorption, and therefore the production of β rays, are almost independent of the atomic structure of the matter. Softer rays are affected by atomic structure. They are more absorbed by light atoms for equal weights of absorbing screens. The softer the rays, the greater is this effect. If there are any secondary γ rays, the ionization which they produce is negligible as compared to that produced by the secondary β radiation. All of these facts can be explained very simply and directly on the "neutral pair" theory; but an explanation on the ether-pulse theory is not easy. On this theory, both the electron and the electron's energy are supposed to be drawn from the atom, the γ ray merely starting the action. This does not account for the direction in which the radiation starts, and the differences in velocity which may be observed. Another difficulty is the insufficient intensity of the γ rays to produce these effects, if they be supposed to spread out in an ever-widening surface. To overcome this difficulty, Thomson and Campbell have suggested that the γ ray does not spread out, but travels as a parallel beam. But this seems rather to complicate the theory of the subject. The "neutral pair" theory seems to the author the simplest and most satisfactory that has yet been suggested, and he points out that this explanation will hold with the X-rays as well.—*Abstracted from Nature (London), July* 23.

Electric Traction on the Brighton (England) Railway.

A brief summary of the particulars of electrical working which will be shortly put into service on the suburban lines of the London, Brighton & South Coast Railway are given here. The section of the line at present being electrified extends from Victoria station to London Bridge, a distance of nearly nine miles. The total length of track is nearly twenty-three miles. At the Victoria station there are five platforms and two through lines, and at London Bridge station there are six platform lines electrically equipped. The improved service will require seven working trains and one spare one, each train comprising two third-class motor-cars, with baggage and motorman's compartments, each equipped with four 125-horsepower motors. The motor-cars will be placed at each end of the train with a first-class trailer in between. A ten-minute service will be given. The time required for the entire run will be twenty-five minutes, including stops, which may be compared with the thirty-six minutes at present taken by the same trains. A new type of car has been adopted which has communicating compartments, enabling passengers to pass from one part of the car to another. The electrical equipment is arranged so that no one can come in contact with any high-tension apparatus. In fact, this is only accessible when the current is cut off and high-tension connections connected to the ground. The overhead conductor for this line is a heavy grooved solid wire, one-half inch in diameter, supported on the double-catenary system. The messenger wires are suspended in massive porcelain insulators, tested to ten times the working pressure. Throughout the entire overhead construction a factor of safety of ten has been adopted. The overhead conductor is divided into sections at each station by means of specially constructed switchgear in fireproof cabins. Thus it is possible to isolate any section of the line to make repairs or to prevent accidents. A complete system of telephone connections exists between the cabins and signal houses. A duplicate feeder system has been supplied throughout the line to insure reliability, and a special system of cables was installed to bring the voltage drop in the return circuit within the requirements of the board of trade. The energy will be supplied to the Brighton Company from the London Electric Supply Corporation through mains connected to the Deptford station. There are four 2,000-kilowatt generating units installed there, one of which it is thought will be sufficient to carry the normal load. Some rather perplexing difficulties were encountered in installing the overhead equipment. At certain points bridges are so low that the overhead conductor could not be more than fourteen feet from the ground. In the station it was necessary to place it twenty-one feet from the ground, because railway employés have to work on the roofs of the trains, which made it necessary to design a special form of collector bow capable of working satisfactorily at high speeds through a range of between twenty-one and fourteen feet. Special devices have also been necessary at the low bridges to prevent accidental contact with the high-tension wires.—*Abstracted from Electrical Engineering (London), July* 23

A Quantitative Determination of the Radium Emanation in the Atmosphere.

About six years ago Elster and Geitel showed that an actively charged wire exposed for a few hours in the air received a radioactive deposit similar in character to the quick-changing radium products. The first attempt to measure the amount of radioactive matter in the atmosphere was made by Eve in 1905. His results varied greatly, being for one determination 82×10^{-12} and for another 287×10^{-12} gramme to a cubic metre of air. Eve has since described a new method of determining directly the amount of radium emanation in the atmosphere, which makes use of the property of cocoanut charcoal to absorb the emanation at low temperatures. This gave results of the same general magnitude, also varying greatly among themselves. It occurred to G. C. Ashman that a good opportunity for quantitative measurement was offered by the fact discovered by Rutherford that the emanation could be condensed at the temperature of liquid air. For this purpose the author drew air from out of doors at ground level, passed it through purifying solutions, then condensed it in a coil of copper tube immersed in liquid air. It was finally collected in aspirators made of carboys of known capacity. Two hundred litres of dry air, free from carbon dioxide, could be drawn through the coil at a moderate rate in six hours. At the end of that time the coil was allowed to heat up, and the volatilized emanation was transferred to a standardized gas electroscope. The results of four experiments varied from 45×10^{-12} to 200×10^{-12} gramme of radium to a cubic metre of air—variations comparable with those of Eve's experiments. Thinking that these variations might be due to incomplete condensation of the emanation, a second coil similar to the first one was joined in series with the latter. Both were immersed in liquid air. Upon repeating the experiment, the emanation from the first coil corresponded to 51×10^{-12} gramme of radium to the cubic metre; while the second coil did not show a trace of the emanation, thus clearly proving that it was entirely condensed in the first coil. This seemed to indicate that the variations in results were really due to variations in the amount of emanation in the air at different times. To determine this point, simultaneous duplicate experiments were conducted, the air being drawn through two coils in parallel at the same time. In one experiment it was found that each of two coils through which equal amounts of air had been passed simultaneously gave results corresponding to 131×10^{-12} gramme of radium, clearly showing that the variations were, as supposed, really those occurring in the atmosphere. The author finds that his mean result is about twenty-five per cent higher than the mean value found by Eve. This may easily be due to variations in the quantity measured. His highest determination was made with air immediately after a heavy rain and a general thaw, following several weeks of freezing weather, with an unusual covering of snow on the ground. Six experiments made at Chicago showed that the average amount of radium emanation per cubic metre of air could be maintained by 1×10^{-10} gramme of radium.—*Abstracted from the American Journal of Science (New Haven), August.*

The Fire on the Lancashire & Yorkshire Railway.

An abstract is given here of the report issued by A. B. Trotter of the British Board of Trade, on the fire which broke out on the trailer of a train of the Liverpool & Southport Railway last April. This fire started after the train had left a station. No one was injured. The fire is divided into two kinds: The primary fire, due to and supported by and in the immediate neighborhood of the electric arc which started it; and the secondary fire, which spread by ordinary combustion when inflammable woodwork had caught fire. The cause of the primary fire is divided into two considerations: The defect, undoubtedly a short-circuit from the positive cable to earth, and the persistence of the electric current after the substation circuit-breaker had automatically opened. The effects of the arc were confined to a distance of a foot or so from the spot where the fire broke out, below the floor and at the point where the cables turned to rise up and pass through the floor. The probable cause of the fire was the main trolley cable which was insulated with pure and with vulcanized rubber taped and braided with fire resisting braidings. These and other cables are bunched in a wooden casing lined with thin uralite. Where they bend upward the uralite is cut away so that the braiding of the cable rests against the wood. After passing through the floor the cables are well taped and compounded; but this protection against moisture is inflammable. Mr. Trotter criticizes the bunching of the cables in a common trough and the cutting away of the uralite so as to expose the wood, and compares this practice with that of the Northeastern Railway, where each cable is carried in a separate iron pipe and the pipes themselves are arranged not to cross each other, and all are carefully grounded to the frame. To prevent the collection of moisture in these pipes, it is recommended that they be sealed up by means of split wooden ferrules driven tight around the cable. The arc which started this fire was very severe, and lasted two or three minutes. Several pounds of iron were melted by it out of the frame. The cause of the persistence of the arc is said to have been the replacing of the circuit-breaker on the converter at the station after it had come out the first time. As the line breakers did not come out, no serious trouble was suspected, and current was still supplied to the car from more distant substations. To distinguish between simple overloads, grounding of the feeders, and arcing of the kind which causes fire, Mr. Trotter suggests that a telephone receiver be connected in an induced circuit and in shunt with as much of the conductor as is available at the substation. It might in this way be possible to distinguish between the variations in current due to running of the motors, the comparative silence due to leakage, and the characteristic roar caused by an arc. The report is concluded by recommending certain changes in the methods of running the cables on the cars so as to protect them from the weather and the planning of the feeders and switching devices with a view to limiting to each section the current supplied to that section, with a reasonable margin for overloads. Such sections should, if possible be of such length that there would be but one train starting on them at a time.—*Abstract from Electrical Engineering (London), July 16.*

Street Railway Earnings.

A director of two of the largest street railway systems in the United States says, according to the *Wall Street Journal:*

"An important lesson learned from the past ten months of business depression has been the demonstrated stability of street railway earnings. Many of the large railroads of the country have shown shrinkage in gross for the year ended June 30 of twenty to twenty-five per cent. Street railway earnings, on the other hand, have in such cases as the traction systems of Boston, Chicago, Philadelphia and St. Louis shown small gains or at the worst slight losses of less than three per cent.

"In the return of prosperity the street railways will start a lap ahead of the railroads."

Edison Companies' Convention.

It is announced by President Alex Dow that the annual convention of the Association of Edison Illuminating Companies will be held this year at the Hotel Aspinwall, Lenox, Mass., on September 15, 16 and 17, with committee meetings on the 14th.

INDUSTRIAL SECTION

ILLUSTRATED DESCRIPTIONS OF NEW AND STANDARD ELECTRICAL AND MECHANICAL APPARATUS

Heavy Traction Gearing.

The development of modern electrical railway systems has involved a continued increase in the size and weight of both cars and equipments in order that the high speeds now demanded in this service may be maintained. As a consequence of these conditions the augmented stresses to which the teeth of motor gearing are subjected, combined with the limited space available, have rendered the strength and wearing qualities of gears and pinions important factors in the cost of operation.

In order to successfully meet these conditions without an excessive increase in cost, the General Electric Company, Schenectady, N. Y., has developed a highly efficient gear which consists of a forged-steel rim or tire mounted on a cast-steel centre so as to form what is practically a one-piece gear, as a pressure in excess of 200 tons would be required to force the rim off the cast centre. This combination not only gives added resistance to wear on the gear teeth, but enables a rim to be replaced when finally worn out, with a minimum of delay and expense.

The success with which this form of motor gear has met in actual service is indicated by the fact that during the past three years it has been installed in original equipments on many of the most important electric railway systems in the United States, among these being the Interborough Rapid Transit Company, the Hudson & Manhattan Railway Company, the New York, New Haven & Hartford Railroad, the West Jersey & Seashore Railway Company, the Scioto Valley Traction Company, etc., in all of which the mileage records show graphically the increase in efficiency obtained by its use.

As a further development along these lines the General Electric Company conducted a series of exhaustive experiments with the object of obtaining great strength with a uniform quality of metal, and it has now developed a pinion having remarkable physical characteristics of tensile strength combined with a high elastic limit. These qualities are obtained without in the least sacrificing the element of toughness so essential to the continued operation of heavy equipments.

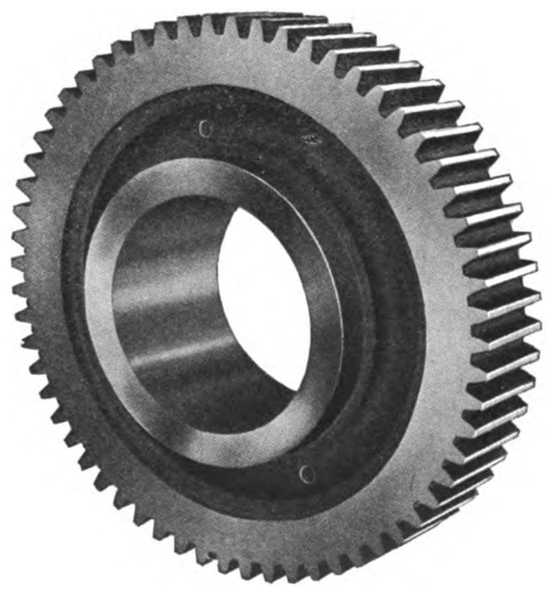
This pinion is known as the General Electric "New Long Life Pinion," grade "F." This special (grade F) steel, after being machined, is treated by a process which avoids any possibility of distortion or internal stress while cooling.

The increased strength obtained by this process insures an ample factor of safety over the stresses to which the pinion teeth are subjected in ordinary service, while the hardness of the steel minimizes the effects of abrasion and thereby reduces the wear from friction. As a result there is a notable saving in the labor cost of renewals, and, in addition, the item of expense caused by interrupted service is materially reduced. There is also obtained a more nearly even wearing of gears and pinions.

This latter point is worthy of serious consideration, as the ordinary cast-steel gear usually outlasts three soft pinions, with the result that during a considerable proportion of its life it is operating with worn pinions and under conditions of low efficiency, which add to the mechanical strain on the motor. In addition to this, the vibration and noise so frequently associated in the minds of the public with electric railway service are largely due to the unequal wearing of gears and pinions. The (grade F) pinion should, under average conditions, last as long as the cast-steel gear and, as a result, outwear three ordinary-grade pinions, with an obvious saving of the cost of two renewals as well as insuring operation at maximum efficiency.

The general appearance and method of assembly of steel-tired gears are shown in the accompanying illustrations. In addition to this standard design, the General Electric Company manufactures the grade "F" steel rim or tire so that it can be mounted on various forms of extended car-wheel hubs or steel flanges to meet special conditions.

Steel Tire Gear Used by Interborough Rapid Transit Company with G. E.-69 Motors.



G. E. Railway Motor Gear, with Steel Tire and Cast Steel Hub.

Thermostatic Magnet Protector.

Appreciating the opportunity which exists for a reliable magnet protective device which would not be dependent upon an electromechanical mechanism, the designers of the thermostatic magnet protector, illustrated herewith, after a long series of exhaustive tests under actual service conditions, finally adopted this form as embodying all the desirable features called for in a protective device of this nature.

The device consists of a spring clip mounted on a metal holder and locked in position by means of a small metallic "button." This button is composed of a special alloy, which will melt at a predetermined temperature, and in melting releases the spring clip, which instantly opens the circuit and cuts the apparatus being protected out of circuit—thus preventing a burnout. It should be understood that this button carries no current and does not act as a fuse, but is dependent for its operation upon the actual temperature of the apparatus to be protected.

The thermostatic magnet protector was primarily designed for the protection of arc-lamp coils, and in this field found its widest application. There are many so-called indestructible magnet coils, but they frequently burn out under actual service conditions and generally do more or less damage to other parts of the apparatus.

By placing the thermostatic magnet protector in series and with the magnet coils, it will be found impossible to damage the coils, as this device will always cut the lamp out of service before a dangerous temperature has been reached.

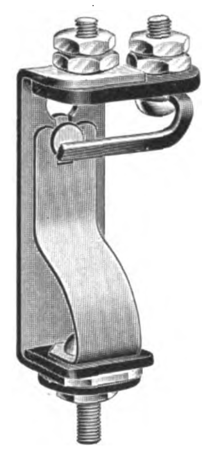
Arc-lamp repairs are expensive, both in material, time and loss of service, and any device which will prevent this expense will be appreciated by users of arc lamps.

The following report, dated June 8, from the Commonwealth Edison Company's laboratory, on the operation of this protective device, is of interest and clearly illustrates the inherent reliability of this new device which is being placed on the market by the Central Electric Company, Chicago, Ill.:

"We have made numerous tests on arc lamps equipped with the thermostat protective device, and find the following conditions:

"The thermostat, situated as it is in the shell of the lamp, is actuated by the temperature of the air surrounding the coil. This air, in the case of the direct-current lamp, is not heated nearly so much by the coil as it is by the resistance spools. In each case the temperature of the air surrounding the thermostat was within two or three degrees of 135 degrees centigrade, as measured by the thermometer when the circuit was opened by the thermostat. In order to find out whether the external temperature of the coil was higher or lower than the internal temperature, the resistance of the coil was measured at the same time that the temperature readings were taken. With the current in the lamp approximately twenty-five per cent above normal, and with the surrounding air at about twenty-two degrees centigrade, it was found that the mean temperature of the coil as determined by the resistance method was approximately eight to ten degrees centigrade lower than the external temperature of the coil.

"To determine the effect of lower external temperatures and wind upon the operation of the thermostat, and the relation of mean coil temperature to external temperature of the coil, under these conditions, a fan was arranged to throw a current of air upon the shell of the lamp. The current in this case was also kept at about twenty-five per cent above normal, and the temperature, by thermometer placed on the outside of the coil, compared with the mean temperature as obtained by resistance method. In this case it was found that the mean temperature of the coil as found by the resistance method was four or five degrees higher than the temperature of the air surrounding the thermostat. With extreme weather conditions it is possible that the difference would be much greater.



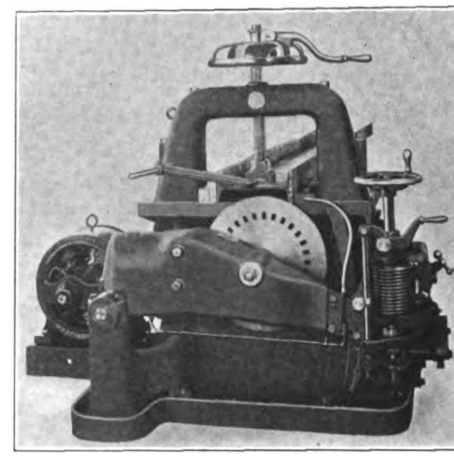
THERMOSTATIC MAGNET PROTECTOR.

"The thermostat will not operate under ordinary operation of the lamp, but will blow within one or two minutes after the temperature of the surrounding air at the plug has reached 135 degrees centigrade.

"On each test made the thermostat has opened the circuit satisfactorily."

Motor-Driven Cold-Metal Saw.

The use of small cold saws for cutting off all sizes and shapes of metal work has become very general in a great variety of establishments, not only because of the utility of the saw itself, but also because



MOTOR-DRIVEN COLD-METAL SAW.

of the fact that individual motors have been most successfully fitted to the saws.

In a great many establishments it would be almost impossible to locate the saw so that it could be conveniently used by the workmen. In the average machine shop one or more saws are required in the stock room or some other equally inconvenient place for mechanical drive. Here the use of a small motor on the saw permits the location to be selected without reference

MOTOR-DRIVEN COLD-METAL SAW.

to any requirements except the convenience of putting work through.

In structural iron works the self-contained unit of motor and saw can be picked up by a crane and carried to any part of the building or yard. Similarly the use of the motor-driven set is found very advantageous in a great many plants.

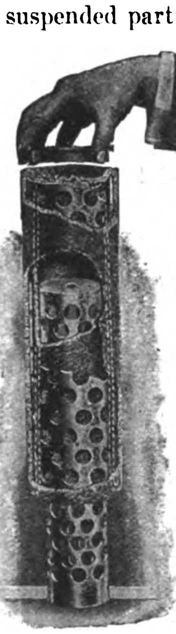
The cold saw illustrated, which is one that does not require a bevel gear, is especially adapted to motor drive. The saw is manufactured by the Lea Equipment Company, of New York city, and is fitted with a Westinghouse shunt motor. The size shown requires a two-and-one-half-horse-power motor and is capable of cutting eight-inch round stock. A Morse silent chain is used to connect the motor to the saw, in preference to gearing, as experiments have shown the former to be more satisfactory.

It is necessary to be able to adjust the speed of the saw in order to cut different metals with maximum efficiency. For instance, experience has shown that the peripheral speed of the saw should be fifty-two feet per minute with a very coarse feed for structural iron, machinery steel and metals of this class. For annealed tool steel a lower speed of but thirty-seven feet a minute is the most efficient. This same speed is also used on Krupp's chrome nickel steel. In order to obtain these speeds, an adjustable-speed motor with speed range of one and one-third to one is used, with a speed-controlling rheostat. It is only necessary to move the handle of the controller to obtain any desired speed.

Feed-Water Filtration.

The accompanying illustrations show the Blackburn-Smith feed-water filter and grease extractor, a device which is installed in the feed line and subjects all entering water to double filtration through separated terry cloths. If an open heater is used the filter is placed between the pump and the boiler, but if the heater is of the closed type the filter is installed between the pump and the heater, in order that the suspended particles will be caught before they can settle on and reduce the efficiency of the heater surface.

This filter is very effective in removing mechanically suspended particles from the water supply, for removing all particles of oil, grease and dirt from the lines, and anywhere that the condensed exhaust returns from steam-heating systems, condensers, drying coils, etc. By removing the scale-forming matter the filter reduces repair bills and also effects a saving in coal bills and bills for water supply. Terry cloth can be cleaned and used over and over again, and the filter costs practically nothing for maintenance.



REMOVING THE FILTERING MEDIUM.

Where muddy water is to be filtered, or where oil or grease is present in large quantities, a better arrangement is to run two or more filters in parallel. Each filter can then be thrown into service or cut out at will, and any filter can be cleaned while the plant is running, and no impurities reach the boiler.

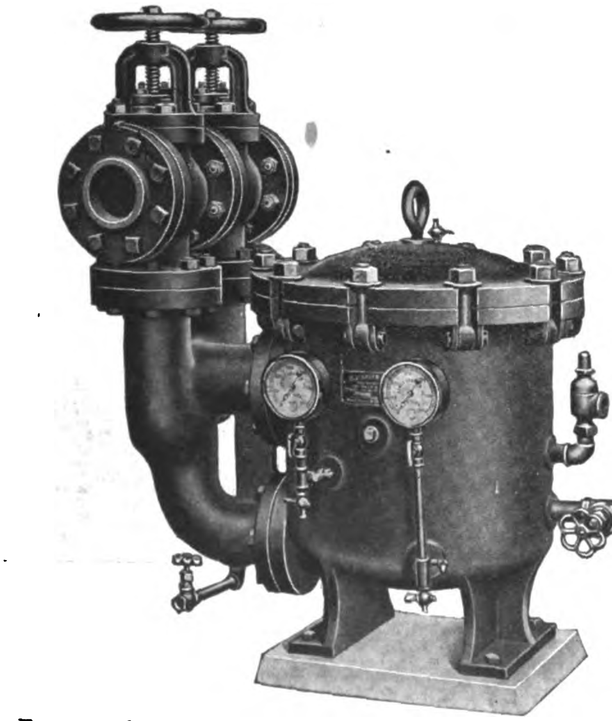
The water passes from the feed pump into the filter inlet, through the upper or filtering chamber, then through the filter cartridges into the pump chamber, and from the pump chamber through the outlet to the heater or boiler.

The water passes through the cartridges with very little friction, but in the course of time, as the foreign material accumulates on the filtering cloth, some resistance will result. When the difference of pressure, as shown by the pressure gauge, increases to twenty pounds per square inch, the filter should be cleaned. A water relief valve automatically prevents the building up of excessive pressure in the pump discharge line.

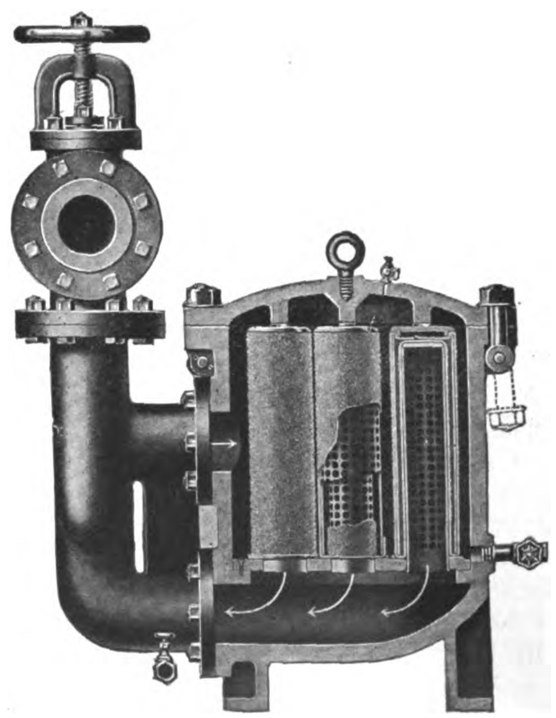
The valve chamber is made right-hand or left-hand, as desired, so that the filter may be set on either side of the line. Both the main valves are in a straight line with the feed pipe.

The number of cartridges in each filter varies with the size of the unit. Each cartridge consists of two concentric cylinders of heavy perforated brass tubing covered with linen terry. The lower end of the inner cylinder is expanded into the partition which separates the filtering and outlet chambers, and the upper end is covered by a perforated brass cap.

The Blackburn-Smith filter is made by James Beggs & Company, 109 Liberty street, New York city.



EXTERIOR VIEW OF CARTRIDGE-UNIT TYPE FEED-WATER FILTER.



SECTIONAL VIEW OF CARTRIDGE-UNIT TYPE FEED-WATER FILTER.

Troy Electrical Company's Iron-Clad Fittings.

The accompanying illustrations show several fittings which have been placed on the market by the Troy Electrical Company, of Troy, N. Y. Fig. 1 shows the new "Teco" iron-clad standard service or entrance switch. This is made in sizes ranging from eight and one-half by four and one-half by four and one-half inches to thirty-one and one-half by ten by five inches, for double-pole, triple-pole and four-pole switches, for open work, for half-inch, three-quarters-inch and one-inch conduit.

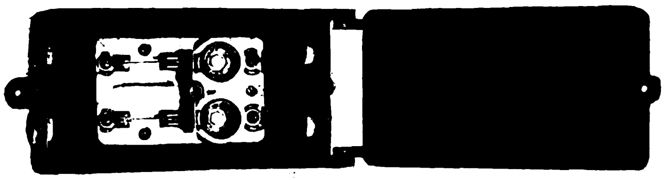


Fig. 1.—"Teco" Iron-Clad Standard Service or Entrance Switch, No. 120.

Fig. 2.—"Teco" Style "D" Union Conduit Fitting.

Fig. 2 shows the style "D" Union conduit fitting. This fitting is made for one-half-inch, three-quarters-inch, one-inch, one-and-one-quarter-inch, one-and-one-half-inch, two-inch, two-and-one-half-inch and three-inch conduit, for two, three and four wires, and with blank bushings and locknuts. The one-half-inch and three-quarters-inch fittings have composition bushings in the head for wire outlets. The one-and-one-quarter-inch fittings have porcelain bushings with one-half-inch holes. The one-and-one-half-inch and two-inch fittings have porcelain bushings with seven-eighths-inch holes. The two-and-one-half-inch and three-inch fittings have one-and-one-half-inch bushings.

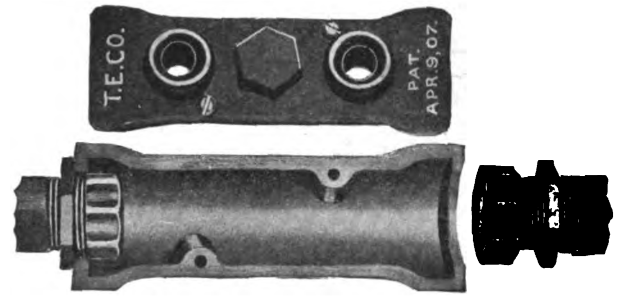

Fig. 3.—"Teco" Style "A" Union Rigid and Flexible Conduit Fitting.

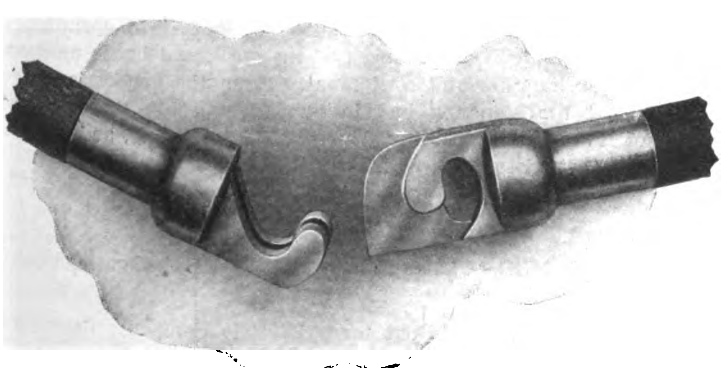
Fig. 3 shows the style "A" Union rigid and flexible conduit fitting. This is made to accommodate one-half-inch and three-quarters-inch conduits, and is fitted with adjustable covers for one, two and three-wire circuits.

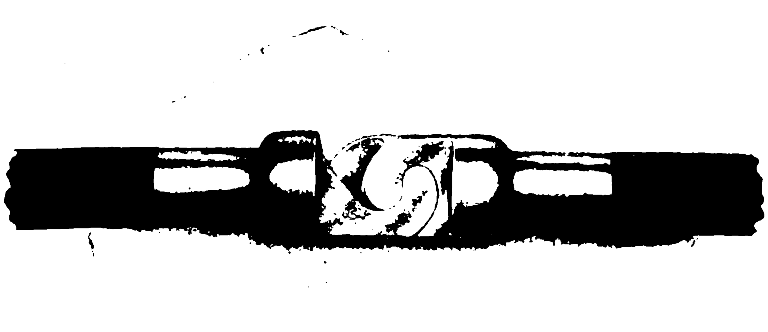
These conduit fittings are especially adapted for open construction, and the style "A" fitting is interchangeable with a "T" or an "X," which makes it an easy matter to add to a line after the work has been finished up.

The Chicago Conduit Rod Coupling.

The accompanying illustrations show the conduit rod coupling which has been placed on the market by the Chicago Conduit Rod Coupling Company, 310 Cuyler avenue, Chicago, Ill. The function of this coupling can be readily understood from the illustrations. The tongue which enters the groove in the other portion of the joint fits tightly against the butt of that casting, preventing end play. It also prevents lost motion in twisting, as there is just enough side play to permit the rods to be used in pipe laid with slight irregularities and changes of direction. The conduit heads are made of malleable cast iron. The thickest part of the casting is at the precise point where the greatest strain occurs. The coupling is so designed that four-foot rods may be connected and disconnected with perfect ease in the smaller manholes. Double rivet holes are provided, giving great pulling strength and also high twisting strain. The tongue is pierced, permitting the attachment of a pulling cable and also facilitating the cleaning of the joint if this should become necessary.



Chicago Conduit Rod Coupling, Disassembled.



Chicago Conduit Rod Coupling.

Alternating Current in New York City.

The United Electric Light and Power Company, New York city, has closed a contract with the Astor estate covering the complete supply of electricity for lighting to a new office building to be erected on Seventh avenue, extending from Forty-third to Forty-fourth street, opposite the New York Theatre. Thirty-four stores will be included in this building. Elevators and pumps will also be supplied with alternating current.

The Hedden Construction Company has placed an order for sixteen hoisting machines to be operated by two-phase alternating-current motors. These hoists will be the first used on the new office building to be erected on the site of the Fifth Avenue Hotel. The current will be supplied from the mains of the United Electric Light and Power Company. Over 800 horse-power in hoists will be used during the construction of this building.

Current Electrical News

DOMESTIC AND EXPORT.

TO GENERATE ELECTRICITY IN WEST VIRGINIA GAS FIELDS—It is understood that a company, to be capitalized at $3,500,000, is being formed to generate electricity at gas fields in West Virginia, to be transmitted to Cincinnati, Ohio. The directors of the Columbia Gas and Electric Company, Cleveland, Ohio, which owns large gas fields in West Virginia, are said to be interested in this enterprise.

TO TEST STATE'S WATER RIGHT—Interests using hydraulic power on the Oswego River at Fulton, Oswego County, New York state, have filed against the state claims aggregating $1,043,940. The state, it appears, has appropriated the water at that point for the new barge canal. The character of the damage is similar to that involved in a claim of the Fulton Light, Heat and Power Company for $3,000,000, which is now pending before the State Court of Claims.

ECONOMIC POWER AND CONSTRUCTION COMPANY GETS TEMPORARY INJUNCTION—Supreme Court Justice George H. Fitts, of Albany, N. Y., has granted a writ of prohibition to the Economic Power and Construction Company, restraining the Public Service Commission until September 28 from holding a hearing on the company's right to operate in Geneva, N. Y. The Economic company claims to have a general franchise in the state granted to it prior to the existing franchise laws and commissions created by the legislature. The company proposes to supply steam heat and electric power to Buffalo citizens as soon as suits now pending in the courts have been disposed of.

TO CONSOLIDATE LIGHTING PLANTS—Plans are maturing, it is reported, for the consolidation by H. E. Huntington and associates of all the power and lighting companies in Los Angeles, Cal., with $50,000,000 capital stock. On September 1 the plant of the City Gas Company, purchased recently by Huntington's Pacific Light and Power Company, will be formally turned over, and the next intended step, it is asserted, is the purchase of the Los Angeles Gas and Electric Company, on which a price of $7,000,000 with a bond issue of $3,500,000 is said to have been set. No figures have been given out regarding the Edison Electric, the largest of all the companies, but it is believed that it is included in the project.

NEW ELECTRIC ROAD—Work is to begin at once near Fredericksburg, Va., on a dam across the Rappahannock River. The work is to be under the direction of W. C. Whitner, hydraulic engineer for the Virginia Passenger and Power Company, who is also president of the Fredericksburg Power Company. Both these companies are controlled by the Gould interests. The Goulds last year succeeded in obtaining a repeal of the law prohibiting a paralleling of the Richmond, Fredericksburg & Potomac Railroad, and announced their intention of building an electric line from Richmond, Va., to Washington, D. C. Application for a charter with this object in view was made, but it was withdrawn, and a charter will be asked for a line to connect with the Richmond & Chesapeake Bay line at Ashland and an electric line which comes from Washington into Virginia and which line is owned by the Goulds. Power developed by the building of the new dam near Fredericksburg will be used to operate the cars on the new line. The dam will involve an expenditure of $50,000, will be of concrete, 800 feet long, twenty-five feet high and will be completed by Christmas. The power to be developed will reach about 12,000 horse-power.

NEW WESTERN ELECTRIC LINE—M. D. Wright, a capitalist of Cœur d'Alene, Idaho, has authorized the announcement that work on an electric railway between Cœur d'Alene and Wallace, ninety-five miles, will begin within four months. The new road will be a branch of the Spokane & Inland Empire Railway system, and will be under its control. The system already operates a line between Spokane and Cœur d'Alene and Hayden Lake. Mr. Wright added: "There is no doubt that the long-talked-of line between Cœur d'Alene and Wallace will be built, and the Hayden Lake line will be built as far as Squaw Bay on Pend Oreille Lake. A junction of the two roads will be at Cœur d'Alene. The Wallace line will follow the Blue Creek route to Catalbo, and from there it will parallel the Oregon Railroad and Navigation line to Wallace. It will almost follow the Washington Water Power high-tension line. The grade will be much better than the Fourth of July Cañon route, there being few and short tunnels, if any. The grade will be about one per cent." Announcement is also made by Jay P. Graves, president of the system, that his company and associates are planning an electric line from Nine Mile Bridge to Miles, thence to Kettle Falls, Wash., 145 miles. This will afford an outlet to Spokane for immense mineral tonnage from the properties along the Columbia River, as well as in the interior of the Colville reservation.

ROCHESTER, CORNING & ELMIRA TRACTION COMPANY—The Public Service Commission for the Second District of New York state has issued a supplemental order in the case of the Rochester, Corning & Elmira Traction Company, providing that the company can issue capital stock to the amount of $380,000, par value, and bonds, par value, to the amount of $1,000,000. The new order is made upon the condition that none of the proceeds of the stock or bonds be used for contingencies, legal or other expenses, organization expenses or working capital, the proceeds of the stock and bonds to be used exclusively for the construction and equipment of that part of the road from Rochester to Conesus Lake; and that any excess above such requirements shall be held until further order from the commission, but no bonds shall be issued or sold until stock to the aggregate amount, par value, of $380,000 shall have been subscribed for by responsible parties, such subscription to be approved to the satisfaction of the commission. The original application asked for an authorization for the issuing of bonds to the amount of $8,000,000 and of the balance of its stock, $3,880,000. The company had previously issued $120,000 capital stock. The order allowed an issue of $4,210,000 in bonds and the full issue of $4,000,000 in stock, a total capitalization of $8,210,000. The commission required as a condition of the order that the $4,000,000 of capital stock must be subscribed by responsible parties before any bonds could be issued. The projectors of the company reported that it was impossible to dispose of the stock and bonds necessary for the construction and completion of the road, but stated that if the company were permitted to construct first that part of its road extending from Rochester to Conesus Lake, a distance of twenty-five miles, and equip and put it in operation, it would be able to sell and dispose of the stock and bonds necessary for such construction and equipment. From the application it appeared that the company had in hand $120,000 in cash, the proceeds of its capital stock issued prior to July 1, 1907, and that the estimated cost of twenty-five miles of road would be $1,350,000.

NEW INCORPORATIONS.

DICKENS, NEB.—North Platte & Dickens Telephone Company. $5,005.

HARRISBURG, PA.—Boyertown Electric Company, Boyertown. $5,000.

DOVER, DEL.—Electrical Corporation Consolidated Company, Wilmington. $1,500,000.

MADISON, WIS.—Farmers' Mutual Telephone Company, Baraboo. An amendment increasing its capital from $6,000 to $12,000.

SALEM, ORE.—Gordon Falls Electric and Manufacturing Company, Portland. $225,000. Incorporators: Charles Coopey, George L. Peaslee and E. Y. Judd.

MILWAUKEE, WIS.—The Home Telephone Company, Durand. $12,000. Incorporators: W. E. Plummer, George Tarrant, A. J. Wallace and Frank Pierce.

ELECTRIC RAILWAYS.

MILWAUKEE, WIS.—The Milwaukee Electric Railway and Light Company has inaugurated hourly service between Milwaukee and Watertown.

DENVER, COL.—The electric service to Eldorado Springs from this city and Boulder has been opened. This completes the entire Denver & Interurban system.

ASHEVILLE, N. C.—Actual work has been begun on the Weaverville Electric Railway, which is to extend from New Bridge Station, on the Rapid Transit Railway, four miles to Weaverville.

CANON CITY, COL.—President S. H. Atwater, of the Kansas & Colorado Railroad Company, has signed contracts for the surveying and grading of the Cañon City division, and work has been begun.

NIAGARA FALLS, N. Y.—The International Railway Company will begin at once the work of extending its Devil's Hole line to the tracks of the Rome, Watertown & Ogdensburg Railroad just below Niagara University.

PORTLAND, ME.—The directors of the Portland & Northern Railroad Company, which contemplates the operation of an electric line from Portland to Bridgton, went over the proposed route of the road recently and made arrangements for the survey.

MEADVILLE, PA.—In the offices of the register and recorder in this city there has been filed a mortgage of $300,000 against the Erie & Cambridge Springs Street Railway Company in favor of A. L. Curtze, trustee, to secure an issue of five per cent gold bonds.

OAKLAND, CAL.—The board of supervisors has decided provisionally to grant permission to A. W. Maltby and Joseph Naphtaly to operate an electric street railway through the Alameda County part of the Alameda-Contra Costa tunnel, back of Claremont. The franchise is limited to five years.

IOLA, KAN.—A deal has been closed whereby the Iola Electric Railway Company, now running cars between Iola and LaHarpe, comes into possession of the Kansas Southern Electric Railway Company, which will build an electric line between this city and Pittsburg, Kan., touching all important cities.

McKINNEY, TEX.—E. M. Hopkins and associates, of Detroit, Mich., who have held several conferences with citizens along the line of the proposed Fort Worth-Bonham Interurban, finding that their proposition would not be accepted by the local citizens, have purchased the right of way of the old proposed line from here to Bonham.

MORGANTOWN, W. VA.—At a meeting of the directors of the Morgantown & Dunkard Valley Electric Railway, held at Blackville, it was decided to start the work of building the first section of the road. This is to be constructed from Granville to Stumptown to the mouth of Wade's Run. J. A. Martin has been selected to superintend the construction of the road.

BILLINGS, MONT.—The survey for the proposed electric line from Columbus to Cooke City has been completed between the former city and Absarokee, and right-of-way men are making arrangements to secure right of way for the road from Absarokee to Cooke City, a free right of way having been assured between Columbus and Absarokee. The city of Columbus has also donated terminal land and raised sufficient to build a bridge across the Yellowstone.

BUTLER, PA.—Butler and Pittsburg capitalists recently went over the route of the proposed new trolley line from Butler to Greenville by way of Queens Junction, Slippery Rock, Grove City and Mercer, and announcement is made that the right of way will be obtained this fall. Two routes are now being considered. The route favored follows the Bessemer & Lake Erie Railroad to Kiester Station and then west to Slippery Rock. The road to Greenville would cost $3,000,000.

PITTSBURG, PA.—Contracts have been awarded for the connection of the Youngstown & Ohio River Railway with the Ohio Valley Scenic route at East Liverpool. Four miles of track will have to be constructed, from East Liverpool north to a point between East Liverpool and West Point. The Youngstown & Ohio River electric road is arranging to haul coal from a large undeveloped field in the vicinity of West Point to make shipping connection with the Erie Railroad at Lisbon.

MEMPHIS, TENN.—Contract for the construction of the first section of the interurban system between Memphis and Lake View, Miss., has been let by the board of directors of the Lake View Traction Company to M. J. Roach. The total cost of the Lake View division, about twelve miles, excluding the electrical equipment and rolling stock, will be about $189,000. The contract calls for the completion of the railroad and track laying on this division by January 1, 1909. Next summer, it is expected, will see the system in active operation.

JANESVILLE, WIS.—Organization of the Cincinnati Construction Company has been completed with the election of H. H. Zigler, Columbus, as president; W. L. Jamison, vice-president; F. D. Jamison, Cincinnati, secretary and treasurer; Joseph Ellis, Janesville, resident manager and assistant secretary. The officers and George P. Stimson, of Cincinnati, constitute the board of directors. Janesville was designated as the headquarters. Behind the company is a syndicate of Ohio capitalists which has built several roads in Michigan. H. H. Zigler, the president, says that he hopes to have the survey complete, the profiles ready and everything ready for application to the State Railway Commission for a franchise by October 1. Then, if the winter is an open one, work of construction on the line to Madison will begin at once.

KANSAS CITY, KAN.—Plans are being perfected for the organization of a trust company in Kansas City. It will be known as the Kansas City Union Trust Company, and the purpose is to finance a system of interurban trolley lines out of Kansas City. The company that is first to build these lines is known as the Interstate Power and Transit Company. The road will run through Topeka and Lawrence, with a road to Coffeyville, through Garnett, Iola, Humboldt and Cherryvale, with branch lines to Parsons and Independence. Later it is proposed to extend the line from Coffeyville to Oklahoma City by way of Tulsa, with spurs to Guthrie, Shawnee and Muskogee. Another proposed extension is from Topeka to Salina and Hutchinson. It is also proposed to build from Parsons to Joplin.

ST. CATHARINE'S, ONTARIO—The projected electric railway across the Niagara peninsula from Dunnville appears to be a practical undertaking. The scheme was introduced some months ago, but fell through even after municipal by-laws had been passed to purchase a $39,000 bond issue to aid the promoters. The president of the company, James A. Ross, of Wellandport, the provincial member, has been working out the new scheme and has enlisted the aid of George Dunstan, of Toronto, and P. T. McGrath, of Worcester, Mass. It is now proposed to build from Dunnville through Wellandport and St. Ann's to Beamsville, where a connection would be made with the Hamilton, Grimsby & Beamsville line. A party of surveyors is now at work. The Dunnville people will not be called upon to finance the bonds, but will be asked for the right of way through certain streets. The proposed road would open up a large section which is now practically shut off from quick communication with the more northerly and easterly end of the district.

BUFFALO, N. Y.—The Public Service Commission for the Second District has given its consent to the Niagara Falls Electrical Transmission Company to grant and transfer to the Buffalo, Lockport & Rochester Railway Company private rights of way for its transmission line in the villages of Middleport, Medina, Albion, Brockport and Spencerport and towns of Greece, Gates, Ogden and Ridgeway, which lie between the city of Lockport and the city of Rochester along the right of way of the railway company, and to the Buffalo, Lockport & Rochester Railway Company to take and hold the same. The Niagara Falls Electrical Company is also permitted to assign and transfer to the Buffalo, Lockport & Rochester Railway Company the municipal consents or franchises of the localities mentioned above. The Buffalo, Lockport & Rochester Railway Company is authorized to take, hold and exercise all the rights conferred or created by these consents. The Buffalo, Lockport & Rochester Railway Company is authorized to use the transmission line constructed by it from South Greece station in the county of Monroe to the substation in the village of Albion, county of Orleans, in and about the operating of its railroads.

ELECTRIC LIGHTING.

TAUNTON, MASS.—The committee on street lights has voted to extend the incandescent lighting system at a cost of about $8,000.

LANDER, WYO.—It is announced that Asmus Boysen, of Chicago, will build another power plant in the cañon of the Pope Agie, above Lander.

PEMBROKE, ME.—The plant of the Pembroke Power Company, which was destroyed by fire last spring, will be rebuilt, work to start at an early date.

STRASBURG, VA.—The Rock Spring Electric Company, incorporated with $25,000 capital, will establish an electric plant and has contracted for machinery.

ALBANY, N. Y.—The Albany Electric Illuminating Company has contracted for the purchase and installation of new street lamps in this city. The amount of the contract is $59,000.

GEORGETOWN, PA.—The township commissioners have awarded a street lighting contract to the Prospect Rock Light, Heat and Power Company. There will be twenty-five arc lamps installed.

SUTTON, MASS.—The Grafton Electric Company has been awarded the contract for street lighting. This calls for sixty-five incandescent lamps at a cost of $14 per year, the contract to run for five years.

WEST CALDWELL, N. J.—The West Caldwell borough council has decided to extend its lighted territory and authorized the lighting committee to execute a contract with the Public Service Corporation to install additional lamps.

MEDFORD, ORE.—Colonel F. H. Ray, of New York, president of the Rogue River Electric Company, formerly the Condor Water and Power Company, on a recent trip West, gave final orders for the enlarging of the plant which is now furnishing electric power to southern Oregon towns.

CLINTON, MASS.—The town of Leominster is said to be considering the feasibility of securing electricity for municipal lighting from the Connecticut River Power Company, and as a part of that scheme the purchase of the Leominster Electric Light and Power Company's plant.

COLORADO SPRINGS, COL.—By an arrangement concluded recently between the United Hydroelectric Company, of Georgetown, and the Central Colorado Power Company, of this city, the former company has been made the sole distributing agent in Gilpin and Clear Creek counties for the latter company.

FREMONT, OHIO—The Fremont Power and Light Company, recently granted a franchise by the city council, has accepted the terms of the grant and announces that work on the new plant will begin at once. The company proposes to harness the Sandusky River and erect a large power plant in Ballville, south of Fremont.

NEWARK, N. J.—The municipal lighting committee has asked the finance committee for $10,000 for preliminary plans for building a municipal lighting plant. The scheme was voted on favorably at the 1907 election, and calls for an expenditure of $1,000,000. The $10,000 is to pay an expert for making estimates and drafting plans.

SHELBURNE FALLS, MASS.—The Shelburne Falls Electric Light and Power Company has purchased of the Lamson & Goodnow Company the strip of land south of the W. C. Thompson Block, and is planning to build a new power station. The company will go ahead with the work at once, and when completed will give both day and night service.

GROTON, VT.—Clark & Davidson, owners of the grist mill at this place, are to put in an electric light and power plant, to supply power to the stone sheds and electricity for street and house lighting. The firm has purchased the old Baldwin mill water rights located at the lower end of the village, and the work of replacing the dam washed out several years ago has commenced. It is expected to have the plant in operation by October 1.

HAGERSTOWN, MD.—The Antietam Electric Light and Power Company, composed of Clarence E. Easterday, Orville E. Shifler and Harry L. Moser, has purchased of John W. Nihiser a portion of the Delemere tract, along the Antietam Creek, for $4,250. The property is valuable by reason of the water power, a large milldam built in the creek being part of the property. The buyers, who recently obtained a contract to light Boonsboro for ten years, will build a power plant at the old Delemere Mill.

PITTSFIELD, ME.—Work will be begun shortly on the building of a 200-foot log dam with concrete bottom at Cleveland Rips in North Anson, on the Carrabasset River, by the Franklin Power Company, chartered in 1903 under the name of the Carratunk Power Company, capitalized at $100,000, to provide Farmington, New Vineyard and ultimately the town of Wilton with electricity for illuminating and manufacturing purposes. It is expected that by October lights will be in operation in Farmington.

OLYMPIA, WASH.—Papers for what is thought to be a rival company to the Skookumchuck Power Company have been filed with the county commissioners by H. P. Schiel and William McArthur. The new company will get power in the Deschutes near Rânier and furnish power in the vicinity of Ranier, Bucoda and Tenino. The Skookumchuck Power Company will get its power about fourteen miles above Tenino in the Skookumchuck. Both companies state work will commence immediately when franchises are granted.

LEGAL NOTES.

RIGHT TO DISTURB WIRES OF STREET RAILWAY SYSTEM—The right to move a building along a public street upon which an electric railway has been lawfully constructed, to the serious interference with the operation of the cars and the wires by which they are operated, is denied in Fort Madison Street Railway Company *vs.* Hughes (Iowa), 114 N. W. 10, 14 L. R. A. (N. S.) 448.

RIGHT TO REMOVE TELEPHONE POLE—The right of the owner of a leasehold renewable forever, which extends to the centre of a private alley, to cut down and remove a telephone pole placed on his half thereof without permission in such a manner as to interfere with his reasonable use of the alley, after giving notice to its owner to remove it, which is not acted upon within a reasonable time, is sustained in Maryland Telephone and Telegraph Company *vs.* Ruth (Md.) 68 Atl. 358, 14 L. R. A. (N. S.) 427.

RIGHT OF CITY TO FIX ADDITIONAL BURDENS UPON TELEPHONE COMPANY—A city which, by ordinance, has permitted a telephone company to erect its poles and wires in the streets, and has thereby invited the company to make investments and expenditures, which it has made in good faith and in reliance on the ordinance, is held, in Plattsmouth *vs.* Nebraska Telephone Company (Neb.), 114 N. W. 588, 14 L. R. A. (N. S.) 654, to have no right arbitrarily to impose by subsequent regulations, without necessity or the demands of public convenience, additional burdens upon the company which are clearly beyond the reasonable exercise of the police power.

RIGHT OF INTERURBAN ELECTRIC RAILWAY COMPANY TO USE OF CITY STREETS—An interurban electric railway company using tracks in a city street for street-car business under a street-railway franchise is held, in Brickles *vs.* Milwaukee Light, Heat and Traction Company (Wis.), 114 N. W. 810, 14 L. R. A. (N. S.) 644, not to take the interest of abutting owners for interurban purposes until it transforms the tracks, roadbed and appliances to interurban uses; neither the passage of a statute authorizing condemnation, nor the continued wrongful use for interurban purposes of the street railway tracks thereafter, being considered an expropriation of their rights.

PRELIMINARY INJUNCTION GRANTED ON ALLEGED TRANSFORMER INFRINGEMENT—Judge Ray, of the United States Circuit Court for the Northern District of New York, has granted a preliminary injunction against the Middleburg & Schoharie Light, Heat and Power Company, in the suit of the Westinghouse Electric and Manufacturing Company against the Middleburg company for infringement of the Stanley patent, No. 469,809. The Middleburg company uses the transformer manufactured by the Pittsburg Transformer Company. The operation of the injunction is suspended until November 15 to permit the Middleburg company to either remove the infringing transformers or to appeal.

PERSONAL MENTION.

MR. A. A. ARLINE, of Dallas, Tex., has been appointed manager of the Orange, Tex., office of the Southwestern Telegraph and Telephone Company.

MR. H. A. EVERETT has resigned as president and director of the Toledo Railways and Light Company. Barton Smith takes his place as director, but the office of president remains unfilled.

MR. J. J. BROOMFIELD, manager of the contract department of the Interstate Telephone Company, has resigned and will be succeeded by F. B. Shalters, who has assumed charge of the Trenton, N. J., office.

MR. CLAUD HAUGH, for ten years inspector of the Waynesboro, Pa., exchange of the Bell Telephone Company of Pennsylvania, has resigned and will devote his attention to the electrical contracting business which he recently established.

MR. W. V. N. POWELSON, it is announced, has resigned as president of the Union Electric Light and Power Company, of St. Louis, Mo., and will be succeeded by Arthur Williams, of New York. Mr. Powelson will engage in engineering, establishing a company in New York to be known as Cooper & Powelson.

DR. WILLIAM M. HABIRSHAW, president of the Habirshaw Wire Company, of Yonkers, N. Y., a widely known man in the electrical field, and one of the most skilful analytical chemists in the country, is very ill at Saratoga, N. Y., his summer residence. Dr. Habirshaw has been an invalid for several years and recently suffered a relapse, from which it is hardly expected he can recover.

MR. D. S. DRAKE, local manager for the Bell Telephone Company at Huntingdon, Lewistown and Saxton, Pa., has resigned to accept a position with the Raystown Water Power Company. Mr. Drake had been with the telephone company for many years and established the Lewistown exchange in 1883. H. E. Provost, of Scranton, succeeds Mr. Drake. The position has been changed, however, to that of contract agent for the three exchanges named.

DR. NEVIL MONROE HOPKINS, assistant professor of electrical engineering at George Washington University, and chief electrical engineer for the United States Navy Department in the consolidation of navy yard power plants, is the author of an entrancing story entitled "The Investigation at Holman Square," which is one of the leading features of the September issue of *Lippincott's Magazine*. Dr. Hopkins is the author of several other detective stories.

NEW MANUFACTURING COMPANIES.

PORTLAND, ORE.—The Columbia Electrical Engineering Company has been incorporated with a capital of $5,000. The incorporators are J. E. Kilkenny, George L. Epps and J. F. Kendricks.

CAMDEN, N. J.—The General Waves Power Company has been incorporated with a capital of $200,000 to act as mechanical and electrical engineer. The incorporators are E. E. McWhiney, G. E. Holmes and F. A. Kuntz, of Camden.

BOSTON, MASS.—The United States Apparatus and Instrument Company, of Fall River, has been incorporated with a capital of $10,000, to deal in electrical and medical apparatus. The directors are: Louis Foster, Boston, president and treasurer; William J. Jones and M. Doherty.

SALT LAKE CITY, UTAH—Articles of incorporation of the Ogden Electric Supply Company have been filed with the county clerk. The concern has a capital stock of $10,000 divided into $1 shares and is incorporated for a period of fifty years. The officers are: President, Charles A. Halverson; vice-president, George Halverson; secretary-treasurer, Lawrence Herdti. These, with O. W. Halverson and Arthur Halverson, compose the board of directors.

GREAT FALLS, MONT.—Articles of incorporation for the Evans Engineering Company have been filed in the office of the county clerk and recorder by the incorporators, Thomas Evans, John Olds, Alfred F. Evans and Fred W. Sewell, all of Great Falls. The company will engage in the manufacture, installing and selling of engines, electrical apparatus and machinery. The capital stock of the concern is set at $35,000, divided into shares of a par value of $10 each. The largest portion of the stock is in the hands of Thomas Evans, who holds 238 shares, the other members holding 114 shares each. Five thousand eight hundred dollars has been subscribed.

ELECTRICAL SECURITIES.

There is very little to say concerning stock market developments, except to reiterate the statements which have been made for the past three or four weeks. In the face of rather slow general improvement in business, prices continue to rise, until it is feared that the present values have over-discounted a considerable gain in the near future. The factors making for the present rise appear to be the great ease with which time loans can be obtained, the indications of a bounteous harvest of every nature of agricultural product, the splendid condition of the freight railroads for handling large quantities of freight at a minimum expense, and the forecast of a continuation of the present form of government for at least the next four years.

ELECTRICAL SECURITIES FOR THE WEEK ENDED AUGUST 8.

New York:	*Closing.*
Allis-Chalmers common	11⅜
Allis-Chalmers preferred	34¾
Brooklyn Rapid Transit	55⅝
Consolidated Gas	139
General Electric	146
Interborough-Metropolitan common	12¼
Interborough-Metropolitan preferred	35⅛
Kings County Electric	122
Mackay Companies (Postal Telegraph and Cables) common	66½
Mackay Companies (Postal Telegraph and Cables) preferred	66½
Manhattan Elevated	138
Metropolitan Street Railway	31
New York & New Jersey Telephone	110
Western Union	57
Westinghouse Manufacturing Company	76

The directors of the Kings County Electric Light and Power Company have declared the regular quarterly dividend of 2 per cent, payable September 1. The books close August 21 and open September 1.

Boston:	*Closing.*
American Telephone and Telegraph	122
Edison Electric Illuminating	—
Massachusetts Electric	47
New England Telephone	112½
Western Telephone and Telegraph preferred	68
Philadelphia:	*Closing.*
Electric Company of America	10
Electric Storage Battery common	39
Electric Storage Battery preferred	39
Philadelphia Electric	9⅞
Philadelphia Rapid Transit	14⅜
United Gas Improvement	88¼
Chicago:	*Closing.*
Chicago Telephone	—
Commonwealth Edison	—
Metropolitan Elevated preferred	45
National Carbon common	68
National Carbon preferred	108

The Oak Park Elevated's daily average of passengers carried, including transfers, for July, was 40,467, a decrease of 3,241. The daily average of passengers carried for July by the Metropolitan Elevated was 131,152, a decrease of 4,627, and by the South Side Elevated 114,362, an increase of 2,429.

DATES AHEAD.

Michigan Electric Association. Annual meeting, Grand Rapids, Mich., August 18-21.

International Association of Municipal Electricians. Annual convention, Detroit, Mich., August 19-21.

Ohio Electric Light Association. Annual convention, Put-in-Bay, Ohio, August 25-27.

Colorado Electric Light, Power and Railway Association, Glenwood Springs, Col., September 16-18.

Arkansas Association of Public Utilities Operators. First annual convention, Little Rock, Ark., September 17-18.

Old Time Telegraphers' and Historical Association, and Reunion of Military Telegraphers, Niagara Falls, N. Y., September 16-18.

Illuminating Engineering Society. Annual convention, Philadelphia, Pa., October 6-7.

American Street and Interurban Railway Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Accountants' Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Claim Agents' Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Engineering Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Manufacturers' Association. Annual convention, Atlantic City, N. J., October 12-16.

American Electrochemical Society. Fall meeting, New York city, October 30-31.

TELEPHONE AND TELEGRAPH.

PLACERVILLE, CAL.—It is announced that an extension of the Pacific Telephone and Telegraph Company's line from this city to Lake Tahoe will be undertaken at an early date.

NORWOOD, MASS.—The New England Telephone and Telegraph Company has changed its system from the magneto to the common battery type, and moved into new quarters.

MILES CITY, MONT.—The Rocky Mountain Bell Telephone Company is making preparations for the installation of a telephone system in Miles City, with headquarters in the Miles Building.

ANACONDA, MONT.—Work is progressing rapidly on the Independent Telephone Company's line between Butte and Anaconda, and the company expects to be ready for business in the early fall.

HOUSTON, TEX.—The Southwestern Telegraph and Telephone Company is making a number of improvements to its system in the South End. Later it is intended to establish an exchange in that portion of the city.

ALTURAS, CAL.—The Western Pacific Telephone and Telegraph Company has been incorporated for the purpose of connecting all the towns of Modoc, Lassen and Plumas counties, work to be commenced in the near future.

MILWAUKEE, WIS.—The underground telephone system between Milwaukee and Racine, the first division of the proposed system between this city and Chicago, has been formally opened. The system is now open for general business.

ATLANTA, GA.—The Southern Bell Telephone and Telegraph Company has purchased the Covington Telephone Company, of Covington, Ga., and the two systems will be consolidated as rapidly as the physical work can be accomplished.

MEREDITH, N. H.—At the annual meeting of the Meredith Telephone Company the following officers were elected: President, B. Blaisdell; vice-president, F. W. Storey; clerk, P. A. Ellsworth; treasurer, E. S. Wilard; manager, P. A. Ellsworth; auditors, E. W. Longley; directors, B. Blaisdell, J. F. Beede, B. R. Dearborn, Edmund Page. A dividend of $1.50 per share was declared, payable August 15.

COLUMBUS, OHIO—The Farmers' Independent Telephone Company of Canal Winchester has been incorporated with a capital stock of $25,000. The line is to connect Canal Winchester, Columbus and Lancaster at present, and will extend through the counties of Fairfield, Pickaway and Franklin. The incorporators are McC. Martens, Thomas J. Barr, Thurman T. Courtright, W. F. O'Gara and R. C. M. Hastings.

WATERVILLE, ME.—The Kennebec Farm and City Telephone Company has completed its line from Norridgewock to Oakland village by way of the Ten Lots. All the towns up the Somerset Railway may be reached as far as The Forks, including Norridgewock, Madison, North Anson, Solon, Bingham, Caratunk, Athens, Starks, Mercer, Canaan and Skowhegan. The whole system includes about 800 telephones.

PAVILION, N. Y.—The Pavilion Telephone Company, which was incorporated under the laws of the state, in Albany, a few weeks ago, with a capital of $10,000, is actively at work. It already has available for use about fifteen miles of poles and wires, the property of the Inter-Ocean Telephone Company. The directors are D. C. Higgins, S. O. Hubbard, M. A. Christman, David Morrow, Earl Starr, Horace Bradley and Dean Hudson. The officers are: President, Horace Bradley; vice-president, Earl Starr; secretary and treasurer, D. C. Higgins. There are about 200 subscribers. The company expects to have its lines ready for service in thirty days.

PORTLAND, ORE.—Extensions and betterment of the service are the purposes behind the plan of reorganization that has been adopted by the directors of the Pacific Telephone and Telegraph Company. This includes the redistricting of the company's telephone system into three districts. The southern division will extend from the Mexican line to San Luis Obispo, the central division from San Luis Obispo to the Oregon line, while the third, or northern district, will embrace the states of Oregon, Washington and Idaho. Under the plan of reorganization each of the three districts will have practically a system of its own, with its own respective corps of officers. W. J. Phillips, who for years has been superintendent of the home or central division, with headquarters at San Francisco, has been transferred and will be the superintendent of the northern division.

LUDINGTON, MICH.—The United Telephone Company of Michigan has been organized here with $200,000 capital and with several local capitalists interested. It will take over the property of the Lake Shore Telephone Company now operating in Mason and Oceana counties. The general offices of the latter company will be moved from Hart to Ludington and become the office of the new company. Thomas Bromley, Jr., of Hart, will be the general manager of the company. The officers are as follows: President, W. A. Cartier, Ludington; vice-president, Gardner Sands, Pentwater; secretary and treasurer, Thomas Bromley, Jr.; attorney, A. E. Keiser. C. H. Hood, of Detroit, who has been interested in the organization of the new company, says that $78,000 will be spent in reconstructing the present county service, bringing it up to date, and that a model telephone building will be erected in Ludington.

NEW PUBLICATIONS.

NEW YORK STATE PUBLIC SERVICE COMMISSION, SECOND DISTRICT—The Public Service Commission of the State of New York, Second District, has published circular No. 38, effective August 1, 1908, giving the regulations prescribing the form and governing the construction and filing of freight tariffs and classifications and passenger fare schedules of railroad corporations, and general regulations and rulings. The commission has also published its opinion in the matter of the application of the Elmira, Corning & Waverly Railway, submitted July 9 and decided July 23.

"ON THE CANAL ZONE"—Thomas G. Grier, of Chicago, Ill., well known in the electrical field, is the author of a very interesting descriptive work entitled "On the Canal Zone." During a trip which Mr. Grier recently made to the Isthmus of Panama he took copious notes and a great many photographs. The present volume is the result of this trip. The work is interesting, as it gives a first-hand impression of this remarkable enterprise. While it is not electrical in any way, Mr. Grier has incorporated a minute description of whatever use has been found on the isthmus for electricity either for illumination or power. The book is from the press of the Wagner & Hanson Company, Chicago, Ill., and is dedicated to the memory of Mr. Grier's father, John Alexander Grier, formerly chief engineer in the United States Navy, who spent several years cruising in southern waters.

INDUSTRIAL ITEMS.

THE SACHS COMPANY, Hartford, Ct., will be pleased to send to any one interested upon request its bulletin devoted to electrical protective devices for any voltage.

THE H. T. PAISTE COMPANY, Philadelphia, Pa., in bulletin No. 57 devotes considerable space to a description and price list of the Paiste ground clamp and a blackboard talk on Paiste molding crossovers.

THE METROPOLITAN ELECTRICAL SUPPLY COMPANY, Chicago, Ill., has been appointed agent for the Crescent Insulated Wire and Cable Company, of Trenton, N. J. The Metropolitan company will carry a large stock of this well-known company's product, enabling it to fill orders from Chicago promptly.

THE TRUMBULL ELECTRIC MANUFACTURING COMPANY, Plainville, Ct., in the August issue of "Trumbull Cheer," describes the Trumbull "Kappa" switch with high fingers. There is also an illustration of a very interesting special switchboard mounted in an iron box. The Trumbull switchboards are made to any specification.

THE CENTRAL ELECTRIC COMPANY, Chicago, Ill., is distributing a revised price list on "Raven Core" rubber-covered wires and cables. This price list, which includes all classes of wire and lamp cord, will be mailed upon request. The company will also be pleased to furnish revised price lists on Columbia incandescent lamps of the Gem, Gem Prismo, tungsten and tantalum types.

THE TUNGSTOLIER COMPANY, 519-521 Citizens Building, Cleveland, Ohio, is preparing some very interesting literature devoted to Tungstolier lighting fixtures. This line comprises an absolutely new design of lighting fixtures, especially developed for use with tungsten lamps. The range of styles is wide enough to afford a selection which will fit in with any requirements. Full information may be secured from the company upon request.

THE CUTTER COMPANY, Philadelphia, Pa., is announcing a competition for twenty-five essays on the use of circuit-breakers. Prizes to the amount of $1,200 will be distributed to the writers of the best essays, and the competition is open to every user of electricity who is acquainted with the I-T-E circuit-breaker and its wide field of usefulness. The conditions of this competition will be mailed on receipt of request addressed "Essay Competition," The Cutter Company, Philadelphia, Pa.

THE NERNST LAMP COMPANY, Pittsburg, Pa., announces that H. H. Sturtevant, of Zanesville, Ohio, proprietor of the largest department store in southeastern Ohio, has placed an order with the Ohio Electric Railway Company for a complete installation of Westinghouse-Nernst lamps, to replace electric arc lamps. This was at once the first order for the new Westinghouse-Nernst units to be placed in the Cincinnati territory of the Nernst Lamp Company, and the first fruits of the new business-getting campaign of the Ohio Electric Railway Company.

THE H. W. JOHNS-MANVILLE COMPANY, 100 William street, New York city, has ready for distribution literature describing the "Point-Tite" roof cement for tinners' and slaters' use, and the "J-M" roof coating, which is made primarily of pure asphalt dissolved in pure linseed oil. This coating is suitable for all kinds of roofing work, metal work, and wherever protection from the elements is required. One gallon will cover 100 square feet. Another leaflet which the company is distributing is devoted to the advantages of a "Built-Up" roof covering. This describes the asbestos roofing, which is built up of sheets of pure asbestos fibre. These sheets or layers are individually waterproofed and cemented together with the company's asphalt compound.

THE KELLOGG SWITCHBOARD AND SUPPLY COMPANY, Chicago, Ill., has issued a bulletin describing its railway despatching systems and a bulletin describing the new Kellogg railway pole telephone, with supplements giving a description of Kellogg railway systems in successful operation. Some of the advantages of the Kellogg train-despatching system are the safety, care and rapidity of train handling, the selective signaling of any or all stations, and the elimination of the service of telegraphers. Another bulletin just issued by this company is devoted to its standard line of common battery telephones. In addition to the handsome illustrations and complete text, there is a special description of the new Kellogg "short back-board" wall instruments, the "steel hotel set," and the new indestructible desk stand.

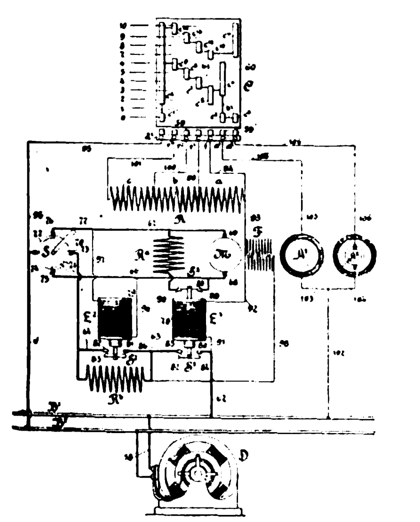
THE BLAKE SIGNAL AND MANUFACTURING COMPANY, 246 Summer street, Boston, Mass., is to be felicitated over the very complimentary paragraph which appeared in the issue of the *Evening Capital*, of Annapolis, Md., of August 1. Under the caption, "Official Route of Red Men—Washington, Baltimore & Annapolis Selected to Transport Next Tuesday's Crowd," the following statement appears: "In selecting the route the officials were impressed with the high degree of safety to which the single-track section between Naval Academy Junction and Annapolis has recently been brought by the installation of the Blake signal system. . . . A demonstration of the working of the Blake system on the single track convinced them that the Annapolis branch was equally as well protected against accident as the double-track portion of the road."

THE EMERSON ELECTRIC MANUFACTURING COMPANY, St. Louis, Mo., is distributing bulletins Nos. 3,128, 3,129, 3,130, 3,131, 3,132 and 3,906. These bulletins are devoted, respectively, to single-phase induction motors, frame 24 FA, one-twentieth horse-power, full load, automatic start; single-phase induction motors, frame 28 LA, one-sixth horse-power, full load, automatic start; single-phase induction motors, frame 32 FA, one-eighth and one-sixth horse-power, condensed type, full load, automatic start; single-phase induction motors, frame 28 JA, one-fifteenth horse-power, full-load start type, for intermittent service; single-phase induction motors, frame 28 JB, one-fifteenth horse-power, full-load start type, for intermittent service; family sewing-machine motors for Singer No. 66 drop-head machines, for alternating and direct currents. In the issue of the ELECTRICAL REVIEW for July 25 the ratings of these machines were incorrectly given.

Record of Electrical Patents.

Week of August 4.

894,818. ELECTRODE FOR THE EVOLUTION OF OZONE FROM OXYGEN OR ATMOSPHERIC AIR. John R. Craig, Jr., Glasgow, Scotland. A dielectric plate is placed edgewise between two discharging electrodes.



894,878.—VARIABLE-SPEED TRANSMISSION.

894,820. TELEGRAPHY. Patrick B. Delaney, South Orange, N. J. A transmitter having an elastic vibrator which is released when the sending key is closed.

894,826. MULTIPLE CLUSTER SOCKET. Charles D. Gervin, New York, N. Y., assignor to John H. Dale, New York, N. Y. An insulating block containing a plurality of socket shells.

894,836. RECEIVING TELEGRAPHIC AND TELEPHONIC IMPULSES SIMULTANEOUSLY. Isidor Kitsee, Philadelphia, Pa., assignor of one-half to William J. Latta, Philadelphia, Pa. A telegraph receiver is shunted by a telephone receiver circuit containing condensers and a repeating coil.

894,866. DRY BATTERY. George M. Wheeler and Henry Wilhelm, Brooklyn, N. Y. The containing shell is made up of a plurality of tubularly folded sheets, one of which is of zinc.

894,878. VARIABLE-SPEED TRANSMISSION. Henry H. Cutler, Milwaukee, Wis., assignor to the Cutler-Hammer Manufacturing Company. The change in speed is controlled by means of magnetic clutches.

894,886. AUTOMATIC CUTOUT FOR INDICATING MEANS. Albert B. Herrick, Ridgewood, N. J. A plurality of registering fingers which are brought successively into action by the handle of the instrument.

894,910. AUTOMATIC MAGNETIC CIRCUIT-BREAKER. William M. Scott, Philadelphia, Pa. An adjustable retarded circuit-breaker mechanism.

894,931. TROLLEY CAR FOR ELECTRIC MOTOR VEHICLES. Riccardo Arno and Luigi Negro, Turin, Italy. A current-collecting trolley carriage, the driving motor of which is disconnected when the main vehicle stops.

894,944. INDUCTION-CURRENT GENERATOR. Martin Fischer, Zurich, Switzerland, assignor to the firm of Actiengesellschaft "Magneta" (Electrische Uhren Ohne Batterie & Ohne Contacte), Zurich, Switzerland. Current impulses are generated by an oscillated armature.

894,945. MAGNETIC INDUCTOR. Martin Fischer, Zurich, Switzerland. Current impulses are generated by a revolving armature.

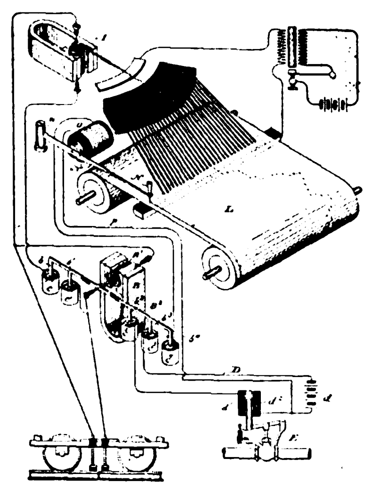
894,950. DYNAMOELECTRIC MACHINE. William T. Hensley, Wilkinsburg, Pa., assignor to Westinghouse Electric and Manufacturing Company. The commutator lead is perforated and slips over a lug on the commutator segment.

894,951. COMMUTATOR. William T. Hensley, Wilkinsburg, Pa., assignor to Westinghouse Electric and Manufacturing Company. The commutator segment is perforated and slips over a lug on the lead.

894,952. RAIL BOND. Albert B. Herrick, Cleveland, Ohio, assignor to the Electric Railway Improvement Company, Cleveland, Ohio. A rail bond built up of conducting plates cemented together.

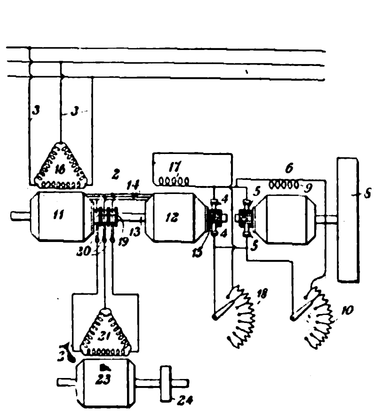
894,964. ELECTRIC RAILWAY. Joseph Mayer, Rutherford, N. J. A hinged pole supported on a double pantograph.

894,979. LOAD EQUALIZER FOR ELECTRIC CIRCUITS. John S. Peck, Manchester, England, assignor to T. H. Given, H. S. A. Stewart and E. M. Herr, Pittsburg, Pa., receivers of Westinghouse Electric and Manufacturing Company, East Pittsburg, Pa. A combination of a rotary converter having two mechanically and electrically connected rotors and independent stator windings.



894,886.—AUTOMATIC CUTOUT FOR INDICATING MEANS.

895,006. MECHANISM FOR RECOVERING, TRANSFORMING AND CONSERVING ENERGY. Léon Dion, Wilkes-Barre, Pa., assignor to the Americus Electrohermetic Company, Wilkes-Barre, Pa. The waste water of the house is utilized for driving a small battery-charging set.



894,979.—LOAD EQUALIZER FOR ELECTRIC CIRCUITS.

895,012. MOTOR-CONTROLLING DEVICE. Fletcher D. Hallock, Wilkinsburg, Pa., assignor to T. H. Given, H. S. A. Stewart and E. M. Herr, Pittsburg, Pa., receivers of Westinghouse Electric and Manufacturing Company, East Pittsburg, Pa. A motor-starting rheostat with regulating field resistance.

895,034. ATTACHMENT FOR PHOTOGRAPHIC PRINTING APPARATUS. Hervey H. McIntire, South Bend, Ind. A number of elements each mounted on an independent universal support.

895,035. ELECTRIC RAILROAD SIGNAL. Arthur W. McMaugh and Robert Welch, St. Catharine's, Ontario, Canada. A sectional centre-rail system.

895,070. TROLLEY POLE MOUNT. Edwin H. Burnes, Amsterdam, N. Y., assignor of one-third to Phœbus H. Alexander, Amsterdam, N. Y. A rotating trolley base.

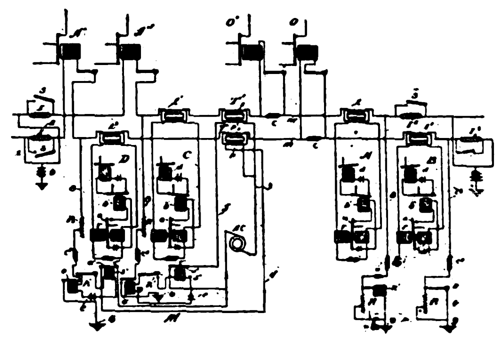
895,100. ALTERNATING-CURRENT METER. Emanuel Morck, Charlottenburg, Germany. An induction meter having two magnetic branch circuits.

895,135. CONTROLLING SYSTEM FOR LIFTING MAGNETS. Reuben I. Wright, Cleveland, Ohio, assignor to the Electric Controller and Supply Company, Cleveland, Ohio. The lifting-magnet winding is in shunt with the motor circuit, means being provided for automatically inserting resistance.

895,144. APPLICATION OF ELECTROLYSIS TO SCOURING AND SQUEEZING MACHINES. Jean M. J. Baudot, Roubaix, France. The fabric is passed between electrodes which liberate an alkaline product.

895,159. METHOD OF PRODUCING AMALGAMS OR ALLOYS. Courtland F. Carrier, Jr., Elmira, N. Y. An electric current passes from a common electrolyte to a plurality of independent bodies of fluid metal.

895,166. TELEPHONE SYSTEM. William W. Dean, Chicago, Ill., assignor to Kellogg Switchboard and Supply Company. A supervisory signal is associated with each end of the cord circuit.



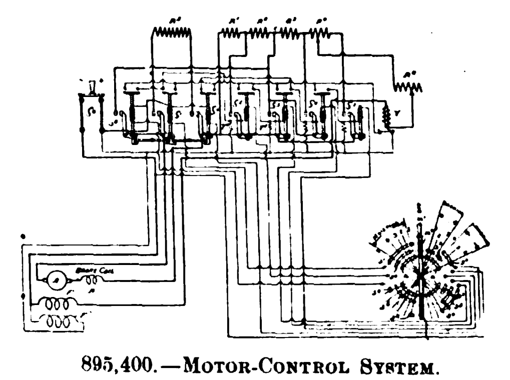
895,350.—MULTIPLEX TELEGRAPH SYSTEM.

895,199. APPARATUS FOR RELEASING HORSES. Charles C. Rich, Mount Vernon, N. Y., assignor of one-half to Harry J. Douglas, Mount Vernon, N. Y. A gravity-operated electrically controlled release gear.

895,242. ELECTROMECHANICAL MOVEMENT. George H. Davis, West Orange, N. J. The armature of the magnet is composed of a number of floating hinged sections.

895,251. TROLLEY CATCHER. George Gessert, Edwardsville, Ill. Rotatable wire guards project above the trolley wheel.

895,314. AUTOMATIC COLLAPSING AND RE-ERECTING TROLLEY POLE. George S. Thomson, Dunedin, New Zealand. A pivoted trolley pole supported by an arm which falls when the wheel leaves the wire.



895,400.—MOTOR-CONTROL SYSTEM.

895,321. TROLLEY GUARD. Charles H. Yarrington, Waterbury, Ct. Wire guards attached to the trolley wheel.

895,339. TROLLEY. Leon W. Campbell, Woonsocket, R. I. A ball-bearing wheel.

895,350. MULTIPLEX TELEGRAPH SYSTEM. Amor W. Douglas, Albuquerque, N. Mex. An alternating-current telegraph system.

895,374. MEANS FOR PERFORATING SLIPS FOR TELEGRAPHIC SIGNALING AND OTHER PURPOSES. Maximilian Kotyra, Paris, France. The punches are operated by electromagnets.

895,378. REVERSIBLE AND COLLAPSIBLE TROLLEY POLE FOR ELECTRIC VEHICLES. John Lindsay and Robert Lindsay, Dunedin, New Zealand. A trolley pole is hinged at its centre.

895,400. MOTOR-CONTROL SYSTEM. Charles D. Gilpin, Cleveland, Ohio, assignor to the Electric Controller and Supply Company, Cleveland, Ohio. An automatic motor-accelerating switch.

CONTENTS

MATHEMATICS FOR ENGINEERS.

In an abstract given elsewhere in this issue are a number of sensible remarks on the teaching of mathematics for engineers which have been taken from a longer discussion of the subject by Mr. Charles F. Scott. The problem is not simple; indeed, it is almost as complicated as that of laying out an entirely satisfactory course in any branch of engineering. One is always confronted with the question of how much time should be given to theory and how much devoted to application. We have on the one hand those who contend that the practical side of the subjects only should be taught, and on the other those who believe that each subject should be taught for itself alone. Mr. Scott holds rather to the first opinion in regard to mathematics, but he admits that the engineering student should be able to understand certain higher branches of mathematics, even though he can not, or does not, actually use them in his work.

While we agree on the whole with Mr. Scott's views, in certain respects we differ from him. In the first place, Mr. Scott says mathematics is a tool from the standpoint of the engineer; its value depends on the skill with which he can use it, and he is not concerned with the process by which the results are obtained. This is rather misleading, as there can hardly be a satisfactory use of any tool if the user does not comprehend the principles upon which it works. There is no absolute necessity for the engineer to be able to construct his tool. He may leave that to a specialist. But he must know how and why his tool does work. It is because so many college graduates do not understand the higher mathematics in this way that they do not make more use of them. The fault, no doubt, is at times due to the methods of instruction, but it must be admitted that not all engineering students are capable of becoming experts in the use of the calculus, for example, in the short time allotted to this subject in the engineering course.

It is fortunately true, as Mr. Scott points out, that at this time by far the greater number of engineers can get along satisfactorily with arithmetic, and occasionally a little elementary algebra, but they would be better equipped if they could use the higher branches with ease and certainty. We may work up to this stage in time; we were not all of us made fair arithmeticians in a generation. But it is the duty of the college to advance the professions as rapidly as possible, hence the instructors who are content to teach nothing more than they themselves were taught are not doing their whole duty. The higher branches not only are useful tools for the engineers who are skilled in them, but it becomes essential for the engineer to be able to follow their methods understandingly if he is to put to use recent developments in scientific knowledge. A notable instance of this is the development of wireless communication. The "wireless" engineer should, to-day, not only understand but be able to apply mathematical processes which are seldom taught in an engineering course.

But while asserting the necessity for advanced mathematical instruction we must not be understood as advocating the use of the higher branches in teaching science. There is danger, when such methods are employed, of laying too much stress upon the method and neglecting the thing. This is too often the case in teaching physics: the students are not given a physical conception of the principle or law—hence it means nothing to them and is of little use.

Mr. Scott says what is required of engineers is common sense, but common sense is nothing more than logical reasoning from fully understood principles; and it is no less common sense if the reasoner follow a line of thought less frequently used by others but familiar to himself. There can be as much common sense in the use of the calculus as in simple addition. But to-day this is the exception rather than the rule, because by far the greater number are more skilled in addition. And we need common sense in the teaching of science, not an obscuring of facts under a mathematical scaffold.

The trouble in teaching mathematics, as in nearly all other subjects, is the necessity of laying out a line of instruction suitable for the average student, but which will also point the way for the brilliant man to go further. The best plan, in all cases, seems to be to lay a thorough foundation of scientific principles and elementary mathematics. Upon this as high a structure of applications and advanced sciences as the time allows may be erected. The proportioning of this structure will depend upon the opinions of the instructors, but the foundation should never be weakened in the slightest, since it must bear not only the beginning of the structures which are made at the college, but the entire building which the man himself must complete. It should never be necessary for him to go back and strengthen or alter his foundations.

ELECTRICAL TRANSMISSION FOR MARINE PROPULSION.

In the issue of the ELECTRICAL REVIEW for April 4, 1908, we discussed an electrical method of propelling ships which had been proposed by Mr. Henry A. Mavor, and had been discussed before by the Institution of Engineers and Shipbuilders, of Scotland. In this system the propellers of the vessel are to be driven by induction motors, and variations in speed are to be secured by mounting the stator so that it can revolve, thus reducing the actual speed of the motor without changing the relative speeds of rotor, stator and motor. This method, while not efficient for continuous running, introduces fairly good starting conditions, and is allowable for short maneuvers, such as docking and getting under way. Under normal running conditions the stator is fixed, and the speed can then be varied only by varying that of the prime mover, unless conditions warrant the losses which will be caused by allowing the stator to revolve, absorbing the energy thus developed in friction.

Now another method of ship propulsion by means of the electric motor has been proposed and discussed by a second British society, the Institution of Marine Engineers. In this case Mr. William Durtnall, after describing the various other methods of ship propulsion by means of the electric motor, dwells at some length upon the system which he thinks offers the greatest prospect of success. In brief, he uses squirrel-cage induction motors, direct-connected to the propeller shafts, and obtains his variations in speed by means of the stator windings, which are arranged so as to develop magnetic fields having three or more different arrangements of poles. In this way a corresponding numbers of speeds is obtained, and the system will operate at all of them efficiently, though it is probable that at the lower speeds conditions may not be quite as favorable as at the higher. It would seem likely also that the motors thus constructed would be larger and heavier than those designed for the highest speed only; so that unless conditions are such as to make it essential to be able to run at two or more speeds, a less inefficient, but lighter, system might, on the whole, be better.

However this might be, it is rather interesting to note the good case which Mr. Durtnall makes out for his system as compared with the direct steam-turbine drive. As has been pointed out before, the advocates of such systems of propulsion hope to gain by driving both the steam turbines and the propellers at those speeds which give the best results. Unfortunately for the marine engineer, a large slow-speed propeller is the most efficient, while a high-speed steam turbine is the most economical of steam. Thus, in modern practice it has been necessary to sacrifice at both ends; and although turbine-driven steamers have certainly shown creditable performances, they do not do as well as they would do were it not for these limitations. This condition offers the electrical engineer an opportunity to install a system of transmission which is efficient and which will permit both the turbine and the propeller to run at their best speeds. By so doing a large saving in steam consumption is expected. For instance, Mr. Durtnall thinks that a steamer driven by four propellers, each requiring 1,000 horse-power, would require generating equipment with an output of about 3,250 kilowatts. The propellers would run at 250 revolutions per minute, and the turbines at 1,500. With steam at 150 pounds pressure, and 150 degrees Fahrenheit, it is estimated that the consumption of steam per kilowatt-hour would be thirteen pounds per shaft horse-power-hour. If the turbines were direct-connected to the propeller shafts, the steam consumption would be about twenty-two pounds per shaft horse-power-hour. Thus, in the first case, the total hourly consumption of steam would be 52,400 pounds, and in the second 88,000 pounds, a saving effected by the electric drive of forty-one per cent, and consequently an equal saving in requisite boiler capacity. At lower speeds savings nearly as good would be made by the electric equipment.

Such saving in steam, and therefore in coal, is important, but would not be allowable at too great sacrifice in weight. To determine this it is estimated that the electric equipment, including motors, generators and steam turbines, would weigh about 184 tons, while the direct-connected steam turbine would weigh only 148 tons, a difference in favor of the latter of thirty-six tons. But this is more than offset by the saving in boiler capacity, which, according to the steam consumption given above, would be 180 tons, the steam turbine requiring 440 tons of boilers, while the electric equipment requires only 260 tons. The net saving in weight will therefore be 144 tons. This, taken together with the saving in coal, which, from the foregoing, figures out at 1.6 tons an hour, or 230 tons for a six days' sail, shows the marked superiority of the electrical drive.

These conclusions should not, of course, be accepted without question. Other marine engineers might figure out considerably less advantage in the electrical drive, if indeed they did not throw it entirely the other way. Mr. Durtnall's conclusions are nevertheless interesting and worthy of careful consideration by marine engineers. While he has discussed only the steam turbine, it is not unlikely that an equally good case could be made out for an internal-combustion engine, as the electrical transmission would eliminate the handicap of this type of prime mover.

POSITIVE ELECTRICITY.

If we accept the views of the new school of electro-physicists we are fairly familiar with the character and importance of the electron, or, as some would have us believe, the negative particle of electricity. According to J. J. Thomson and others, the smallest charge of electricity which has been isolated is negative in sign, and is always associated with what appear to be particles of matter having a mass of about one-thousandth of that of the hydrogen atom. Since this mass can not be dissociated from the charge, or the charge from the mass, it has been asserted that the two things go together; in fact, what appears to be matter may be merely an effect due to the electric charge itself.

According to this theory, a positive charge or corpuscle, as Thomson calls these minute material particles, is necessary; but the positive charge has never been liberated—that is to say, it is apparently always associated with particles of matter comparable in mass with the hydrogen atom, and therefore one thousand times as large as the electron or negative corpuscle. Recent experiments by Thomson indicate the possibility of the existence of positive corpuscles, but these were still associated with large masses. A peculiarity of these positive charges was their appearance at points where they were not expected. When searching for the negative charge, one naturally looks between the two electrodes and expects to find this charge on its way from the cathode to the anode. By analogy one would therefore look for the positive charge in the same place and expect to find it moving in the opposite direction; but it has never been detected there. If it was the positive charge which Dr. Thomson noticed in certain of his experiments, this particle behaves in an erratic way, for it was found to be traveling in what seemed to be the wrong direction and in the wrong place. The particles which he noticed were traveling away from the cathode in the space beyond the anode. It was suggested that it was because of this unexpected behavior that the positive particle had not been detected before.

M. Jean Becquerel makes the most recent claim of having captured, or at least separated, the positive electron. M. Becquerel is following in the footsteps of his illustrious father, who first called attention to the then obscure phenomenon now known as radioactivity. The son has held certain ideas about the electrical theory, and devised experiments to test their accuracy. He has particularly desired to isolate the positive electron, and in a recent issue of *Comptes Rendus* asserts that he has done so.

The experiment upon which this claim is based consists in passing an electrical discharge through an exhausted tube contracted along its central portion. The anode is in one of the larger sections at one end, and the cathode is in the other, placed close to the contracted neck. The cathode plate is itself perforated to allow the canal rays from the anode to pass through it and penetrate into the other enlarged portion of the tube. These canal rays, it will be remembered, are rays which are neutral and hence are not deviated by a magnetic field. When they pass into the second portion of the tube and the surface of the latter is earthed by any means at all, this spot becomes a secondary cathode, and a phosphorescent patch appears there. This patch has an orange color, but if the hand be approached to it, the secondary cathode rays which give rise to it are driven over to the opposite wall of the tube, while a whitish patch is formed in front of the hand; and by bringing up a magnet to this patch it is found to be deflected with ease. A more elaborate tube, in which a secondary cathode was introduced in a side extension, gave the same results, but more markedly.

The conditions under which this experiment was conducted seem to be rather complicated, as there is a mixture of X-rays, cathode rays, canal rays and apparently a general mixture of every kind of electric discharge procurable within an exhausted tube.

This condition, however, seems to be necessary since, according to the author, the cathode ray is necessary to drive the positive particle out of the neutral canal ray. It is to be hoped that he will give us shortly further results of his investigation. He may perhaps devise some simpler way of ejecting the positive corpuscle from its kennel, and of studying its peculiarities of character. Certainly, if we admit the existence of the negative electron, it is hard to deny the existence of a corresponding positive charge; and our inability to dissociate this from large masses of matter is simply because we have not yet found out how. If M. Becquerel has been successful, he will have advanced our knowledge another important stage. Confirmation of his work by other investigators under other conditions is greatly to be desired.

THE TEST-METER METHOD OF TESTING SERVICE METERS II.

BY JOSEPH B. BAKER.

TESTING BY READINGS ON CONSUMER'S METER.

Of the special features of this form of test meter, next in importance to the composite field-winding—whereby the accuracy of the test meter is increased on light loads by increasing its torque, as above described—is the time-saving device for making the actual test observations by what the inventor terms the "sight method." The object of the composite field construction is to attain accuracy in testing equal to the inherent accuracy of the indicating-instrument method; and the object of the following described "sight method" of using the test meter is to attain a speed of making tests superior to the speed which it is practicable to attain by the indicating-instrument method under the largely adverse conditions of testing on consumers' premises. The method has also the advantage of doing away with the use of stop-watches.

It will facilitate the explanation of the above-mentioned device to assume that the test meter is connected for equal torque with the consumer's meter, *i. e.*, that at the given load the test meter means the same number of revolutions in a given time as the consumer's meter would make if accurate. The device referred to operates by virtually—not, of course, actually or mechanically—superposing the test-meter disc on the disc of the consumer's meter in such a way as to enable the tester to observe the actual angular amount by which the latter's disc lags behind, or advances ahead of, the test-meter disc. The device consists of a circular paper scale with its circumference divided into ten equal scale divisions, each of which is again divided into ten divisions, making 100 scale divisions in all, mounted on a circular brass plate which is slotted from circumference to centre so that it may be supported in a horizontal position on the frame of the consumer's meter,[1] the shaft of which passes through the centre of the circular scale—of course, without touching. A light pointer is fixed on the shaft so as to sweep over the scale. With both consumer's meter and test meter connected to the test load, it is obvious that if the former meter were as accurate as the latter its disc would neither lag behind nor advance ahead of the latter's disc; so if the pointer were observed at any instant to be passing over a given scale division A, it would at the end of a given number of revolutions still be found to be passing over A. If, however, the consumer's meter were slower than the test meter, at the end of the given number of revolutions the pointer on its shaft would be observed to be passing over some other point, B, back of A; and the number of scale divisions from B to A would indicate the percentage error of the consumer's meter, the corresponding meter efficiency being represented by 100 minus the lag divided by 100.

The general expression for percentage accuracy, in terms of disc revolutions, is the ratio

$$\frac{\text{Actual revolutions of the meter under test}}{\text{Allotted revolutions of same}},$$

the denominator of which would be determined by the disc constant and indicating-instrument readings on the load. Inasmuch as in the application of the method any desired number of revolutions may be "allotted" to the meter under test, counting up to that number by the observer at the test meter, the use of a slide rule may be avoided by selecting an integral number, which will facilitate making the division mentally, *e. g.*:

Allotted revolutions of meter under test = 10 (counted at test meter).

Actual revolutions of meter under test = 10.55.

$$\text{Ratio} = \frac{10.55}{10} = 1.055,$$ showing the meter under test to be 5.5 per cent fast.

In actual practice, in order to cover the use of the test meter with higher torques than the torque of the consumer's meter (as in testing on light load) the number of revolutions of the test or "standard" meter varies according to the torque of the test meter. The following description of the actual conduct of a light-load test by a team of two men, a tester and a helper, will serve to make clear the general method of reading the accuracy of the meter under test directly in percentage of the standard.

The meter is first tested on light load, and should, if accurate, make one complete revolution in exactly the same time in which the standard makes a certain definite number of revolutions, found by reference to a "table of revolutions." The helper is stationed at the standard, and, observing a white mark on the disc, in a short and sharp tone of voice gives the word "on" at the beginning and the word "off" at the end of this allotted number of revolutions of the standard. The tester is stationed at the consumer's meter, and at the words "on" and "off" notes carefully the respective positions of the pointer on the circular scale.

Mr. Mowbray states that a telephone device was added to the test meter in order to make this general method practicable for one man to handle instead of two. This device, which is attached to the form of test meter shown in Fig. 1,[1] consisted of a telephone receiver connected to a special contact on the commutator of the test meter, and giving a click for every revolution of the test meter's armature. The tester noted the clicks while observing visually the revolutions of the consumer's meter and would thus determine whether the latter were "fast" or "slow." It was found, however, that when the difference in rate of the two meters was very great, the method was inferior to the audible count of a helper stationed at the test meter, the two-man method being less confusing, especially when it was modified by the helper's audibly announcing only every third, sixth, etc., revolution of the consumer's meter. The telephone system was used for about a year, but was superseded by the method of starting and stopping the test meter electrically, described herein, which has now been in use over two years and has been adopted as the standard in the Mowbray and other test meters now being manufactured.

The percentage accuracy is at once determined by noting the number of scale divisions passed over by the pointer—*i. e.*, the number between A and B—counting around the scale in the direction of revolution of the pointer. For example, if the pointer were observed, from the word "on" to the word "off," to pass over eighty-five small divisions, the accuracy of the meter would be eighty-five per cent. The result may be expressed in a different way by saying that the number of small divisions which the pointer may need to complete one revolution is the per cent slow, and the number by which it may exceed one revolution is the per cent fast.

From the foregoing it will be noted that these methods of directly reading the error of the consumer's meter not only save the time required, in the indicating-instrument method, to reduce the result by slide-rule or pencil computations—*e. g.*, for direct-current testing, the multiplying together of indicated volts and amperes to obtain watts, the reducing of the revolutions of the consumer's meter to meter watts, and the dividing of the meter watts by instrument watts to obtain the per cent accuracy of the consumer's meter—but also save the time consumed in taking several sets of instrument readings necessitated, under conditions of varying voltage or varying load, or both, by the swinging of the instrument needles. It is obvious also that where the voltage or load varies considerably, the test meter, which actually integrates the load passing through the consumer's meter, provides a more accu-

[1] This method of testing is, of course, only applicable to meters the covers of which may be removed ("unsealed meters").

[1] Page 236, Vol. 53—No. 7.

rate reading of the load with which to compare the consumer's meter than even an impracticably large number of sets of instrument readings.

METHOD OF READINGS ON TEST METER.

An alternative method of testing, applicable to sealed meters, uses a pointer and scale attached to the standard (see Fig. 1), and is described in the article referred to in the footnote, page 236.[1] In this method the tester is stationed at the standard and observes the revolutions of its pointer, and the helper is stationed at the consumer's meter. The present forms of "Mowbray type" direct-current and alternating-current test meters, requiring but one man to perform the tests, are based on this method.

In the application of the method the procedure is the converse of that described for unsealed meters. The revolutions of the meter under test are counted and applied as the numerator of the ratio:

$$\frac{\text{Allotted revolutions of the test meter}}{\text{Actual revolutions of same}} = \text{Percentage accuracy.}$$

As the denominator would in some cases be a fractional number, a slide rule is required to make the computations quickly—only one setting of the slide rule being necessitated, however. The following example—leading to the same result as in the example of the method by readings on consumer's meter—may be given:

Allotted revolutions of test meter = 10 (counted at consumer's meter).

Actual revolutions of test meter = 9.48.

$$\text{Ratio} = \frac{10}{9.48} = 1.055$$

This form of test meter is stated to be inexpensive in first cost—consisting as it does of regular stock meter parts, and of special parts which may be made in the meter department's laboratory or machine shop—as compared with the cost of high-grade indicating instruments—voltmeter and shunt ammeter.

Japan's Electric Wire Trade.

The modern development of the electrical business in Japan has resulted in such a large demand for electric wire that the annual sale of the article amounts to about 8,000,000 yen. Of this 5,000,000 yens' worth is imported from abroad. It is admitted that the imported wire excels the home-made in quality and is generally used in warships, steamers, and also for underground work. The art of electric-wire manufacture has, however, made rapid strides in Japan of late years, and this, coupled with the ample supply of cheap copper, has reduced the cost of production with the result that the wire is offered at a price considerably lower than is charged for the imported article.

Railway Electrification Plans on the Continent.

Electrification of railways is daily attracting increased attention in a number of countries; the eventual transformation is regarded as a matter which can not be indefinitely postponed, and for which, in any case, it is advisable to prepare by investigating the natural resources and conditions bearing upon the problem and making preparatory trials, so as to pave the way for the introduction of the new order of things whenever it may be found expedient to do so. The subject, says *Engineering*, London, July 17, naturally, is rather more advanced in those countries where sufficient water power is available for the generation of electricity, but it is not confined to such localities.

Sweden is likely to assume a distinct lead as regards electric traction on railways on a comprehensive scale, for the state railways of that country have taken up the subject. Both in Norway and Denmark, also, electric railways are under consideration, and in the latter country several electric lines are likely to be taken in hand in the immediate future. Of much greater interest, however, is the preparatory work proceeding in Austria and Germany, where the respective states appear to be anxious to see the question advanced through rational and exhaustive investigations.

A distinguished member of the Imperial and Royal Austro-Hungarian Railway Board, Ober-Baurat Baron von Ferstel, recently delivered an interesting lecture on the subject, as far as it concerned Austria, at the Austrian Society of Engineers. This lecture has attracted much attention on the Continent. He first dealt with the class of railways which particularly called for electrification, and the different advantages and savings arising from it. The increasing cost of coal, he said, was an important reason for adopting electric traction; the price has risen sixty-four per cent within two years, and for the present year Austrian railways would require 730,000 tons of imported coal from German-Silesia, the Saar and the Ruhr district, and from England, the inland coal mines supplying some 640,500 tons. Matters in Austria resemble in this respect the conditions in Italy, Switzerland and Sweden, where the dearth of inland coal has an important bearing on the case for the introduction of hydro-electric power on the railways.

The consideration is emphasized, as far as Austrian Alpine railways are concerned, by the fact that the cost of transport is exceedingly high, in some cases almost equal to the cost of the coal; hydroelectric traction would seem, therefore, for more than one reason, a natural and desirable substitute for steam. Moreover, in Austria, as elsewhere, a fear has arisen that several comparatively young industries may seize upon so much water power that the state will be left in the lurch; hence the extensive purchasing of waterfalls by the Swedish State, and legislation, already effected or still under consideration, in various countries, to secure, if not a monopoly for the state, in any case a power to control and regulate the disposal of the waterfalls. This, at least, is the case of Norway, Italy and Bavaria.

In Austria the legal position of water rights appears to be regulated by a dozen and a half different territorial laws, which the speaker thought it would take a long time to adapt or alter in favor of a general state scheme. It was therefore advisable to secure the requisite waterfalls as soon as possible, prior to which, however, the question of which waterfalls were the most suitable would have to be investigated. Many of the rivers in question carry a very variable quantity of water, which, of course, is a drawback. As an instance, the speaker mentioned the Isonzo, which may have a flow of anything from a minimum of eight cubic metres per second up to more than 100. This river presents exceedingly favorable conditions of fall—over 500 feet—yet the minimum quantity of water only represents 8,000 horse-power. Its average flow of 24.5 cubic metres per second would yield 38,000 horse-power; but this would certainly necessitate the construction of a reservoir capable of holding 115,000,000 cubic metres, and of this the natural conditions will not allow. Reservoirs of this size are under consideration for other purposes at the present moment, and Baron von Ferstel mentioned the projected reservoir close to the town of Zurich as an example. It is here proposed to dam up the Sihl in a mountain valley six miles in length, rendering possible the storage of 96,500,000 cubic metres of water; the valley in question is somewhat thickly populated, and, of the total calculated cost of $2,400,000, two-thirds would be spent upon the purchase of property. The Austrian State Railways are planning a somewhat smaller reservoir for the Isonzo, based upon an average supply of fifteen cubic metres per second, and capable of holding some 48,000,000 cubic metres.

A question of importance, almost equal to that of the best possible exploitation of the various falls separately, is the proper selection, or combination for working purposes, of different falls and their power stations, in some cases, perhaps, in conjunction with steam-driven central plant; as an example, the speaker mentioned the Villach-St. Lucia-Trieste Railway, which has a hydroelectric power station at Karceit and a steam-driven station at Trieste.

Another question of importance is the possible utilization of the excess current, at times of plentiful water supply, for other purposes, such as electrochemical or metallurgical work.

The investigations carried on in Austria cover all the railway lines worked by the state railways, irrespective of their being owned by the state or by private concerns. The aggregate mileage of the railways in question amounts to 2,500 miles. In Austria the electrotechnical studies of the question, and those referring to the traffic, are so far being carried on apart from the investigation of the water-power question. In order, however, to be fully prepared with all particulars of power requirements for the different districts, and from the different waterfalls, the whole of the system of railways has been divided into 150 sections. The clubbing together of the different sections likely to come within the area of any one water-power central station will be comparatively easy and will allow of various alternatives. It is claimed that never has the electrification of a comprehensive railway system been more carefully prepared than in this case. The comparative details for steam and electric traction have been made out in as exhaustive a manner as possible. Experts in various industrial branches are also being consulted as regards the system to be chosen.

The survey of the waterfalls likely to come within the limits of this great scheme—numbering about forty—is being proceeded with and will be pushed ahead energetically during the present summer. So far plans appear to have been completed with regard to some twelve power plants, referring to a length of valley of some fifty-five miles, between the Boden Lake and the Kufstein streams; these twelve falls have an aggregate height of fall of 5,500 feet, averaging 460 feet for each station, with an aggregate minimum constant power of 41,100 horsepower.

Within the German Empire experimental electrification of railways has, of course, been carried on for several years; but the more comprehensive schemes of electrification at times put forward, as, for instance, a Berlin-Hamburg electric railway, have so far been allowed to remain in abeyance. Of late different plans of electrification have assumed more definite shapes, and, as in Austria, the whole question is now being officially investigated and reported upon, and, as far as can be foreseen at present, it is possible that the next few years may witness important developments in this direction.

Among the German states it seems probable that Bavaria will take the lead on account of the natural conditions of the country, which is rich in water power, but poor in coal. The Ministry for Public Traffic has recently prepared an exhaustive and instructive report on the question of electrification of the Bavarian state railways, advocating a classification of the state railways into two groups, of which one comprises such lines or systems of lines which, on account of the nature and extent of their traffic and their proximity to cheap water power, are well suited to electric traction. The State Railway Board is prepared to point out the requisite waterfalls as soon as the Department of the Ministry for the Interior, which deals with the water power of the country, is ready to take action in this connection. With regard to the second group of lines the adoption of electric traction may not be found expedient for some time to come and the water power, upon which this second group of railways will have to rely, is in the meantime to be placed at the disposal of industrial concerns, but only on such conditions as regards the nature and duration of the concessions and the state's option of purchase, that the state railways, when it may be found necessary, from time to time, will be able to acquire such falls or power stations. The state railways are expected to act in a spirit tending to advance the industry of the country. Military considerations also appear to have to be consulted with regard to such Bavarian railways as may, or may not, be chosen for electrification; this side of the question will, on the whole, be allowed to stand over for the present, but it may be said that the military authorities have raised no objections to some lines, of minor importance from a military point of view, being promptly electrified in order to obtain experience which should be of great value in the further development of the question. The report itself is divided into three sections, of which the most interesting is again divided into parts dealing, respectively, with the power required, the choice of system of electric traction and the economy of the proposed change. The first question to be settled was the ratio of the maximum power required to the average power. The mean figure arrived at is 3. But the actual ratios vary very much on different railways, on some of which electric power has already been adopted. Thus on the Salgburg-Berchtesgaden line the average demand is 550 horse-power, but the maximum is 2,950 —5.37 times larger than the average. On the Munich-Augsburg line the ratio is 2.58; on the Munich-Partenkirchen line we have 21,500 horse-power maximum, against an average of 5,700 horse-power —a ratio of 3.78. The calculations for the total power required by all the railways of the kingdom have been based on the assumption—derived from actual data, of course—that the requirements per ton-kilometre are 41.75 watt-hours by passenger trains, 27.2 by goods trains, and 33.4 watt-hours on local lines. That the goods trains consume less power is ascribed to the fact that they travel more slowly, and that the conditions are more favorable than is the case with passenger trains. Power is to be supplied from a great number of feeder stations. In allowing for the power capacity of these stations, ten per cent has been added to the actual figures to meet losses arising from unforeseen stoppages and delays; fifteen per cent more for the conversion of mechanical into electrical energy; twenty-five per cent more for line loss in voltage, assuming main conductors at 50,000 volts and working conductors at 10,000 volts. Making these allowances, it is thought that 142,000 horse-power would suffice on an average, and that three times that figure, 426,000 horse-power, might be required as a maximum, to deal with the whole railway traffic. Since, however, the conversion will probably occupy a good many years, and will not be completed before 1920, a further forty-two per cent has been added to these figures to meet the presumable growth of traffic during this period. Thus about 600,000 horse-power would have to be provided. It is estimated that the running waters of Bavaria offer at present still 300,000 horse-power available. When use is made of the Alpine lakes, however, and notably of the Walchensee, it will be possible to meet the maximum demand by hydroelectric installations without any difficulty. It is pointed out that the lakes could be utilized as feeders for rivers, which would not, in that case, have to be furnished with special reservoirs of their own.

As regards the choice of system, the

report sums up in favor of single-phase current. It is not considered that direct current could profitably be supplied to heavy locomotives by a third rail over distances of more than 3.5 kilometres and at a pressure exceeding 1,000 volts; the third rail would, moreover, be too dangerous at the railway stations and crossings. Three-phase currents are objected to because the motors, unless fitted with complicated mechanism, would always run at the same speed, and because they necessitate three wires and complicated switches. Single-phase current is thought to be the most suitable, though it may not be so economical for long-distance transmission as three-phase currents. The question of the recovery of the electric power on down grades has not escaped attention. Such recovery is possible, though it has not proved simple with the three-phase system, and a slight alteration would also make it possible with the Winter-Eichberg single-phase series short-circuit motors, to which it is not directly applicable. The inquiry has demonstrated, however, that only about 2.3 per cent of the absorbed energy could be recovered from the trains running down inclines, and this factor would not be decisive, therefore, as to the selection of the current system.

The cost estimates refer to special lines, some of which are already worked by electricity, notably various mountain railways on which a more elastic and more rapid service can be maintained with electric than with steam power. In some cases, for instance, on the Munich-Innsbruck line, the electric project has already assumed definite shape, and the estimates also take into consideration the necessity for relaying telegraph and telephone lines. Other items included are: Attendance on the locomotives, materials, working expenses and maintenance of locomotives, permanent way, conductors, etc. The estimates and the general conclusions are favorable to the adoption of electric power, and it is, moreover, pointed out that we must be prepared for rising prices for fuel, and that water power will hence become relatively cheaper. The lines where electric traction could forthwith be adopted comprise the Salzburg-Bad Reichenhall-Berchtesgaden Railway, and the Garnisch-Partenkirchen Railway to the Tyrolese frontier at Scharnitz and at Griesen, for which purpose an extraordinary grant is being asked. Next in consideration there come the following railways: Munich - Garnisch - Partenkirchen, Tutzing - Kochel, Weilheim - Peiszenberg, Munich - Tölz, Holzkirchen - Schliersee, Holzkirchen-Rosenheim, and the local line of Munich-Gauting. The most convenient power stations for the above lines will be the Saalach station at Bad Reichenhall (4,000 to 5,000 horse-power) the station at Lechbruck (about 20,000 horse-power), and last, but not least, the Walchensee station, which, when completed, will produce about 50,000 horse-power throughout the twenty-four hours, and at its earlier stages from 25,000 to 30,000 horse-power.

Owing to the relative cost of coal and water power the southern and southeastern parts of Bavaria are particularly suitable for the use of electric power; the freight charges on coals are very high, while water power, on the other hand, is cheaper there than further north, owing to the proximity of the Alps. In consequence it may prove economical to adopt electric traction in Southern Bavaria, even on lines with a comparatively small traffic.

In *Engineering*, Vol. lxxxv, page 660, reference was made to extensive plans of electrification on the Prussian railroads, and it would seem that the project then mentioned is not an isolated one. The department in question has urged all the different railway boards to consider the subject of the introduction of electric traction, wherever electric current can be obtained so cheaply that the railways may be relied upon to produce as good returns as at present. Among the railway boards which have gone in seriously for electrification is the one at Essen. The first line to be electrified will be the Osterfeld-Heissen-Hattingen, its passenger traffic being first dealt with in this way, and an electric railway through the Eifel, intended for the goods traffic between the Ruhr district and the Saar district and Lorraine, is also planned. The latter, however, on account of its great cost, is likely to stand over until some experience has been gained on the former line. The question of cost naturally has a deterrent effect, as, for instance, in connection with the local railways in and about Berlin, the electrification of which has often been advocated, but the cost, estimated by some at $100,000,000, has hitherto stood in the way.

The aggregate length of the Leipsic Bitterfeld-Magdeburg and the Leipsic-Halle Railway is just 100 miles, and these railways will be used for making exhaustive preliminary trials of electric traction, both as regards passenger and goods traffic.

Pennsylvania Railroad Prepares for Electrification.

A party of Pennsylvania Railroad engineers and several members of the operating department spent last Saturday studying the electrical equipment of the New York Central, with a view to getting data to be used in the final adoption of plans by the Pennsylvania Railroad for the electrification of the New York terminal and the tunnels in which the trains are to run under the Hudson and East rivers. The Pennsylvania men were conducted over the New York Central electrical zone by Superintendent Whaley and a number of his assistants.

The Pennsylvania experts will pay visits to other cities in the near future, to make a further study of railroad electrification.

The electrification of the Pennsylvania's New York terminal and its approaches will be one of the largest contracts of the kind ever attempted by a railroad. It is expected that the electrical features alone will cost in the neighborhood of $20,000,000.

Lowell & Fitchburg Bondholders' Committee.

At a meeting of the bondholders of the Lowell & Fitchburg Electric Company, of Lowell, Mass., the following were elected a bondholders' protective committee: James W. Green, chairman, and C. F. Allen, of Gloversville, N. Y.; H. S. Scofield, of Troy, N. Y.; W. H. Emhardt and Julius Christensen, Philadelphia.

The committee has formulated a bondholders' agreement to be accompanied by a deposit of the bonds, and authorizing the committee to levy an assessment on the bondholders of not to exceed two per cent of the face value of the bonds, to be used for the purpose of placing the road in position to become part of a through line between Lowell and Fitchburg, Mass. Holders of $450,000 of the total of $550,000 of bonds have signified their intention of becoming parties to the bondholders' agreement.

International Association of Municipal Electricians.

The thirteenth annual convention of the International Association of Municipal Electricians was held at Detroit, Mich., August 19, 20 and 21. Headquarters were established at the Hotel Pontchartrain.

Chicago Street Railway Affairs.

Rehabilitation of Chicago's street-car system has progressed far in advance of the requirements laid down in the franchise ordinances. One-half of the three-year rehabilitation period passed August 1, and a report which is being prepared for the board of directors of the Chicago City Railway Company shows that much more than half the work has been done. The ordinances require the city railway company to reconstruct sixty miles of electric road and thirty miles of cable lines within the specified period. Approximately seventy-five miles have already been reconstructed, and by the close of the present year an additional ten miles of new track will be laid. All the new track is laid with 129-pound steel rails at an approximate cost of $50,000 a mile. With the laying of new tracks the company has had to pave the street between the rails with granite blocks. In the last two years more than seventy-five acres of paving has been laid. Within certain districts the ordinances provide that the overhead wires be replaced with lead-covered underground distribution feeders, and this work is being carried out simultaneously with the laying of the new tracks and the building of car barns and distributing substations. To prevent electrolysis the company is installing auxiliary bare copper wires for conducting the return current back to the power-houses and substations. Twenty-one miles of this copper wire was installed last year and 23.3 miles up to August 1 of this year. An additional thirteen miles will be added during the remainder of this season. In 1907 thirty-one miles of new trolley wires, with the necessary spans, were put up, and forty-eight miles up to August 1 of this year, with a proposed addition of thirty-one miles by the end of the season. Since the rehabilitation work began the company has built car barns at the following points: Seventy-seventh street and Vincennes Road, 347 feet by 504 feet, with six bays of five tracks each and a capacity of 260 cars; Cottage Grove avenue and Thirty-eighth street, barn 336 feet by 487 feet, with a capacity of 225 cars; under construction a barn at Sixty-ninth street and Ashland avenue, 265 feet by 485 feet, with a capacity of 191 cars, and another at Archer avenue and Rockwell street, 310 feet by 400 feet, with a capacity of 210 cars. The capacity of the substations at Forty-second street and Wabash avenue and at Sixty-third street and Wentworth avenue has been increased and a new substation is being built at Forty-eighth and Honore streets. A large storage battery is to be built in the downtown district to furnish power in emergency cases in the event of a breakdown at any of the generating stations. In addition to the work enumerated the company has added to its equipment in the workshops and in the car barns.—*Railway and Engineering Review.*

Jurisdiction of the Public Service Commission Over the Hudson & Manhattan Railroad Company.

Counsel to the Public Service Commission for the First District, state of New York, has rendered an opinion concerning the powers and jurisdiction of the commission over the Hudson & Manhattan Railroad Company. The counsel is of the opinion that the commission has jurisdiction over the company and that orders concerning reports of accidents, records of stockholders, information as to car motors, and others, must be complied with. The fear has been expressed that if reports are rendered, conflicting orders may be given by the state and by the federal authorities. The company is to be assured that the commission will act within its jurisdiction in issuing any of its orders. The opinion adds:

"Inasmuch as these orders of the commission do not directly regulate interstate commerce, and, in fact, hardly even indirectly affect it, but are simply regulations upon the instruments of interstate commerce made in reliance upon the reserved police power not granted to Congress and not incompatible with any ruling that Congress has made under its power to regulate commerce, and as they certainly have less effect upon commerce than many other regulations of states heretofore upheld by the courts, like harbor regulations and laws concerning pilots, the orders would seem to me to be in aid of commerce and not an interference with it, and should be obeyed."

The International Conference on Electrical Standards.

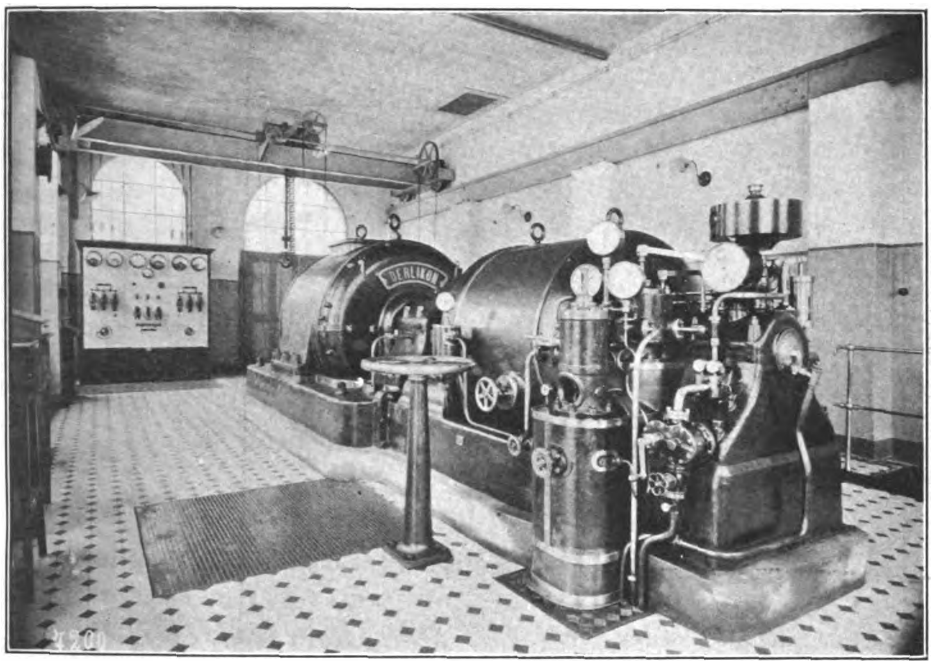
The president of the Board of Trade has appointed Lord Rayleigh, Professor J. J. Thomson, Dr. R. T. Glazebrook, Sir John Gavey and A. P. Trotter to be the British delegates to the International Conference on Electrical Units and Standards, which is to assemble in London on October 12. W. Duddell and M. G. Collins, of the Board of Trade, will act as secretaries to the British delegates, and F. E. Smith and C. W. S. Crawley as assistant secretaries.

Electrical Power in Australian Mines.

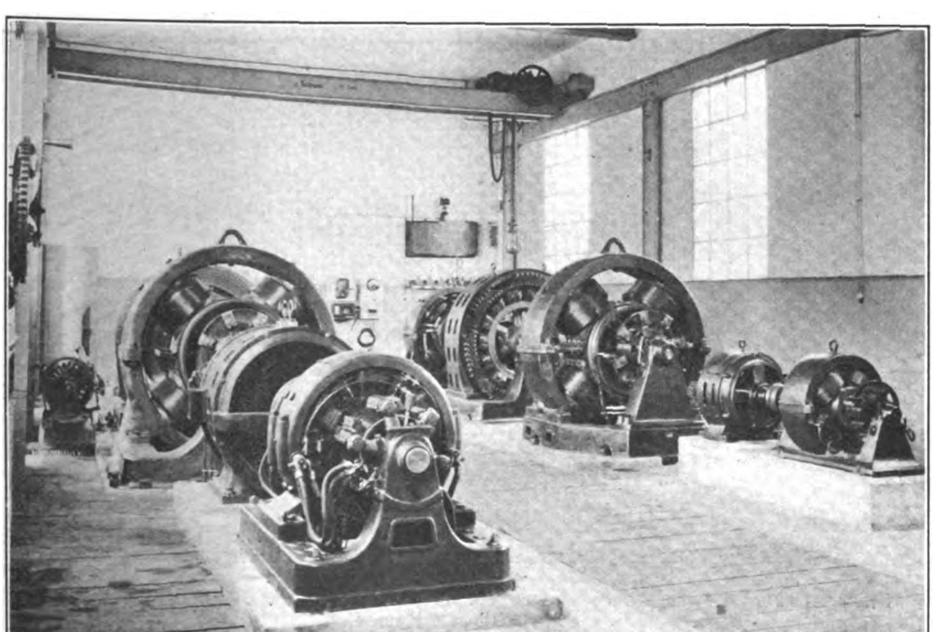
The *Australian Mining Standard* states that following the success of the earlier portion of the electrical equipment of the Mount Lyell mines, a contract has been placed for an electrically driven air-compressor with a capacity of 2,000 cubic feet of free air per minute and a final pressure of eighty pounds per square inch. This represents the application of electricity for compressing purposes on a far larger scale than anything previously undertaken in Australasia. Some new pumping plant is also on order. The North Lyell mine was the first in Australia to install an Ilgner main electrical winding plant. The new compressor will be of the two-stage type, manufactured by Messrs. Thompson & Company, of Castlemaine (V.), and will be driven at a constant speed of 144 revolutions per minute by an A.E.G. three-phase induction motor, 350 horse-power, 3,000 volts, mounted direct on the shaft between the high and low-pressure cylinders. As the output of the compressor can not be economically altered by varying the speed of the motor, an automatic mechanical device will be provided, which will cause the compressor to run light immediately a predetermined maximum pressure is reached in the receiver, and again run fully loaded as soon as the receiver pressure has fallen a few pounds below normal. The motor will be controlled by a liquid starter. The new pumping plant consists of four Pearn treble-ram electric mine pumps, each with a capacity of 6,000 gallons per hour, against a vertical head of 400-450 feet. The whole of the castings, valves, valve seats, plungers, etc., coming in contact with the water will be made of high-grade gun metal to resist the excessive corrosive nature of the mine water. Two of the pumps will be placed about 700 feet below the top of the shaft, and the other two 450 feet lower. The pumps in each chamber will be placed over the well and will be automatically stopped and started by A.E.G. patent float controllers. The motors driving the pumps will be of the three-phase slip-ring induction type, having a normal rating of twenty-five horse-power at 525 volts, but will be capable of running continuously, if necessary, at thirty horse-power. The efficiency of the pumps is guaranteed at eighty per cent and that of the motors at eighty-nine per cent.—*Electrical Engineering (London).*

Seebach-Wettingen 15,000-Volt Single-Phase Traction System, Switzerland.

FOR the last few years the Swiss engineers have been experimenting with single-phase traction, and particularly with that of the Oerlikon system. As early as 1901 the Oerlikon company made the proposition to electrify the Seebach-Wettingen line. Before receiving their franchise the company made experiments on a line between Oerlikon and Seebach and later on as far as Affoltern. To hinder matters there is a law prohibiting 15,000-volt lines from being run alongside railroad tracks and telephone systems.



INTERIOR OF POWER PLANT, SHOWING OERLIKON THREE-STAGE TURBINE—SEEBACH-WETTINGEN SINGLE-PHASE RAILWAY.

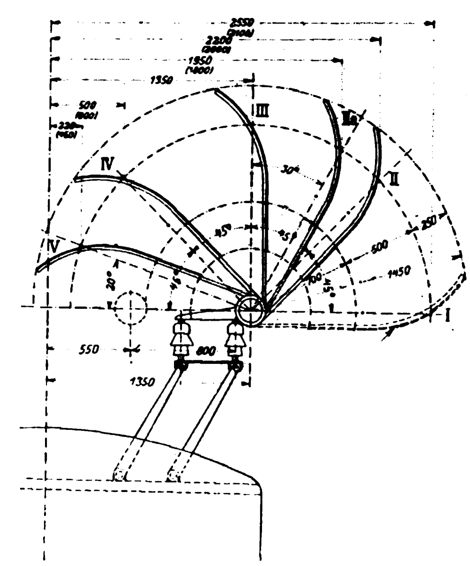


INTERIOR OF SUBSTATION—SEEBACH-WETTINGEN SINGLE-PHASE RAILWAY.

In the summer of 1904 the Oerlikon company had in operation locomotive No. 1, running at 5,000 volts, fifty-cycles. Because of the difficulties experienced in the operation of No. 1 the company built another, No. 2, to operate at 15,000 volts, fifteen cycles. This locomotive was put in operation November, 1905, and the results of the experiments carried on were such that locomotive No. 1 was reconstructed on the lines of No. 2. By the end of 1907 the whole line from Seebach to Wettingen, twelve miles, was put in operation, jointly by the Oerlikon company and Siemens-Schuckert Werke.

The section from Seebach to Regensdorf, about four miles, is equipped with the Oerlikon trolley, and from Regensdorf to Wettingen, about eight miles, with the Siemens-Schuckert trolley. There are at present three locomotives in operation, which are equipped with both systems, so that they can operate on the two systems.

There are seven stations situated along the line and no grades of any account.



OERLIKON COLLECTING DEVICE IN DIFFERENT POSITIONS — SEEBACH-WETTINGEN, SINGLE-PHASE RAILWAY.

The smallest radius of the track is 980 feet. The rails are used as a return circuit.

POWER PLANT.

Power is supplied from the plant of the Oerlikon company at Oerlikon, for which purpose an additional 700-kilowatt turbo-generator was installed. The steam turbine is of the Oerlikon type, three-stage, direct-acting, and is placed with the generator on a common bed-plate. The turbine is connected to a revolving-field generator by a needle coupling, and is provided with a jet condenser located in the basement. At the end of the generating room there is a switchboard with three panels, equipped with the necessary instruments for throwing the current on the transformer station, Seebach-Wettingen, or for manufacturing purposes. As all the equipment of the plant was 230 volts and fifty cycles, the generator adopted in this plant is the same.

SUBSTATION.

The experiments were carried on at fifty cycles, which, however, proved unsatisfactory, and fifteen cycles was adopted. The energy received from the power-house as three-phase, fifty-cycle current is transformed through motor-generator sets. The substation erected near the power-house has the following equipment: Two motor-generator sets of 700 and 500-kilowatt capacity. Each consists of a fourteen-pole, 230-volt, fifty-cycle synchronous motor with 100-volt excitation coupled on one side to a four-pole, 700-volt, fourteen to fifteen-cycle generator with 100-volt excitation. On the other end is coupled a 750 to 850-volt, 350-ampere, direct-current generator, which operates in connection with a storage battery.

The fields of the generators are regulated by two Thury regulators. When the generators are operating in parallel the regulators are mechanically interconnected by gearing and shafting.

The exciter current for the synchronous motors is furnished by a fifty-horse-power, fifty-cycle, 100-120-volt motor-generator set.

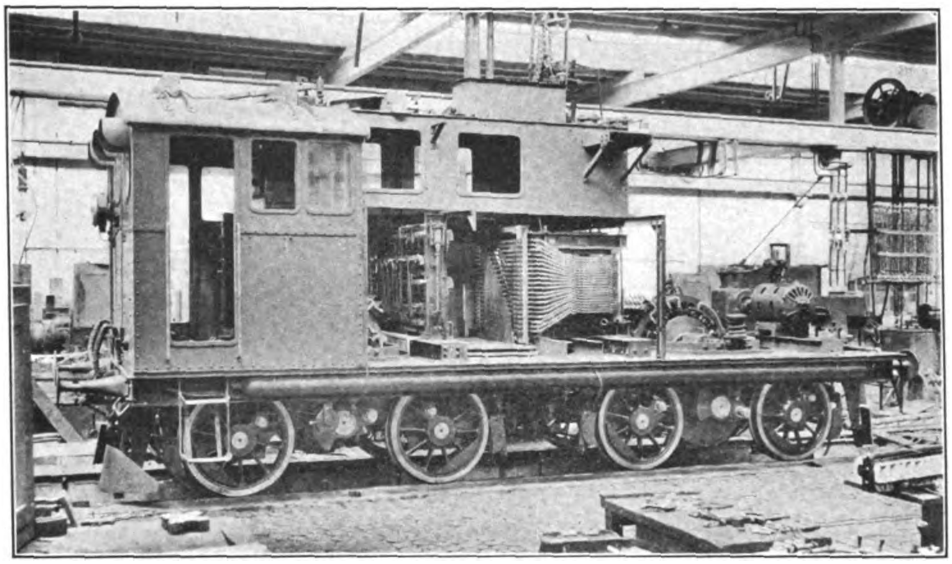
A 120-horse-power booster outfit operates in connection with the storage battery. The booster has two commutators which, when they feed the storage battery, operate in series, but when operating under normal conditions are switched in parallel. The booster is operated by a three-phase induction motor fed from the three-phase power-house supply. The regulation is done in two ways: either by a Thury regulator receiving current from the trolley line or by means of a Siemens-Schuckert converter with a differential excitation, operated by a chain drive from the shaft of the 700-kilowatt motor-generator set. The converter furnishes thirty amperes at thirty-eight volts.

The storage battery, located in a separate building, consists of 375 cells and has a capacity of 592 ampere-hours. For a period of five minutes it can give 1,200 amperes or 1,800 for one minute.

On one end of the substation is the transformer compartment in which are located four 250-kilowatt single-phase transformers to step up the 700 volts from the motor-generator sets to 15,000 volts for the trolley. There is also a 450-kilowatt, three-phase transformer receiving 30,000 volts from Hochfelden, stepping it down to 210 volts for the motor-generators, in case the power-house supply should fail.

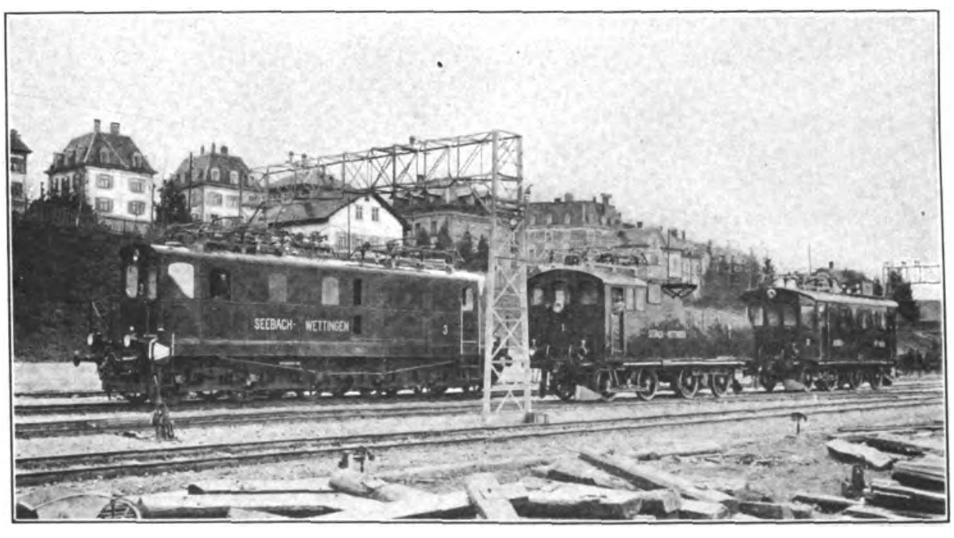
OERLIKON TROLLEY SYSTEM.

The Oerlikon trolley system is installed from Oerlikon to Seebach where it joins the main line to Regensdorf. At Seebach the wire is suspended by catenary construction from bridges with eight spans of 165 feet and 200 feet. The trolley is hung sixteen and one-half feet above the rail by steel wires about twenty-three feet apart. From Seebach to Regensdorf the trolley wire is carried on poles at the side of the track by means of semi-rigid sists of an automatic adjustable arm mounted on the top of a four-bar linkage. By referring to the illustration herewith it will be seen that the arm may occupy any position from I to V for a fixed position of the linkage. From positions I to V gives a sweep of 7.5 feet. By shifting the linkage an additional 2.5 feet is



LOCOMOTIVE NO. 1, REMODELED—SEEBACH-WETTINGEN SINGLE PHASE RAILWAY.

construction mounted on cast-iron caps fastened to insulators which are mounted on the brackets of the poles. The line is divided up into several sections. At the end of each section is a horn section switch carried on a steel pole, which also carries a semaphore. The switch operates by gained. The trolley may hang directly overhead or eight feet to one side of the centre line and the current may be drawn from the top, side or bottom of the trolley wire, thus securing great flexibility, for which the system is noted. Under ordinary conditions the trolley is at the side



FROM LEFT TO RIGHT, LOCOMOTIVES NO. 3, NO. 1 AND NO. 2—SEEBACH-WETTINGEN SINGLE-PHASE RAILWAY.

hand or automatically from the railroad station, for which purpose a pilot wire is carried on the wooden poles.

The Oerlikon collector is placed on top and to one side of the locomotive. It con- of the track, to facilitate erection and repairs. The collecting arm is held in contact with the trolley by a spring device which may be operated by hand or electropneumatically. When not in operation the collecting arm is held flat on top of the car.

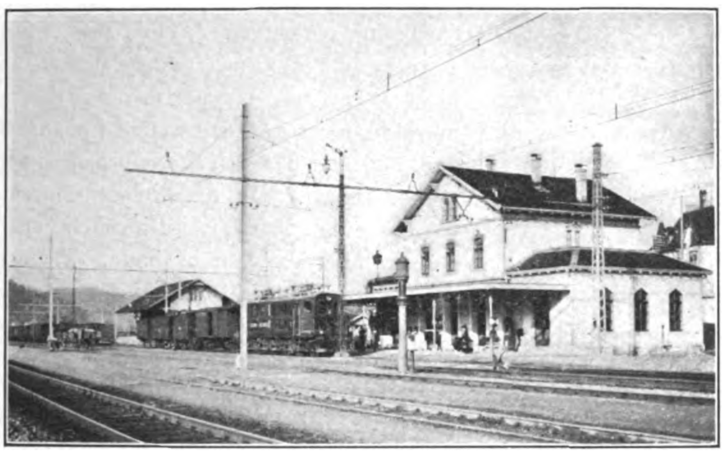
The arms are made of seamless, drawn steel tubes about 7.5 feet long and slightly bent at one end. There are two such arms to one collecting device.

SIEMENS-SCHUCKERT TROLLEY.

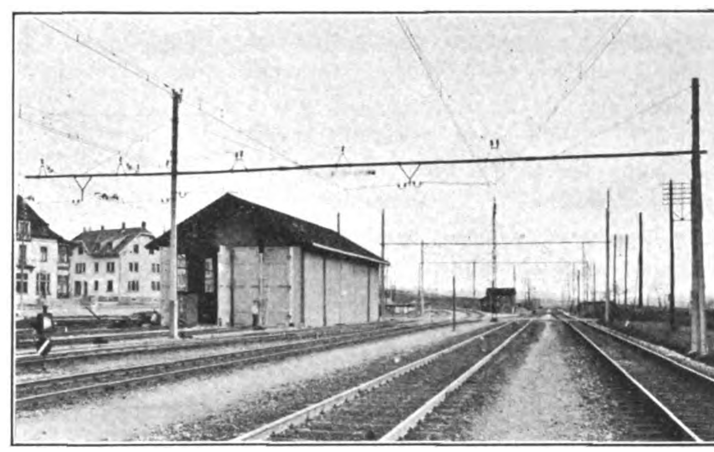
The Siemens-Schuckert trolley system starts at Regensdorf, ends at Wettingen and overlaps the Oerlikon trolleys for a distance of 1,300 feet, so that the change from one system to the other is made with- on pairs of channels spanning, in some cases, seven tracks. The overhead trolley line, with its complete catenary, is divided up into sections in order to keep them taut. The spans, in the sections where the wires overlap, are 375 feet long. For a distance of thirty-five or forty-five feet, in the middle of such a span, the wires are parallel and about five inches apart. The ends of each section are led from the centre of the track to side poles, where they are provided with a tension arrangement. locomotives No. 1 and No. 2, of the Oerlikon make, have only one pantograph, while No. 3, of the Siemens-Schuckert make, has two.

The poles on the line are placed between 160 and 170 feet apart. In some cases, for experimental purposes, the span was lengthened to 330 feet.

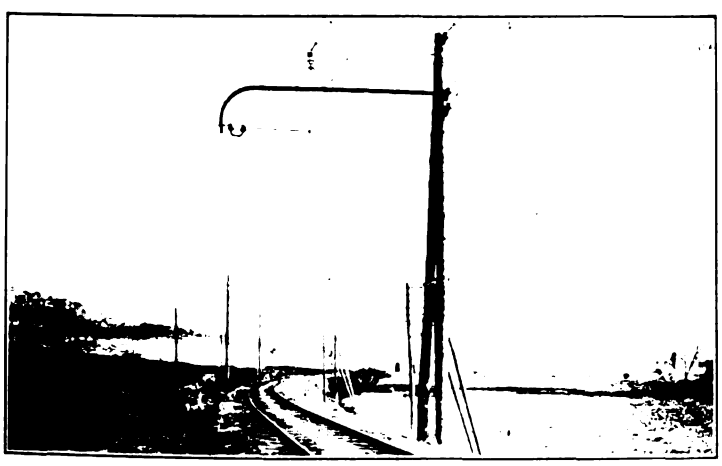
At sidings and locomotive barns the trolley wire is provided with circuit-breakers so that power may be supplied to the sidings when necessary.



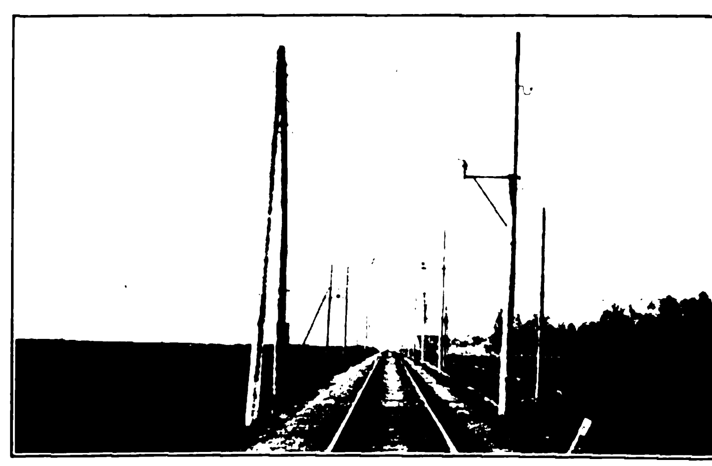
CATENARY SUSPENSION AT RAILROAD STATION AT WETTINGEN; ALSO LOCOMOTIVE NO. 3.



OVERHEAD CONSTRUCTION SPANNING TRACKS AT RAILROAD STATION, WETTINGEN.



INSIDE AND OUTSIDE POLE ARRANGEMENT—SEEBACH-WETTINGEN SINGLE-PHASE RAILWAY.



AT JUNCTION OF OERLIKON AND SIEMENS-SCHUCKERT SYSTEMS—SEEBACH-WETTINGEN SINGLE-PHASE RAILWAY.

out interruption. The trolley wire is suspended by catenary construction 19.5 feet above the rails. Between Otelfingen and Wuerenlos, for a distance of 0.6 mile, the trolley is only fifteen feet above the rail. The catenary wire, a steel cable thirty-five square millimetres, rests on cast-iron caps carried on insulators, and carries an auxiliary catenary by suspension wires 19.7 feet apart. From the auxiliary catenary the main trolley is hung by clamps from nine to ten feet apart. On the main line, the trolley is carried on side poles, while at stations it is carried The weights in the above arrangement are 600 pounds; as the sheaves have a ratio of one to two, there is a continuous pull on the line of 1,200 pounds. The sections are dead-ended at one end.

A tension arrangement is located at each station and midway between stations, so that the sections are about one mile long.

The Siemens-Schuckert collecting device is a sliding-bow pantograph arrangement. The contact piece is a removable U-shaped piece of aluminum pressed against the trolley by flat springs. The

The rails are used as a return circuit and are well bonded. Every mile and a quarter they are specially grounded by large copper plates.

STATIONS.

From Wettingen to Seebach there are seven stations along the line, on the average about two miles apart. The section switches are controlled from the stations and the keys to the switches are in the possession of the station master. At Kempfhof, owing to heavy street traffic, the sliding gates are electromechanically connected to the overhead trolley so that when the trolley is alive the gates are closed. This was done at the request of the public service commission.

LOCOMOTIVES NO. 1 AND NO. 2.

There are at present three locomotives in operation. No. 1 is illustrated herewith. This machine was built in 1904 for experimental purposes and was known as "the converter locomotive." It was later changed over into a single-phase locomotive. The converter was rated on the alternating-current side as a 650-horse-power, 700-volt, asynchronous motor and on the direct-current side as a 400-kilowatt, 600-volt generator with a speed of 1,000 revolutions per minute. Overhanging one end of the driving shaft was a 150-volt, direct-current generator which was connected to the direct-current side of the converter. This generator acted as a booster or a bucker so that various voltages could be applied to the driving motors, which were shunt wound. The line voltage was stepped down from 15,000 to 700 by two 250-kilovolt-ampere air-cooled transformers. It was found out during experiments that it would be advisable to change the equipment to single-phase, fifteen cycles, because, owing to the peculiar operating conditions (the frequent stops during which time the converter had to remain in operation), the current consumption was comparatively high, although otherwise the equipment was very satisfactory and highly efficient.

The body of No. 1 rests on two four-wheel swivel trucks, each having a 200-horse-power motor mounted between the axles. There is no king pin; the theoretical swiveling point is controlled by levers. The motor is geared to a separate driving shaft from which the drivers are operated by means of a crank-pin and connecting rod. The brakes, one for each wheel, are operated pneumatically or by hand. The total weight has been reduced from forty-eight to forty tons, due to change of equipment.

The body of locomotive No. 2 is built on the same lines as No. 1 except that it has a cab at each end for the motorman and weighs forty-two tons. It is equipped similarly to locomotive No. 1 with an Oerlikon rod collector and a Siemens pantograph collector, both having hand and electropneumatic control.

The current is led from the trolley to four transformers connected in series-parallel. Each transformer group has a capacity of 250 kilovolt-amperes. They are wound for 15,000 to 700 volt transformation, are air-cooled, and are located in the centre of the car. In the cabs, at each end, are two controllers, one for controlling the motors, the other for controlling the transformer taps.

The motors are series wound with interpoles of 250-horse-power capacity each. They make 650 revolutions per minute normally and 1,000 maximum. With a gear ratio of one to 3.08 and drivers of 39.5 inches, a speed of about thirty-six miles an hour is attained. On grades of 0.8 to one per cent a speed of twenty-four miles per hour is attained, while on short stretches of 1.2 per cent the same speed can be maintained. These values are calculated for a train weighing 250 metric tons. Tests have shown that the motors can operate just as well on twenty-five cycles.

HORN SECTION-SWITCH AND DEAD-END OF ONE TROLLEY SECTION — SEEBACH-WETTINGEN SINGLE-PHASE RAILWAY.

Each locomotive has a six-horse-power, motor-driven air-compressor operating at 140 volts. The compressors supply air at pressures between seventy-five and 105 pounds. The operation is automatically controlled by the air pressure. The air is used for operating the various apparatus, such as bow collectors, etc. Current for these motors is drawn from special taps on the transformer, which also has taps for lighting and heating.

LOCOMOTIVE NO. 3.

Locomotive No. 3 rests on two six-wheel trucks; the king pins are 19.7 feet apart. The trucks are of the same design as those of the famous Marienfeld-Zossen experimental locomotives, built by Siemens-Schuckert Werke, who also supplied locomotive No. 3. This locomotive is designed for a six-motor equipment although at present only four are mounted. Each motor has a capacity of 225 horse-power, eight poles, artificially cooled and geared to the drivers through a gearing with a ratio of one to 3.72. The design of the housing is seen in the accompanying illustration. The length over all is forty-five feet. The car is equipped with two Siemens-Schuckert collectors and one pair of Oerlikon collectors. The two transformers, of 500-kilowatt capacity each, are located in iron compartments with removable doors and are wound for 15,000, 288, 330 and 378-volt transformation and are oil-cooled. On the high-tension side there are overload circuit-breakers, operated automatically or by hand. There is provision in the high-tension compartment for the three motors of each truck, three contactors for speed control and two for controlling direction of current. The contactor compartments are placed in three tiers.

This locomotive, equipped with four motors, has a weight of sixty-eight tons, and a tractive effort of 10,300 pounds for an hour; the maximum is 17,200 pounds. When equipped with six motors the weight is seventy-five tons and the tractive effort 15,600 pounds for one hour; the maximum, 25,740 pounds.

EFFECT OF HIGH-TENSION LINES ON TELEPHONE LINES, ETC.

On the experimental section of this line, in 1904, for a distance of 2,500 feet, the 15,000-volt, fifty-cycle line ran parallel to the telephone systems. When the high-tension system was operated at fifty cycles, the operation of the telephone lines was impossible. The trouble was remedied by changing the frequency from fifty to fifteen cycles. Experiments show that even thirty cycles have little or no effect. The voltage, 15,000, remained the same. Oscillograms of the motor show that the current and voltage curves, although sinuous in character, are very ragged. This trouble was corrected by changing the slot spacing and putting the poles on the skew. The former trouble was experienced on locomotive No. 1 while the latter appeared on No. 2 after fifteen cycles was adopted.

It might be of interest to state that between December 3 and January 6 only three interruptions occurred: One insulator broke, a trolley wire slipped out of its end clamp, and a short-circuit in a substation. Encouraged by the success of this road the Swiss engineers propose to build 3,500 to 4,000-horse-power locomotives for further electrification of other trunk lines.

Decimal Classification for Indexing Electrical Engineering Data.

To the Editor of the Electrical Review:

About three years ago Mr. L. C. Marburg and the writer devised a decimal classification for indexing electrical engineering data, which we give below for the benefit of any one who may be interested. The index is constructed in accordance with the plan followed in Dewey's "Decimal Classification," and is, in fact, merely an extension of division 621.3 in that work.

For convenience the figures 621.3 representing the division "Electrical Engineering" in Dewey's index, have been omitted, but could be used if found desirable. The writer has found it convenient to use the letter "E" as a prefix when some distinguishing mark was necessary.

Considerable time and thought was spent on the classification and careful attention given to the introductory remarks in Dewey's work. Any one interested in the subject should procure this book, which is published by the Library Bureau.

In a number of the classes, the subdivisions have been carried to only two places, and classes 7 and 8, owing to the authors' unfamiliarity with the subjects, have not been subdivided at all. Further extension would, of course, be required should extensive use be made of these portions.

The index has been used by the writer with extremely satisfactory results for nearly three years, and during the past year has been also very successfully used for indexing drawings in a manufacturing establishment.

It is scarcely necessary to enumerate the many advantages of a decimal classification, as this has been so thoroughly accomplished in the book above referred to.

H. L. Van Valkenberg.

Long-Distance Wireless Telephony.

Dispatches from Paris announce that Lieutenants Colin, Jeance and Mercieri, the inventors of the wireless telephone apparatus which recent tests have shown to accomplish remarkable results, achieved a notable success with their new instruments on August 15. Communication was established between Paris and Raz de Sein, Department of Finisterre, a distance of about 310 miles. The transmitted words were faint, but could be plainly distinguished. The officers are confident that they can make improvements in the apparatus enabling the exchange of conversation up to 600 or 700 miles.

THE NATURE OF THE VOLATILE MATTER OF COAL AS EVOLVED UNDER DIFFERENT CONDITIONS.

BY HORACE C. PORTER AND F. K. OVITZ.

In connection with the fuel investigations being conducted by the Technologic Branch of the United States Geological Survey, a special effort is being made to determine the chemical and physical structure of coal. The chemical investigation is being pursued along three special lines: (1) The chemistry of combustion in the furnace; that is, determining the chemical composition of the hydrocarbons given off during the process of combustion; (2) the hydrocarbons which are given off at different temperatures, starting with a normal temperature and determining the nature of the hydrocarbons given off at each of a series of successively higher temperatures from the normal to the temperature of the ordinary furnace, and (3) the hydrocarbons existing in the coal at normal temperatures to be determined by solution and subsequent analytical methods.

A paper presented by Dr. Horace C. Porter, at the June meeting of the American Chemical Society, of which the present statement is an abstract, relates to the second of these three lines of investigation. Dr. Porter is in charge of the chemistry of the distillates of coal under the United States Geological Survey.

The statement is in part as follows:

It is a familiar fact to retort coke-oven and gas-works operators that the volatile products of coal are largely affected both in quantity and character by the conditions of temperature and rapidity of the rise of temperature in the coal, and by the conditions to which the products are subjected after leaving the coal. The usual laboratory determination of volatile matter serves almost universally as a more or less valuable indication of the coal's adaptability to industrial uses either for combustion, destructive distillation, or gasification. The method for this determination is, however, an arbitrary one and does not duplicate closely that of any industrial operation, nor is the character of the volatile matter produced by the laboratory method known with any degree of certainty. Furthermore, the results by the laboratory method are very sensitive to varying conditions and the influence of such variation on the character of the volatile products has not heretofore been the subject of extended study.

The importance of the rôle played by the volatile matter in all industrial applications of fuel is generally recognized. There are more heat units in the volatile matter in proportion to its weight than in the fixed residue. Pittsburg coal of thirty per cent volatile matter and seven per cent ash has thirty-six per cent of its heat value in its volatile matter, as shown by comparing the heat values of coal and coke. When coal is fired under a boiler, either by hand or mechanically, it first undergoes a process of distillation, and both the quantity and quality of the volatile products and the relative ease of their liberation are concerned very largely in the boiler efficiency and the production of smoke.[1] It is reasonable to suppose that coals of different origin may yield volatile gases carrying different percentages of tarry vapors and heavy hydrocarbons, and may on that account differ in smoke-producing tendencies. A knowledge of the chemical reasons why coals smoke in varying degrees, and why high-volatile coals are hard to burn with maximum efficiency is a necessary preliminary to the taking of intelligent steps toward improvement in these respects.

The gas producer for bituminous and low-grade fuels is coming more and more into favor. Here also the volatile matter in the fuel plays a very important rôle, since at the top of the fuel bed a process of distillation is continually going on. A certain proposed new type of producer will utilize high-volatile fuels, such as bituminous coal, lignite, peat and wood, by passing the hot gases from the producer through the raw fuel in a series of preliminary chambers, thus distilling the valuable hydrocarbon gases (as well as ammonia) out of the fuel before it is charged into the producer itself.

Attention need hardly be called to the pre-eminent importance of the volatile matter of coal in the illuminating gas and by-product coke oven industries. It is of interest to note, however, the increasing favor accorded by the gas industry to the vertical gas retort as most successfully operated by the Bueb system at Dessau, Germany, and to explain that one advantage of this process lies in avoiding decomposition of certain valuable gases in passing over heated surfaces, as occurs in the ordinary processes, although at the same time a higher gas yield is obtained by using higher temperatures in the retort itself.

PURPOSE OF THE INVESTIGATION.

The purpose of the investigation described in this paper has been: (1) To throw light on the nature of the volatile products from coal, and on the manner in which they are affected by the conditions prevailing during their formation or to which they are subjected after formation; (2) to contribute, in the interests of smoke abatement, some data on the comparative amount and character of the gases and vapors distilled from different coals at low temperatures, a subject intimately concerned in the production of smoke; (3) to prove experimentally that the volatile product of coal is to some extent incombustible, and that the proportion of inert volatile varies in different coals; and finally, (4) to show that the oxygen of coal is in many cases evolved in the volatile matter very largely in combination with carbon as CO and CO_2 as well as with hydrogen as water, thereby explaining in great degree the discrepancy found in these cases between the determined calorific value and that calculated by Du Long's formula.

DETERIORATION IN HEATING VALUE AT ORDINARY TEMPERATURES.

In connection with a series of experiments not yet completed, on the deterioration in heat value of various coals during storage under different conditions, a liberation of gas in remarkably large quantities was found in certain cases. About twenty-five pounds of bituminous coal of buckwheat size was stored in a five-gallon glass bottle closed with a rubber stopper, which was provided with glass tubes for removing gas samples. The bottles stood in the laboratory at a temperature ranging from twenty degrees to twenty-five degrees. In some of the bottles the coal was immersed in distilled water and the interstices well filled with water by attaching a partial vacuum for about one hour. About 400 cubic centimetres of air remained above the surface of the water.

The gas liberated during these experiments consisted almost entirely of methane with a very slight amount of CO_2 and no more than doubtful traces of CO and heavy hydrocarbons. No hydrogen could be detected by the palladium fractional combustion method. Whether this gas may properly be considered as volatile matter due to decomposition of the coal, or whether it is held in the coal as such by occlusion or absorption can not be decided without further study. The fact that the oxygen of the air surrounding the coal was rapidly absorbed without

(Presented with the permission of the Director United States Geological Survey.)

forming CO_2, indicates a change of composition in the coal. It is reasonable to suppose that a larger quantity of gas escaped between the mining of the coal and the starting of the experiments than was measured during the experiments. The measurement of quantity of gas formed is, therefore, of little value. The gas pressure in the case of one coal immersed reached at one time seven inches of mercury.

[1] Compiled from results in Table II.

VOLATILE MATTER AT 105 DEGREES CENTIGRADE.

A series of experiments conducted primarily for direct weighing of moisture driven off from coal at 105 degrees yielded results, incidentally, which showed the extent of the loss of substances other than moisture, principally CO_2 in small percentages.

VOLATILE MATTER AT 500 DEGREES TO 1,100 DEGREES CENTIGRADE.

In studying the nature of the volatile matter at the medium and higher temperatures (500 degrees to 1,100 degrees centigrade) two sets of experiments were run using a different apparatus in each. In one a small sample (ten grammes) was heated in a platinum retort suspended in an electric resistance furnace maintained constant at the desired temperature, the gases evolved being collected by displacement of water in a bottle. No attempt was made in this set of experiments to duplicate the methods or results of industrial practice. The apparatus was designed with the idea of maintaining definite and controllable conditions which would yield results comparable with each other in experiments on different coals. The other set of experiments was run on a somewhat larger scale, heating 400 grammes of coal in a cast-iron retort resting in a cylindrical electric-resistance furnace, the tar, water, ammonia, CO_2 H_2S, and gas being collected in appropriate absorption apparatus and measured. Owing to the heavy nature of the retort and the large sample of coal the temperature in the coal could not be varied as easily in these experiments as in those using the platinum retort. Accordingly one set of conditions was adopted approximating as nearly as possible those of industrial by-product coke-oven practice, and a number of typical coals compared under these conditions. The object was rather to compare the different coals with each other under this set of conditions, than to determine absolutely the industrial by-product yields; and further to determine the composition of the volatile matter from different coals under these conditions.

SERIES OF TESTS ON TEN GRAMMES OF COAL IN A PLATINUM RETORT.

The series of tests on ten grammes of coal in a platinum retort, at various temperatures, is not yet completed but has yielded sufficient results to show their approximate agreement with those obtained on 400 grammes of coal and also to indicate the composition of the gas produced from different coals in the early stages of heating at low temperatures. A thermo-couple was inserted in the retort so as to determine the temperatures under the surface of the coal itself. The tests were run in an atmosphere of nitrogen which was passed through the retort until the exit gases contained less than one per cent oxygen. The tar was collected in two six-inch tubes of absorbent cotton heated to 100 degrees centigrade and also weighed on the neck of the retort. The water was collected in a five-inch $CaCl_2$ U-tube, and always contained a slight amount of light oil driven over from the tar, causing an error of one per cent or less.

SMOKE FORMATION AND THE COMPOSITION OF LOW-TEMPERATURE GASES.

(During Early Stages of Heating)

From the results given in Table II and in different form in Table III, it may be seen that the low-temperature gases are high in illuminants and the higher homologues of methane, and low in hydrogen. Comparing the four coals at 700 degrees (565 degrees in the coal) where the gas begins to be formed in considerable amount, the Connellsville is the richest of the four coals in illuminants and heavy hydrocarbons and the Pocahontas the highest in hydrogen. The high CO_2 and CO from the Illinois and Wyoming coals accord with other experiments on these coals. The tar at 700 degrees is greater also in the Connellsville coal. The smokeless character of the Pocahontas coal may be connected more or less with the presence of considerable hydrogen in its gas at low temperatures, since the low ignition point of hydrogen tends to assist in the burning of other gases present.

From Table III the bearing of these results on smoke formation may be seen. The smoke-producing constituents of the volatile matter are here considered as including tar, and the heavier hydrocarbon gases; benzene, ethylene and homologues of methane (calculated as C_2H_6). While at 440 degrees (in the coal) the Illinois coal (and probably also the Wyoming) has produced more smoky gases than the eastern coals, at 565 degrees and higher the Connellsville produces much more. This accords with the finding in practice of greater difficulty in burning coals of the Connellsville type without smoke.

CONCLUSIONS DRAWN FROM EXPERIMENTS MADE.

1. Some coals liberate gas during storage, of a composition similar to that of natural gas, and some coals rapidly absorb oxygen from the air during storage without forming CO_2.

2. During drying in air at 105 degrees centigrade some coals lose appreciable amounts of CO_2, and most coals take up oxygen to a considerable extent, but none of those tested showed any considerable formation of combustible gases.

3. The nature of the volatile products distilled from several coals at low temperatures in the early stages of heating vary in different coals in accordance with their smoke-producing tendencies.

4. The volatile matter of coal comprises a considerable proportion of non-combustible matter varying with the type of coal.

5. A modification is suggested of Du Long's heat value calculation for coal based on experimental results showing the distribution of oxygen between hydrogen and carbon.

Fifty years ago this month—August 5, 1858—the first telegraphic messages were exchanged *via* submarine cable between Europe and America, marking a new era in communication and establishing the confidence of the world in the genius and perseverance of Cyrus West Field and his associates.

Dr. Wm. Martin Habirshaw.

At a meeting of the board of trustees of the Habirshaw Wire Company, held on August 17, the following minutes and resolutions were unanimously adopted:

"On Saturday, August 15, 1908, at Saratoga Springs, New York, William Martin Habirshaw died in the seventy-fourth year of his age.

"From early manhood Dr. Habirshaw occupied an honorable and distinguished position in both the business and scientific world.

"After retiring from the United States Navy, where he served as an engineer, he began his career as an analytical chemist, and soon rose to the front ranks in his profession. He became a member of the Chemical Society of London, and of other scientific organizations both here and abroad.

"At an early date he perceived the commercial possibilities of electricity and organized and became president and general manager of the India Rubber and Gutta Percha Insulating Company, a pioneer in this line. His sterling honesty and exceptional scientific ability gave the company a high standing. Its title was recently changed to that of the Habirshaw Wire Company, and he continued to maintain a most active interest in the affairs of the company up to the time of his death.

"For the past five years he had been a sufferer from a disease which he knew to be incurable. During this long period he faced the inevitable with calmness and bravery. His honesty, hospitality, loyalty and exceptional scientific attainments drew around him a large circle of friends to whom his death will come as a deep personal loss, in which we, his close associates and fellow members of the board of trustees of the Habirshaw Wire Company, fully share.

"*Resolved,* That, as a mark of respect for the character of William M. Habirshaw, and as an expression of our loss in his death, the works and general offices of the company be closed on the day of his funeral, Wednesday, August 19, 1908.

"*Resolved,* That a copy of these minutes and resolutions be sent to his family."

New Haven to Build Subway Through New York City.

At a hearing before the Public Service Commission for the First District of the state of New York, on August 12, Charles H. Mellen, president of the New York, New Haven & Hartford Railroad Company, stated that officials of the New Haven system were ready to operate a comprehensive subway rapid transit system from The Bronx to lower Manhattan, New York city. If necessary, the New Haven road will organize a subsidiary company both to build and operate such a system.

Mr. Mellen's declaration was brought out by a question as to whether or not the New Haven road's officials really intended to construct either the New York & Portchester or the New York & Westchester Railroad lines. Both of these systems are now controlled by the New Haven road. Mr. Mellen explained that his idea was that the New Haven Railroad management would organize a separate company for the purpose of operating a comprehensive rapid transit subway line in Manhattan and The Bronx. He stated that negotiations had been carried on with representatives of the elevated and subway systems, and that these negotiations would be renewed.

Prosperous Connecticut Tramway.

According to advices from Hartford, Ct., the directors of the Bristol & Plainville Tramway Company have voted a fifty per cent stock dividend. This means that there will be an increase in the capital stock from $250,000 to $375,000 and that the holders of the stock will get their *pro rata* share without a cent of extra outlay.

The company was organized in 1895 as a consolidation of the electric light and the tramway business of the town. When some outside parties tried unsuccessfully to buy the control of the company two years ago the leading stockholders got together and pooled their holdings for five years under trustees, and that has three years more to run. The president of the company is Miles Lewis Peck.

BOOK REVIEW.

"Drawing Instruments." Walter G. Stephan, M.E. New York. McGraw Publishing Company. Cloth. 112 pages. Illustrated. 5 by 7½ inches. Furnished by the Electrical Review for $1.

In this little work the author gives a number of useful suggestions for the selection, proving and care of drawing instruments of all kinds. He considers not only the drawing pen, the tee square and scale, but the more elaborate devices as well and describes a number of useful little appliances which the draftsman will find convenient. There are a few words also on the planimeter, pantograph and other similar devices.

THE NATIONAL ELECTRICAL CONTRACTORS' ASSOCIATION.

ITS GROWTH AND WORK.

In the year 1901 the electrical contracting business had hardly risen to the dignity of a recognized position in the building trades of the country, and almost any one with a screw-driver or pair of pliers advertised himself as an electrical engineer and contractor.

This condition made the reputable contractors feel that something was necessary to improve the trade conditions, and they believed that such improvement could only be brought about through an organization that was national in its character.

With this end in view a meeting was called in Buffalo, N. Y., on July 17, 1901, to discuss the advisability of forming a national organization composed of electrical contractors.

It was evident from the attendance at and interest in this meeting, that such an organization was believed to be a necessity throughout the country.

Many delegates who attended this first meeting represented a number of contractors from the cities in which they did business and consequently were unable to take definite action at the time of the meeting.

The sentiment, however, was so strongly in favor of an organization that the National Electrical Contractors' Association was formed at this meeting with a membership consisting of thirty-one contracting concerns.

From then until the present time there has been a steady growth, and the organization now has a membership covering practically the whole country and including a large proportion of the electrical contractors. The object of the organization is to improve the conditions in the contracting trade in every possible way, and working with other national organizations in the electrical field it has brought about the recognition of the electrical contractor and made the electrical contracting business a recognized factor in the building industry.

The association has a board of directors composed of prominent electrical contractors throughout the country, and this board is at all times ready to take up any question that the membership deems important.

The special work of the organization requiring constant attention is handled through committees.

One of the most important subjects which confronted the contractor was the question of wiring rules and the inspection of electrical work.

A committee was appointed in 1902 to take up this subject, and the work of this committee resulted in the organization being allowed the privilege of the floor at the meetings of the Underwriters' National Electric Association, and also a membership in the National Conference on Standard Wiring Rules.

The policy of the organization has been to make rules more definite and strict, in order to raise the standard of electrical construction work. Also, to bring about a uniform interpretation and enforcement of the rules as embodied in the National Electrical Code, and much progress has been made along these lines.

The matter of legislation for the licensing of electrical contractors is another matter of great importance to the trade, and the National Association has advocated the passage of proper license laws, both by state and municipal government.

The committee dealing with this subject has collected and is still collecting valuable data, which are furnished to any of the members who desire to take up the question of such laws.

Another subject that early occupied the attention of the association was the difficulty in figuring electrical wiring installations on account of the different symbols in use by the different architects and engineers.

Feeling that a uniform set of symbols would be of great benefit not only to the contractor but also to the architect and engineer, a committee was appointed to take up this subject.

The work of this committee resulted in the adoption of a set of standard symbols which have been adopted by the American Institute of Architects and several departments of the United States Government.

The use of these symbols saves the contractor much annoyance and lots of time in making estimates, and prevents many misunderstandings.

Along this line a committee is now working on the subject of uniform specifications, and will undoubtedly report a draft of such a specification at the next meeting.

The question of labor, which is, of course, important to any organization composed of parties interested in the building trade, has been carefully considered by a standing committee appointed by the association for this purpose.

This committee has collected a great deal of data on the subject, which are available for the use of the members at any time.

In addition to this the ability to obtain information and assistance from all sections of the country is of great benefit to members of the national association.

The question of buying and selling material is one that is always important to a business organization, and a standing committee to consider this subject was one of the first committees appointed by the association.

From the start the organization has felt that the proper regulation of buying and selling conditions could only be accomplished through concerted action by the manufacturers, jobbers and retailers, or in the electrical business, the contractor.

The association is working along these lines and believes that eventually a condition will prevail that will be satisfactory to all parties interested in the electrical industry.

Believing that improvement always results in co-operation in any line of business, the organization has a special committee which is a part of the Co-operative Electrical Development Association, and it is believed that working with this organization will result in benefits to the contractor as well as to the electrical business in general.

In connection with the work of the national association, a publication was started in 1901 called *The National Electrical Contractor*.

It seems an almost self-evident fact that under existing business conditions, organization is necessary in every line of trade, and considering the broad lines on which the National Electrical Contractors' Association was formed, and the extremely moderate fees for membership, it should be supported by every reputable contractor in the country, who is interested in the advancement of the business.

Reconstructing the Hauser Lake Dam.

On July 28 construction forces of the Stone & Webster Engineering Corporation began clearing the site of the Hauser Lake dam, preparatory to the work of erecting a new structure. The contract for this work was signed with the Missouri River Power Company on July 11. It provides for the construction of the Hauser Lake dam, together with a second dam and power plant of 30,000 horsepower at Wolf Creek, on the Missouri River, a few miles below Hauser Lake. Both plants will supply Helena and Butte, Mont.

It will be remembered that quite recently the Hauser Lake dam was destroyed as the result of extreme high water in Wolf Creek.

FINANCIAL REPORTS OF ELECTRICAL COMPANIES.

ONEIDA RAILWAY COMPANY.

The report of the Oneida Railway Company, Oneida, N. Y., for the quarter ended June 30 shows gross of $73,029; expenses, $44,061; net, $28,968; other income, $52; charges, $5,540; total income, $29,020; surplus, $23,480.

UTICA & MOHAWK VALLEY RAILWAY COMPANY.

The report of the Utica & Mohawk Valley Railway Company for the quarter ended June 30 shows gross of $273,162; expenses, $157,277; net, $115,884; other income, $3,186; total income, $119,071; charges, $81,859; surplus, $37,212; an increase of $31,599 over the same period of last year; cash on hand, June 30, $79,640; profit and loss surplus, $538,789.

NEW YORK & NEW JERSEY TELEPHONE COMPANY.

The report of the New York & New Jersey Telephone Company for the six months ended June 30 shows gross of $4,514,512; expenses, $3,245,354; net, $1,269,158; interest, $78,117; surplus, $1,191,041; dividends, $883,225; surplus, $307,816; an increase of $15,690 over the same period last year.

SYRACUSE RAPID TRANSIT RAILWAY COMPANY.

The report of the Syracuse Rapid Transit Railway Company for the quarter ended June 30 shows gross of $321,736; expenses, $184,168; net, $137,568; other income, $1,112; total income, $138,680; charges $103,937; surplus, $34,743.

THE MEXICAN TELEPHONE AND TELEGRAPH COMPANY.

The report of the Mexican Telephone and Telegraph Company for the three months ended May 31 shows gross of $93,194; expenses, operating, $37,706; maintenance, $13,776; net, $41,712; construction, $20,812.

AMERICAN TELEPHONE AND TELEGRAPH COMPANY.

The report of the associated Bell companies, not including the long-distance lines, of the American Telephone and Telegraph Company for the month of June and six months ended June 30 shows: For June—telephone revenue, $10,012,700; general operating and maintenance expense, $7,388,300; net, $2,624,400; sundry earnings, net, $151,800; total net earnings, $3,076,200; interest, $644,700; available for dividends, $2,431,500. From January 1 to June 30—telephone revenue, $58,827,400; general operating and maintenance expenses, $43,424,700; net, $15,402,700; sundry earnings, net, $2,509,400; total net earnings, $17,912,100; interest, $3,902,600; available for dividends, $14,009,500.

CANADIAN GENERAL ELECTRIC COMPANY.

The report of the Canadian General Electric Company for the year ended December 31, 1907, shows profit on operation of $722,433; interest written off, etc., $368,206; balance, $354,227; dividends, $488,000; deficit, $133,773; previous surplus, $69,035; profit and loss deficit, $64,728. On April 1, 1908, a quarterly dividend of one and three-quarters per cent was paid on the $4,700,000 common stock, and a semi-annual dividend of three and one-half per cent on the new preferred stock, reducing the annual rate on the common stock to seven per cent.

W. R. Brock, president of the company, says: "The company has continuously, for the past nine years, paid a dividend of ten per cent, but the directors have considered it prudent to make the reduction (to seven per cent) in view of the present uncertainty of trade conditions, which we may all hope will only be temporary.

"The payment of a ten per cent dividend commenced in 1899, and from that time until the end of 1907 $2,478,469 has been paid out in dividends. Since 1900 $1,161,504 has been written off. A surplus of undivided profits and premiums on stock issues is carried forward, amounting to $1,763,668, and there is a balance at the credit of profit and loss of $73,906. The total of all these items (not including payment of interest on borrowed capital) reaches the sum of $5,477,548, which we believe is a most creditable showing for a rapidly expanding industry which charges all experimental and development work to operating expenses."

ILLINOIS TRACTION SYSTEM.

The report of the Illinois Traction System for the year ended December 31, 1907, shows gross earnings, interurban, $1,610,257; local street railway, $1,226,591; gas, $259,572; electric light and power, $542,032; steam heating, $127,453; miscellaneous, $13,282; total gross earnings, $3,779,187; operating expenses, $2,065,424; taxes, $63,063; net earnings, $1,650,699; interest on bonds, $985,631; dividends on preferred stock, $201,953; surplus, $453,115.

The system extends from Danville, Ill., westerly to Urbana, Decatur and Springfield, and northerly to Peoria and Bloomington, and southerly *via* Staunton and Edwardsville to East St. Louis, with extensions building or projected to St. Louis, Mo., and Jacksonville, Ill. There were 8,132,069 passengers carried, the car mileage operated, including company freight, being 5,336,721. The average fare per passenger was 17.54 cents. The gross earnings per revenue car-mile were 31.49 cents. The passenger earnings per passenger-car-mile were 30.55 cents. The express and freight earnings per express and freight-car-mile were 33.13 cents. The total expenses per car-mile were 17.34 cents. These figures are for interurban lines only. On the city lines 26,276,649 passengers were carried, and 6,594,500 car-miles operated. The gross earnings per mile of track were $11,525. The average fare per pay passenger was 4.66 cents. The gross per car-mile was 18.2 cents. The expenses per mile were 9.76 cents.

CHICAGO RAILWAYS COMPANY.

The report of the Chicago Railways Company for the month of May and four months ended May 31 shows May gross of $902,482; expenses, $600,353; May net, $302,129. Four months' gross, $3,384,475; expenses, $2,399,831; four months' net, $984,644; an increase of $54,534 over the same period of last year.

KANSAS CITY RAILWAY AND LIGHT COMPANY.

The report of the Kansas City Railway and Light Company for June shows gross of $515,441; expenses, $298,735; net, $216,606; interest and taxes, $155,318; June surplus, $61,288.

INTERNATIONAL RAILWAY COMPANY.

The report of the International Railway Company, Buffalo, N. Y., for the quarter and six months ended June 30 shows as follows: April 1 to June 30—gross, $1,084,540; expenses, $658,797; net, $425,743; other income, $17,846; total income, $443,589; charges, $254,537; surplus, $159,052. January 1 to June 30—gross, $2,072,171; expenses, $1,319,060; net, $753,111; other income, $33,704; total income, $786,815; charges, $566,967; surplus, $219,848.

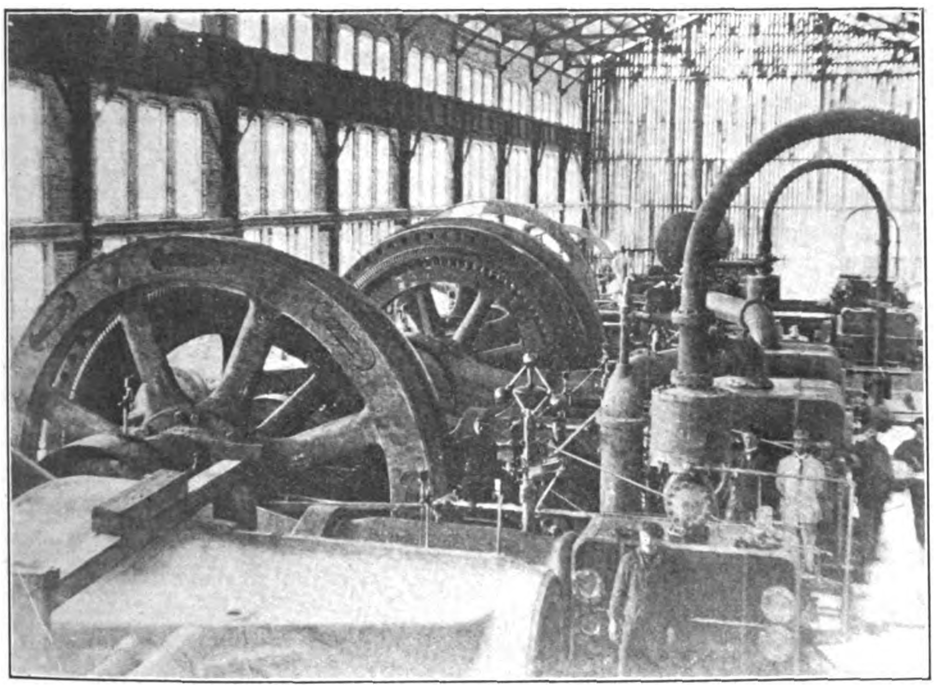
ROCHESTER RAILWAY COMPANY.

The report of the Rochester Railway Company for the quarter ended June 30 shows gross of $659,094; expenses, $435,528; net, $223,565; other income, $1,066; total income, $224,571; charges, $122,490; surplus, $102,082. This compares with a surplus of $111,012 for the same period of last year.

The Equipment of a Great Smelter — Electrically Operated.

The power-house of the Steptoe Valley Smelter, which compares favorably with the magnitude of the works of which it is a part, says Leroy A. Palmer in the *Mining World,* represents an outlay of $800,000. The boiler room is 240 feet by fifty-five feet, steel frame, iron sheathed, containing nine 400-horse-power Babcock & Wilcox water-tube boilers with Foster internal superheaters generating steam at 150 pounds pressure. One of these boilers is used to superheat the steam from three similar boilers placed in the flues of the reverberatory building and using the waste heat from the furnaces. It is expected that sufficient power will be obtained from this source to run the concentrator. The other eight boilers are arranged in two batteries of four each, fuel being fed by American stokers, which receive it by gravity from the bins. The two batteries are identical, except that one is equipped with Sturtevant and the other with Green fuel economizers. Each has a steel stack eight feet in diameter and forty feet high. Boiler draft is furnished by a National blower and stack draft by a Sturtevant blower. The ashes are discharged into a launder in the concrete floor beneath the grates and flushed out. The feed-water passes through the economizers and filter before it is injected into the boilers, a ten by eighteen by eight-inch Epping & Carpenter twin-tandem and two ten by seven by ten-inch Snow pumps being used for this purpose. By means of this preliminary heating and the use of the water from the condensers the boilers receive their feed at a temperature of about 250 degrees Fahrenheit, effecting a considerable economy in fuel, and the condenser water being distilled does not scale the boilers, materially reducing the cost of maintenance.

The power-house adjoining the boiler room is built of brick on a steel frame with reinforced concrete foundation and piers, occupying a ground space 320 feet by sixty feet. The main floor contains the switchboard, two exciters, one steam and one motor-driven, and eight condensing engines as follows: Two cross-compound Corliss, thirty-one by sixty-six by forty-eight inches; two twenty-two by forty-eight by forty-eight-inch Allis-Chalmers cross-compound Corliss, the latter direct-connected to 800-kilowatt generators and the former to 1,500-kilowatt generators, all of Allis-Chalmers Company's build; one Allis-Chalmers cross-compound Corliss duplex tandem compressor, sixteen by thirty-four by forty-eight by thirty-four, having a capacity of 6,000 cubic feet of free air per minute, supplying low-pressure air to the furnaces; one cross-compound Corliss tandem-connected duplex compressor, steam cylinders twenty-five by fifty-four by forty-eight inches and air cylinders forty-eight by forty-eight inches, having a capacity of 12,000 cubic feet of free air per minute, furnishing low-pressure air to the furnaces; one cross-compound, tandem-connected, two-stage compressor eleven by twenty-one by twenty-one by twelve by eighteen, capacity 980 cubic feet of free air per minute, supplying air at 100 pounds pressure for the forges and construction work; one tandem compound Corliss, direct-connected to a No. 10 Connersville blower with a capacity of 300 cubic feet of free air per revolution.



Steptoe Valley Smelting and Refining Company, McGill, Nev. Two 800-Kilowatt Allis-Chalmers Generators Direct-Coupled to Two Cross-Compound Engines.

These engines are equipped with steam reheaters by which the exhaust from the high-pressure cylinder is heated, thereby raising the temperature and consequently the pressure of the steam before entering the low-pressure cylinder. Steam-driven vertical pumps exhaust the air from the condensers, to which cold water is supplied by pressure from the main, doing away with the water pump usually used in this connection.

Electricity is generated at 660 volts and transmitted to a concrete transformer house where it is stepped up to 40,000 volts for transmission to the mine and 13,200 volts for transmission to the concentrator, where it is retransformed to 550 volts.

All motors are Allis-Chalmers three-phase, alternating-current, operating at 550 volts. Among these motors the following equipment may be mentioned:

First Floor—Six sets of rolls and twenty-four trommels driven by two 150-horse-power motors; twenty-four jigs and twenty-seven Wilfley tables driven by one seventy-five-horse-power motor; two elevators, each driven by a ten-horse-power motor. Jigs and trommels are on a raised platform above the floor proper.

Second Floor—Eight Huntington mills, driven by two seventy-five-horse-power motors; four elevators and eight Callow screens driven by four ten-horse-power motors (the screens on an elevated platform), and seventy-nine Wilfley tables driven by a seventy-five-horse-power motor.

Third Floor—Ninety-six Frue vanners driven by a seventy-five-horse-power motor.

Building and machinery piers and floors are of reinforced concrete, spaces being left in the floors to serve as launders. The building itself is steel frame, iron sheathed.

In general, all machinery is so installed as to be most convenient for operation and repairs, although there are some changes that would commend themselves to the practical mill man. All elevators are in pairs, set very close together with the boots some feet below the floor level, and on the roll floor so close to the rolls as to be extremely difficult of access in case they choke down.

REVIEWS OF CURRENT ENGINEERING AND SCIENTIFIC LITERATURE

Some Aspects of the Power Problem for the Textile Industry.

Each of the various methods employed for driving textile mills has certain peculiar advantages, so that the problem of selecting a drive for such a mill is not always easy. The electrical drive has shown excellent results, and its advantages have frequently been pointed out, though usually in some general terms. In this article C. J. Cavanagh considers them more specifically, and points out wherein this system is better than the others. The requirements of the textile industry are characteristic. The materials worked with are neither coarse nor heavy, but extremely fragile, and consequently the machines required to work them must be sensitive and as free from cyclic variation as possible. In the cotton industry, the evenness of turning is of first importance, and this necessity is much more emphasized in the jute and flax industries, where the materials worked have not the elasticity of cotton. It is the ability thus obtained to run the mill constantly at full load, thus securing an increased rate of production, that justifies the installation of an electrical equipment, because the interest on capital charges for an electrical system will increase the cost of power; and a well-installed, carefully maintained rope drive will give rise to very small frictional losses. However, in addition to the improved running conditions secured by the electrical system, this method brings advantages to a growing mill, as changes can be wrought easily and expansions effected with convenience. There is no loss in transmitting power to idle machines, and a hot bearing affects only the particular machine on which it occurs; in a mechanical drive, when a hot bearing may shut down a whole line shaft and stop production, the loss which it causes becomes severe. In selecting a type of motor for a textile mill, two complicating conditions are met. The polyphase induction motor is simple in operation and is sparkless; but its speed can not easily be regulated. The direct-current motor, on the other hand, is ideal for speed regulations, and simple in operation, but sparking at the commutator can not always be avoided. In a textile mill, where the air is full of fluff, sparking introduces some danger. In deciding between group or individual driving, the commercial factor enters largely into the question. With some machines, the power absorbed is so small that it is not advantageous to make use of an individual drive as these low-rated motors run at high speeds and generally necessitate some form of reducing gear. This increases the cost and the losses, and the liability to breakdown. In some cases the nature of the load renders group driving imperative. The ideal method of supplying power for the mills would be the erection of a central station, from which power would be distributed through a group of local mills. This would not only decrease the capital outlay by the mills, but would result in a more reliable and more efficient station. The type of prime mover most used to-day in textile mills is the steam engine, but the steam turbine has a distinct advantage in the uniformity of rotation, and hence is coming into use. The gas engine offers the mill a very efficient prime mover, but until greater reliabilty is secured, it will not make very great headway.—*Abstracted from Cassier's Magazine (New York), August.*

Diversity-Factors.

The "diversity-factor" is defined as the ratio of the sum of all the consumers' maximum demands to the maximum demand on the station. F. Fernie thinks a better definition is the following: "The diversity-factor is that number by which the sum of the consumers' maximum loads must be divided in order that this sum may equal the maximum observed load on the station." The author then discusses the use of this factor in determining the cost to the station of supplying any one consumer. According to the maximum-demand system, the cost is made up of three parts: That part of the capital charge per kilowatt which depends on the station's maximum demand, multiplied by the maximum demand of the consumer, and divided by the diversity-factor: to this must be added that part of the capital charges per consumer, which depends on the number of consumers; and a charge depending upon the number of kilowatt-hours used, multiplied by the running cost per kilowatt-hour. This method of charging assumes that every consumer affects the station's maximum load in the same way, but it is very certain that at the time of maximum load on the station some consumers will be making no demand, some perhaps half their maximum and some their full maximum; hence the method of charging is not entirely logical. If, instead of considering individual consumers, one considers groups of consumers, each group consisting of consumers of a similar class, at an approximately similar load-factor—that is to say, each group consisting of shops or residences only—consumers of similar class, having approximately similar load-factors, may then be supplied at a similar cost per unit: and for any station there is a certain consumers' load-factor above which the cost per unit alters very slowly; hence a group of high-load-factor consumers may vary a good deal among themselves and still be charged at a uniform rate, without any great error. The consumers being split up into groups, the question then arises, What is the correct rate per kilowatt-hour for each group? This must depend on the maximum demand made by the group on the station. The maximum demand of any group depends on the class diversity-factor of the group: that is to say, on the diversity-factor existing among the members composing the group. This factor will have very different values for different groups. The total cost is then made up of three items: The actual running cost for the number of kilowatt-hours used: an item to cover that part of the capital charges per consumer, which depends upon the number of consumers in the group, and a charge depending upon the diversity-factor of the individual and of the group. The latter item is found by dividing the sum of the maximum demands of the individuals in the group by the diversity-factor of the group, and dividing this again by the diversity-factor of the group as a whole. The quotient is then multiplied by that part of the capital charges which depends upon the station maximum demand. The author shows how this method of charging will affect the cost of the supply to different classes of consumers; for example, shops which close early should be charged about sixteen cents a kilowatt-hour; banks and offices, about fourteen cents; shops which close late, from six to twelve cents; private houses, from six to four cents; power consumers, two cents or less; railways, one and one-half cents or less, etc. In applying this method there would be some difficulty in determining the diversity-factors, but by careful grouping of consumers, and judicious selection of individuals whose maximum rates are determined, these factors can be found without much labor. It is a good plan to supply consumers at separate rates for light and power, but this calls for separate wiring, which is always objected to; hence a combined light and power rate might be adopted, and this would doubtless lead to a rapid development in the sale of small motor-driven appliances for household use.—*Abstracted from the Electrician (London), July 24.*

Generation and Electrical Transmission of Power for Main Marine Propulsion and Speed Regulation.

An abstract is given here of a discussion by W. B. Durtnall of the various electrical schemes proposed for adapting the steam turbine, which is inherently a high-speed machine, to driving ships' propellers, which run best at much lower speeds. These plans in general contemplate the direct driving of the generator of either the direct or alternating-current type, and furnishing power to a slow-speed motor whose speed can be changed at will. The plans also make it unnecessary to install a reverse turbine, and they bring the control of the vessel more under the hand of the navigating officer. In one of these plans synchronous generators drive induction motors wound to give three speeds ahead; in another, single-phase commutating motors are employed; in a third, the turbines are directly connected to the propeller shafts at full speed, but are disconnected at low speeds, when the propellers are driven by motors drawing their power from a separate turbine unit. The author prefers a direct-current system for low power, and a three-phase, alternating-current system for large powers, using squirrel-cage induction motors with stator windings providing three speeds, coupled to the propeller shafts. He then compares a system of this kind with direct propulsion by means of steam turbines. Assuming a vessel provided with four propellers, each requiring 1,000 brake-horse-power at 250 revolutions per minute to drive it, if polyphase induction motors with wound stators be adopted there should be two turbo-alternators with exciters capable of generating between them 3,250 kilowatts and running at a speed of 1,500 revolutions per minute. At full speed the turbines would consume about sixteen pounds of steam per kilowatt-hour, or 52,400 pounds total. This corresponds to thirteen pounds per shaft horse-power-hour, which compares favorably with what would be required if direct-coupled turbines, working under similar speeds and circumstances, were adopted; as in the latter case the consumption would be about twenty-two pounds per horse-power-hour, or 88,000 pounds per hour. The electrical transmission would, therefore, save about 36,000 pounds of steam per hour, which is forty-one per cent, and would reduce the boiler capacity in the same proportion. At half-speed one of the alternators could be shut down, and the steam consumption would then be about 17,760 pounds per hour. This is allowing the generator twenty-four pounds of steam per kilowatt-hour, at a load of 740 kilowatts. Under the same conditions, direct-connected turbines would consume about 28,200 pounds of steam per hour; so that the electrical drive shows a saving of about thirty-seven per cent under these conditions. The author estimates that the total weight of the electrical system would be 184 tons. The weight of the direct-connected turbines would be 148 tons, so that the former equipment weighs twenty-five per cent more. These figures do not include the boilers. The boiler equipment for the electrical system would weigh about 260 tons, while that for the direct-connected turbine system would weigh 440 tons, a difference in favor of the former of 180 tons.—*Abstracted from the Electrical Engineer (London), July 24.*

Teaching Mathematics to Engineering Students.

Practising engineers are to-day showing an unusual amount of interest in the education of young men for this profession. Charles F. Scott has for some time paid considerable attention to the subject, and has frequently expressed himself on various phases of the problem presented to the colleges. He here gives his views of what should be attempted in teaching mathematics to the engineering student. Recent classifications of the graduates of technical colleges show that not more than one-half are in occupations requiring advanced mathematics, and probably not more than one-third of the men classed as mechanical and electrical engineers ever use anything higher than simple arithmetic: hence a goodly proportion of engineering graduates do not need to be mathematical experts. Their mathematical studies need not aim to produce experts, but should have as a principal object mathematical training, which is a most efficient training in an engineering course. On the other hand, engineers who do have practical use for the higher mathematics find that their ability as engineers is, in a large degree, determined by their ability as mathematicians. Engineers are apt to use ordinarily the methods with which they are most familiar and which will bring the result with the least effort; hence skill in the use of mathematics is the really essential thing. A judicious use of arithmetic, with a little algebra, or a simple diagram, often leads to more satisfactory results than others can secure through more elaborate processes. The pure mathematician delights in relations, and, so far as possible, divorces his equations from actual phenomena and gives them abstract expression. The engineer, on the other hand, is concerned with the natural phenomena; he demands a physical conception, and the medium of expressing this relation is of secondary consequence. In the teaching of mathematics for its own sake stress is apt to be laid upon the process of deriving results, rather than on the real meaning of the results themselves. In teaching mathematics, the first difficulty is that the work must be laid out for the average student, as there is no possibility of differentiating between the men who will need only the simplest processes and those who should have more advanced training. The student should have enough mathematics to enable him to demonstrate the important engineering laws and formulas and to read intelligently mathematically written engineering literature. The student should understand something of the power of advanced mathematics and the field of its efficient application, although he may not be expert in using it himself. If mathematics is something for engineers to use, let its use be taught to engineering students. After the fundamentals are learned, students should attack the engineering problem at once, and bring in mathematics as a means of solving it. In mathematical training it is quality, rather than quantity, which is of first consequence. It should develop facility in systematic and logical reasoning, thus furnishing a general method, as well as a specific means of getting results. The mathematical teacher must be in sympathy with engineering work, and have a just appreciation of its problems and its methods; he must be imbued with the spirit and the ideals of the engineer.—*Abstracted from Science (New York), July 31.*

INDUSTRIAL SECTION

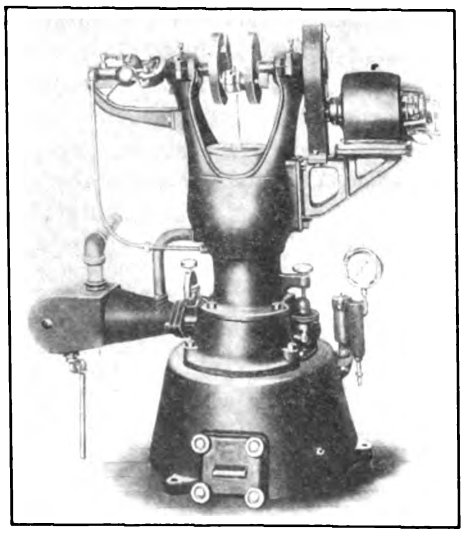
ILLUSTRATED DESCRIPTIONS OF NEW AND STANDARD ELECTRICAL AND MECHANICAL APPARATUS

Vacuum Cleaner.

Many types of vacuum cleaners have been developed in the past few years for all sorts of conditions. For office buildings, hotels, theatres, large residences, etc., no type is so satisfactory as that forming a permanent part of the building, as there is nothing to handle but the light hose and tools.

A pump in the basement driven by a small motor does the work. Special pipes are provided with neat outlets in convenient locations on the various floors. At these points a flexible hose may be attached and the surrounding floors, walls, ceilings, furniture and upholstery thoroughly cleaned and renovated.

One of the most satisfactory of these systems is that supplied by the Palm Engineering Company, of Detroit, Mich., which is herewith illustrated and which can be installed in any building, either old or new, at a low cost and without inconvenience.



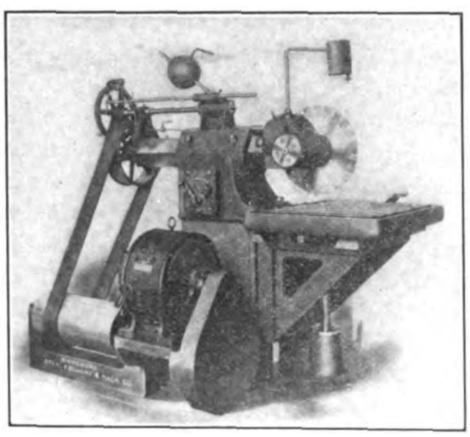
MOTOR-DRIVEN VACUUM CLEANER.

The motor and the pump are of very rugged and substantial construction, so that but little attention is required. The motor is of standard Westinghouse design of one-half-horse-power capacity, and is ample to do all the work required. The pump is of the plunger type, but has a loose-fitting piston. The feature of the system is the means adopted for obtaining the vacuum with this loose-fitting piston. Water is supplied to the cylinder and produces the effect of a tight piston without the friction and wear which would result from the dirt and dust if the piston actually made contact with the cylinder; in all other systems some sort of dust separator is required to prevent the dirt from entering the working parts.

The entire outfit is very compact and substantial and is constructed with the idea that it may be operated by persons with but little knowledge of mechanical devices. It is entirely self-contained and requires no foundation except a good floor.

The Wagner Cold Saw.

The changes which are taking place in machine tools at the present time have the object of greater production with greater ease of control. A majority of these changes are due to the adoption of electric motors for the driving power. The accompanying illustration shows a very good example of the latest development of the Wagner cold saw, manufactured by the Birdsboro Steel Foundry and Machine Company, equipped with the Westinghouse type "S" direct-current semi-enclosed constant-speed motor. The method of mounting makes a most compact unit, which can be located at any convenient point in the shop.



WAGNER COLD-SAW

The cross-feed of the work table, in connection with the vertical movement, enables the work to be brought up to the saw without blocking, except enough to level the casting. This saw is especially designed for small work, such as cutting off sink heads, and may also be used for cutting mitres or bevels, as the head may be turned through any angle desired.

Where the degree of hardness of the material to be cut varies considerably, the peripheral speed of the saw must also be varied. For this purpose variable-speed motors are supplied, permitting the speed to be reduced when cutting high-carbon steel.

A large type of cold saw is also manufactured by the same company, which is built in several sizes up to a fifty-inch saw, capable of sawing through a sixteen-inch rod. These saws are supplied with motor drive, with a chain or belt connection, or may be geared direct if desired.

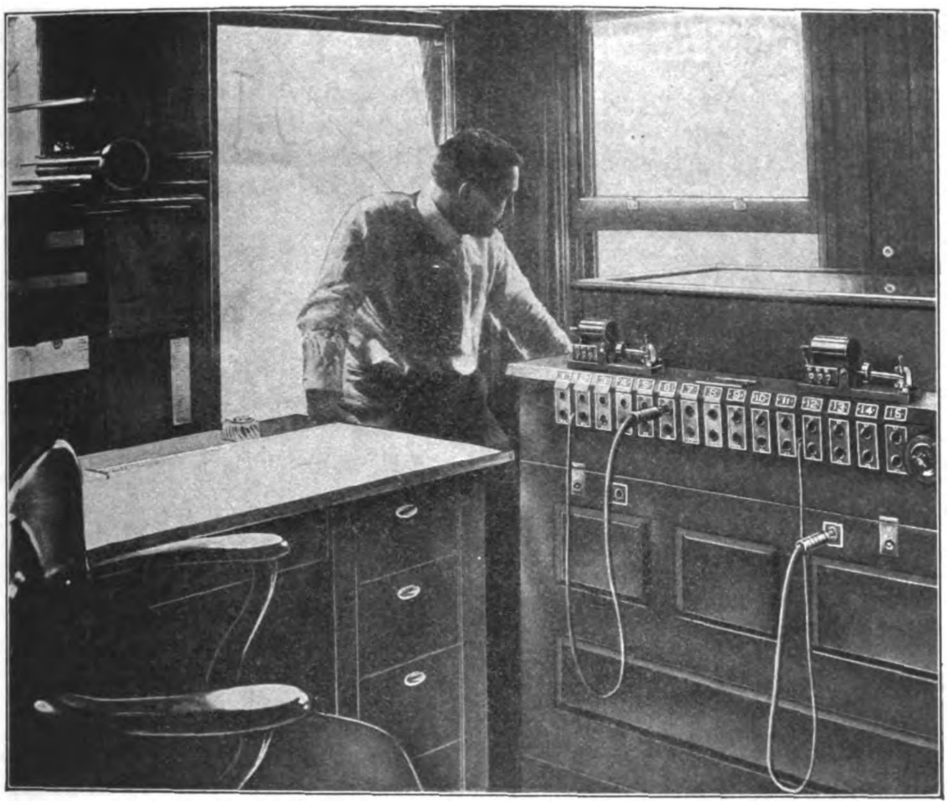
Blake Signals on the Washington, Baltimore & Annapolis Single-Phase Road.

In installing Blake despatchers' signals on a high-voltage, alternating-current, single-phase trolley road, such as the Washington, Baltimore & Annapolis, there were three points that had to be considered which do not enter into an installation on a 550-volt direct-current trolley line:

1. A small amount (about 0.7 ampere) of 550-volt direct current at the despatcher's office for operating the signals.
2. The necessary light at each line signal for night signaling.
3. Would the presence of large amounts of high-voltage, alternating current on the trolley wire and with a rail return, by induction or otherwise, prevent or seriously interfere with the proper operation of the signals?

In the case under consideration the first point was easily settled as there is available at Academy Junction, where the despatcher's office is located, an ample supply of 550-volt direct current. On any road this question could be easily solved by use of a small one-half-horse-power motor-generator set, if 550-volt direct current were not available at the despatcher's office.

For the second question the use of standard railway oil lamps seemed the proper solution for reasons of reliability, economy of maintenance and general practicability. This being settled it was merely a question of deciding upon the proper type of lamp and developing a suitable mechanical connection for it to the signal. Now, in choosing the type of lamp it is



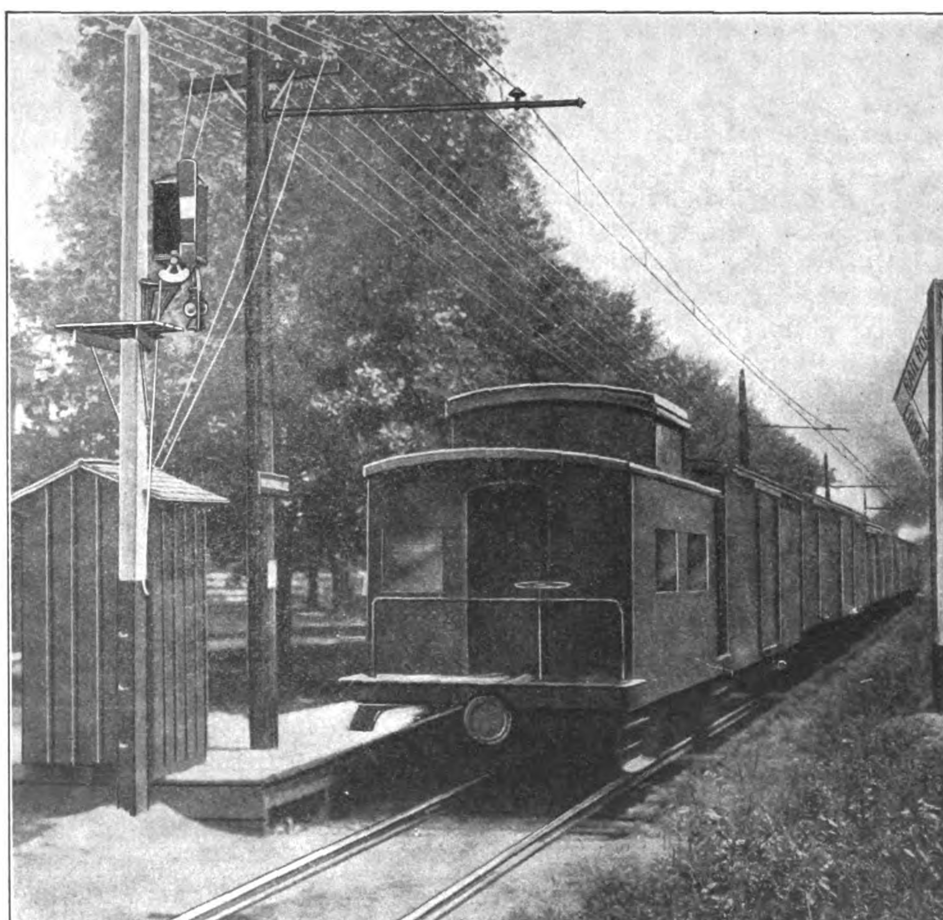
Despatcher's Office, Controlling Blake Signals on the Washington, Baltimore & Annapolis Railway.

to be remembered that the signals are a despatcher's train-order signal and therefore require and have but two positions, namely, "clear" and "stop," the semaphore blade being vertical for the former and horizontal for the latter. Also the semaphore blades on the Blake signal operate in the upper quadrant. On account of there being but two positions it seemed best to use a four-lens lamp, thus doing away with the cumbersome spectacle and additional glassware incident thereto. By reason of the semaphore operating in the upper quadrant it was possible to attach the lamp to the base of the signal suitably and substantially.

The lamp used is a standard four-lens railway switch lamp set upon a substantial and laterally rigid bail or hanger. This hanger is securely pinned to a short, heavy vertical shaft which goes up through the base of the signal and is suspended on a spiral in such a way as to permit of the shaft making a quarter turn. The top of this vertical shaft is also strongly connected with the semaphore shaft, so that the semaphore shaft and hanger shaft turn together, although one in a horizontal and the other in a vertical plane. By using a spiral support for the hanger shaft the weight of the lamp and hanger aids rather than retards the semaphore in going from the "clear" to the "stop" position, and in the event of the breakage of the rod connecting the semaphore shaft and hanger shaft the lamp will, of its own weight, make a quarter turn so as to display a red light. This is on the side of safety and prevents any possibility of the lamp showing a clear signal when the semaphore is at "danger" or "stop" position.

On the Washington, Baltimore & Annapolis a fork type, long-time-burner lamp is used having two green lenses and two red lenses. The hanger is so made that while the lamp is securely set upon it, the lamp itself may be readily removed and replaced, but the lamp can only be put up so that the green lenses show in both directions along the track when the semaphore is in the vertical or "clear" position and the red lenses show in both directions along the track when the semaphore is in the "stop" position. It is physically impossible to set the lamp so that its signal lights are at variance with the position of the semaphore arm. When the semaphore is vertical or "clear" the lamp shows a green light up and down the track. When the despatcher sets the semaphore in the horizontal or "stop" position, as the semaphore arm comes down the lamp makes a quarter turn and shows a red light up and down the track.

The lamps burn constantly and are filled and trimmed twice a week. They are of a standard railway type practically impossible to blow out, and showing a



Blake Signals on the Washington, Baltimore & Annapolis Railway.

steady, bright light visible on tangents for more than a mile.

The third and last point as to whether the signals would operate on a single-phase line could only be satisfactorily and finally settled by putting them up and trying them. It was practically impossible to artificially create for experimental purposes such conditions as would exist on the railroad itself. Several prominent engineers thought that there might be trouble and that the signals would not work. The manufacturers had nothing to go by but the knowledge that they had signals working satisfactorily on the same pole-line with high-tension, three-phase transmission lines, a thorough knowledge of and confidence in the signals themselves and their own opinion as to what probable effect the presence of a large volume of grounded single-phase current would have on the operation of the signals. It came down to the manufacturers having to guarantee at their own risk the reliable operation of the signals under the special conditions existing. This was done, the signals installed on June 24, 1908, which was within eight days from the time the signal line was ready, and the operation of them has, up to date, been absolutely successful without the least hint of trouble or disturbance due to the single-phase trolley line. On the Washington, Baltimore & Annapolis the railroad was willing to and did furnish two No. 10 bare galvanized-iron wires, on glass insulators, for the signal line. While the two wires undoubtedly make a better installation and insure a clearer indication in the despatcher's office, there is no evidence that they are necessary and that the signals would not work as reliably and satisfactorily on one wire as they do in the case of 550-volt, direct-current trolley lines.

Contract for St. Thomas-Toronto Line Awarded.

The contract for the electric transmission line to be built by the Ontario Government from Niagara Falls has been awarded to the McGuigan Construction Company, headed by F. H. McGuigan, formerly general superintendent of the Grand Trunk Railroad, and later with J. J. Hill. The total length of the line to St. Thomas on the west and Toronto on the east is 293 miles. The contract price is $1,270,000. The aluminum cable is to be constructed at Shawinigan, Quebec, and the steel towers in Ontario. The hydro-electric commission has the option of doubling the mileage at the same price.

The Roller-Smith Company.

The Roller-Smith Company was incorporated under the laws of the state of New York with a capital of $100,000 on July 15, with the following officers: President, F. W. Roller; vice-president, F. W. Iredell; secretary, A. A. Whitman; treasurer, D. R. Smith. Directors: F. W. Roller, F. W. Iredell, P. R. Van Wyck, R. S. Taylor, D. R. Smith.

The Roller-Smith Company immediately acquired by purchase all of the properties of the Whitney Electrical Instrument Company, of Penacook, N. H., and of the Switchboard Equipment Company, of Bethlehem, Pa., and assumed all liabilities of both concerns.

It is the intention of the Roller-Smith Company to continue the manufacturing and developing of the lines heretofore manufactured by both of the acquired companies. That this may be done to a greater economic advantage, the company is now erecting in Bethlehem, Pa., a modern factory especially designed for the production of this apparatus. The factory will be completed and machinery installed about November 1, when the present plants of the Whitney Electrical Instrument Company and the Switchboard Equipment Company will be abandoned.

The Roller-Smith Company will manufacture ammeters, voltmeters, ohmmeters, galvanometers, bond testers and circuit-breakers, and such other apparatus as may lie within these general lines. The principal office of the company will be in Bethlehem, Pa., with its sales office at 253 Broadway, New York city, in charge of Machado & Roller, general sales agents.

Mr. Roller, the president of the Roller-Smith Company, has been actively connected with the Whitney Electrical Instrument Company and Machado & Roller for some time. The treasurer, D. R. Smith, has been president of the Switchboard Equipment Company since its organization about three years ago.

The Grinnell Instantaneous Electric Water Heater.

The accompanying illustrations show two adaptations of the Grinnell instantaneous electric water heater, placed on the market by the Grinnell Electric Heater Company, 905 Broad street, Grinnell, Iowa. This heater is made of ordinary pipe and fittings, in which are placed two electrodes. The cold water enters the heater at the bottom, is heated by the electrodes in flowing through, and comes out of the faucet connected with the top of the heater at any temperature desired, the degree of heat being regulated by the flow of water. In Fig. 1 the heater is shown equipped with a switch attachment which turns on both the electric current and the flow of water at the same time. Fig. 2 shows the heater as attached to any bath tub, lavatory or sink. With this arrangement the current is turned on and off at will by a switch conveniently located, while the flow of water is regulated by the ordinary faucet.

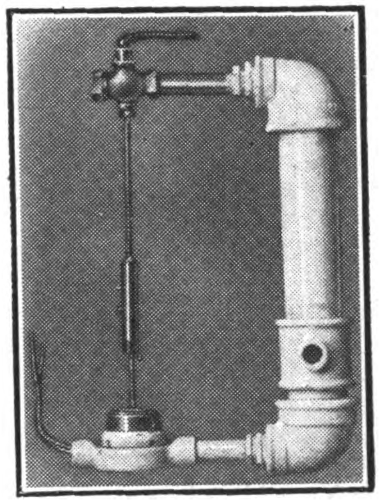


Fig. 1.—Instantaneous Water Heater in Main Pipe Line.

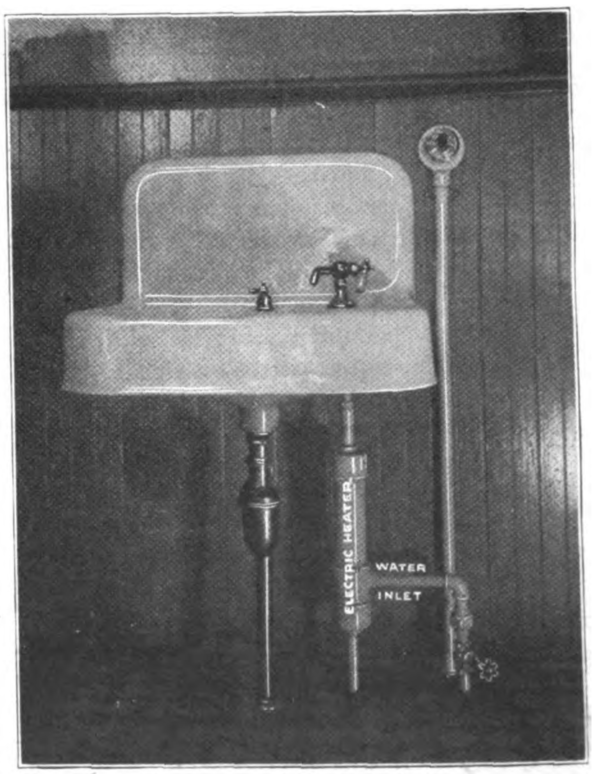

Fig. 2.—Grinnell Instantaneous Water Heater in Water Inlet to Wash Basin.

The company states that careful tests show that one kilowatt-hour will raise ten gallons of water 46.5 degrees Fahrenheit. The heaters are manufactured in sizes from one kilowatt up to any capacity desired.

Illumination of a Railroad Station.

The Union Station at Schenectady, N. Y., besides being one of the most beautiful on any of the New York Central Lines, has been pronounced by experts to be one of the best lighted depots in the country, and the same opinion is voiced by all who have seen the station illumination. When the lighting installation was under consideration careful attention was paid to the lighting units from an esthetic as well as the utilitarian standpoint, and as a result they harmonize well with the gray marble finish of the station interior.

The main waiting room is lighted by General Electric high-current arc lamps equipped with concentric diffusers and opal shades, there being three fixtures suspended from the ceiling and three eight-ampere arc lamps in each fixture. Each lamp is operated in multiple from the alternating-current, sixty-cycle supply circuit. As auxiliaries to the main lighting units, incandescent lights with frosted globes are supported in neat appearing fixtures on the side walls.

Although the arc lamp shown in Fig. 1 is not of the type used in this installation, the illustration will serve to show the relative positions of the diffuser and shade. The lower shade of light opal glass serves to direct the greater portion of the light against the under side of the porcelain covered metal reflector which, it will be noticed, is slightly cone shaped and corrugated. The corrugations serve to thoroughly diffuse the light, the rays being directed outward and downward at every conceivable angle. The resulting illumination is soft and restful, and the light penetrating to all parts of the room eliminates harsh and unnatural shadows.

Comparing this method of lighting with direct lighting, *i. e.*, with arc lamps without diffusers, the consensus of opinion among engineers and architects is that it is by far the better. Although the intensity of the illumination with this method is relatively quite low, it is easier to read or to see any object in the room, and the general effect is more restful than with direct illumination.

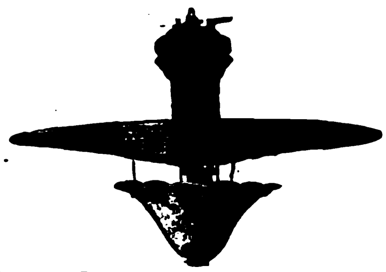

FIG. 1.—DIFFUSING CEILING REFLECTOR.

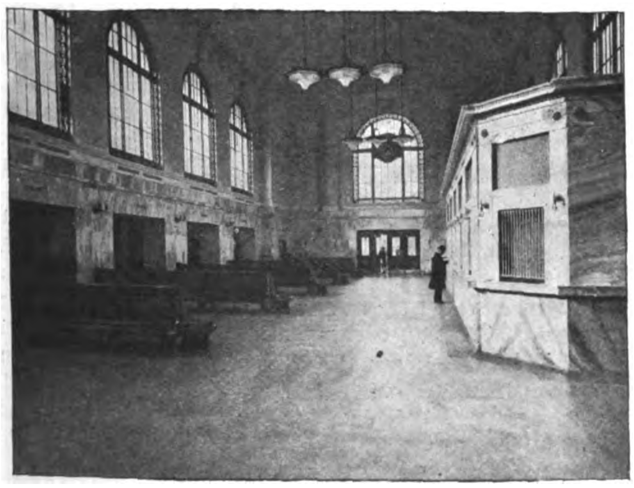
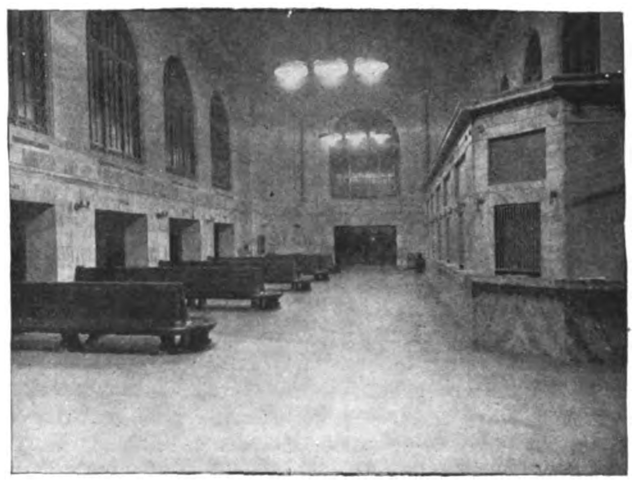
The accompanying illustrations showing the lighting of the station by day and by night, while giving a general idea of the installation, fail to show the true beauty and effectiveness of the illumination. The following tabulation of data is of interest and may serve as a basis of comparison with other installations:

Length of room..........	103 feet
Width	44 feet
Area	4,532 square feet
Number of arc lamps.....	9
Watts per lamp..........	620
Total kilowatts	5.58
Watts per square foot....	1.22
Height of lamps from floor	23.5 feet



DAYLIGHT ILLUMINATION OF UNION STATION, SCHENECTADY, N. Y.



LIGHTING WITH CEILING DIFFUSERS, UNION STATION, SCHENECTADY, N. Y.

Ceylon Rubber Cultivation.

United States Consul E. A. Creevy, of Colombo, has submitted a report upon the rubber industry of Ceylon, which shows to what extent these new sources compete with Brazil and South Africa. The cultivation of Para rubber in Ceylon dates back to experiments made at the Government Botanical Gardens in 1876. The acreage planted is being rapidly increased, and the estimate of planting for 1908 is 10,000 acres. One hundred and twenty acres will come into bearing this year.

Although the experiments in growing rubber had been attended with success from the first, the industry was not seriously considered by planters until about ten years ago. Even then plantings were small and doubtless would have continued so had not the price of tea fallen appreciably. The development of the automobile, with the consequent demand for rubber tires, so increased the price of rubber that the Ceylon planters took up its cultivation in earnest. The returns for the year 1904 showed 25,000 acres planted, with 600 acres bearing; for 1907, 150,000 acres planted, with 2,500 acres bearing. These figures are approximate only, as tea and cocoa are interplanted with rubber; but if the present prices of rubber are maintained it is probable that the tea and cocoa will be taken out.

It has been estimated by competent authorities that the total amount expended to date on rubber growing in Ceylon is about $9,000,000. It is probable that there are 250 Europeans and from 75,000 to 100,000 coolies engaged in the care of the plantations.

Records of export of Ceylon-grown rubber show that in 1904 it was thirty-five tons; in 1907, 397.2 tons, and from January 1 to May 11, 1908, it was 113.16 tons. London is the chief market for Ceylon rubber, but exports to Antwerp and New York are growing. As the native labor is cheap and furnishes the principal factor in determining the cost, there is said to be less chance of the industry in Ceylon becoming unprofitable through a fall in price than in Brazil or on the Congo.

Current Electrical News

DOMESTIC AND EXPORT.

POWER COMPANIES MERGE—The competition between the Roanoke (Va.) Railway and Electric Company and the Roanoke Water Power Company has been ended with the merger of the two companies. The Roanoke Railway and Electric Company announced that it had bought the Roanoke Water Power Company, which belonged to W. N. Camp, a Florida magnate, and his sons. The Camps recently secured a contract for furnishing the city of Roanoke street lights for a period of years, underbidding the older concern, which previously had the field to itself. The purchase price was not made public. The water power company has a large plant on the Roanoke River, three miles below the city.

NEW INDIANA LIGHT AND POWER COMPANY—Articles of association of the Indiana Lighting Company have been filed at Indianapolis, Ind. The capital stock is $4,500,000. The directors are Franklin L. Babcock, Anthony N. Brady, Charles F. Dietrich, Frank S. Hastings, James P. Lee, Samuel T. Murdock, Henry C. Paul, Albert Tag and James N. Wallace. The company is authorized to supply light, heat and power to Fort Wayne, Bluffton, Montpelier, Anderson, Lafayette, West Lafayette, Logansport, Peru, Wabash, Decatur, Geneva, Crawfordsville, Lebanon, Thorntown and Frankfort, in Indiana, and to Lima, Wapakeneta, Celina, St. Mary's, Greenville, Fort Recovery, North Mercer and Coldwater, in Ohio, and to other villages and towns in proximity to the cities and towns named.

LARGE STEEL CAR PLANT TO BE BUILT IN DELAWARE—It was announced on August 11 at the offices of the Harlan & Hollingsworth Corporation, Wilmington, Del., that the local concern and the Bethlehem Steel Company had been consolidated for the purpose of building in Wilmington a plant for the manufacture of steel passenger coaches and all kinds of steel freight cars. The name of the new company has not been determined; neither has the capitalization been announced. The announcement followed a visit of Charles M. Schwab, president of the Bethlehem Steel Company, and the directors of that concern to Wilmington. The Harlan plant at Wilmington will be rebuilt and enlarged and the largest car shops in the country erected. It is estimated that from twelve to fifteen thousand men will be employed. Work on the plant will begin at once. The Bethlehem Steel Company will make the steel and the cars will be erected in the local plant.

TOLEDO RAILWAY AND LIGHT COMPANY—Albion E. Lang has been chosen to succeed H. A. Everett as president of the Toledo (Ohio) Railway and Light Company by the directors of the company. Warren T. Bicknell, of Cleveland, was elected chairman of the board of directors, succeeding Mr. Lang, the new president. The directors present were: E. W. Moore, of Cleveland; Dr. Demers, of Quebec; W. E. Hutton, of Cincinnati; Barton Smith, A. E. Lang, Spencer D. Carr, J. K. Secor and L. E. Beilstein, of Toledo; W. E. Halsey, of Louisville, Ky., and George Hafer, of Cincinnati. The troubles of the traction company are being worked out gradually. After the appraisement of the property a new corporation will be organized, which will take in the Toledo Railway and Light Company, the Toledo and Western, the Maumee Valley and Toledo and the Ottowa Beach & Northern Traction lines. Each of these companies will go into the new company at the appraised value. The new company will be a $20,000,000 or $25,000,000 corporation. Following this organization will come the application for a franchise.

MILWAUKEE MEN PURCHASE ELECTRIC ROAD—All of the property of the Winnebago Traction Company, Oshkosh, Wis., has been sold at auction for $950,000. This includes the franchises, easements, rights, real estate, tracks, rolling stock, power plants and all other equipment. The purchasers are Oliver C. Fuller, Fred. C. Best and Russell L. Smith, all of Milwaukee. Mr. Fuller is president of the Wisconsin Trust Company, Mr. Reed is its secretary and Mr. Smith is the assistant secretary. The sale was made to the individuals named and not as representatives of the trust company. It is the purpose to reorganize the Winnebago Traction Company with Milwaukee and Oshkosh capitalists as stockholders, officials and directors and with Clement C. Smith, of Milwaukee, as president. An association of interests of the traction company and the Eastern Wisconsin Railway and Light Company will be formed within a short time. The extension of the Omro interurban line to Berlin is practically assured. The Oshkosh lines will be overhauled and repaired and changes made. J. P. Pulliam, the present superintendent of the traction company, will remain in charge as active manager. Only one bid was made, which was $50,000 more than the amount stipulated by the court as the minimum amount which would be approved by the court. The sale was made under the terms that at least $125,000 in cash be paid, bonds of the company being acceptable for the balance. A check for $25,000 was deposited by Mr. Fuller in advance, he being the actual bidder.

CONSOLIDATION OF TELEPHONE COMPANIES IN PENNSYLVANIA—The merging of the Consolidated Telephone Company of Pennsylvania and the American Union Telephone Company, of Harrisburg, has been completed. The Consolidated Company has about 20,000 instruments connected with forty-seven exchanges in the territory extending from Philadelphia to Scranton, Pa., east of the Susquehanna River. This company has a capital of $4,000,000. The American Union Company occupies the territory embracing Central Pennsylvania from Philadelphia to Pittsburg, Buffalo and Erie. It has 187 exchanges in the larger cities and towns of its region with a total of 51,000 telephones attached to its lines, and has a capital of $25,000,000. The merged company will have connections at Trenton, N. J.; Buffalo, Binghamton, Utica, Rochester and other cities in New York state. The following officers have been elected: President, Ellis L. Orvis, Bellefonte; vice-president, F. D. Holck, Harrisburg; secretary and treasurer, S. R. Caldwell, Harrisburg. These officers hold the same positions in the American Union company. Directors: M. Houck and Mr. Orvis, and the following: S. P. Light, Lebanon; James B. Krause, Williamsport; Lyman D. Gilbert, Harrisburg; B. F. Meyer, Harrisburg; James Kerr, Clearfield; J. L. Spangler, Bellefonte; Charles West, Allentown; Timothy S. Clark, Williamsport; Asbury W. Lee, Clearfield, and William Jennings, Harrisburg. With the exception of Mr. Houck and Mr. West, these directors are all on the board of the American Union company.

ELECTRIC LIGHTING.

ST. CATHARINES, ONT.—The city council has passed a by-law canceling the franchise of the Falls Power Company.

TARBORO, N. C.—The town commissioners have authorized J. A. Weddell to purchase another dynamo for the electric light plant.

OGDEN, UTAH—Work on the great Devil's Gate power plant has been started. The cost of the plant will be upward of $350,000.

LAWRENCE, KAN.—Nearly $1,000 will be spent by the University of Kansas installing a permanent system of lighting on the grounds of the campus.

BUFFALO, N. Y.—J. J. O'Leary has been engaged to draw up plans and specifications for the proposed electric lighting plant to be installed at the city and county hall.

DURHAM, N. C.—The Durham Traction Company has been awarded a five-year street lighting contract by the board of aldermen at the rate of $85 per lamp per annum.

HAZLETON, PA.—The Consumers' Light and Power Company, of Hazleton, has been awarded the contract for lighting the streets for a term of ten years at a rate of $55 per light.

FLORENCE, COL.—The Eastern Colorado Electric Power Company, which is establishing a generating plant near Glenwood

Springs, has filed on the undeveloped water of Grape Creek. The purpose of the company is to furnish power for several mills and smelters in this county.

ESCANABA, MICH.—Escanaba's new enclosed arc lights have been placed in commission. Current is furnished from the plant of the Escanaba Power Company on the Escanaba River.

SIOUX FALLS, S. D.—Scotland has decided to have electric lights, and a committee has been inspecting the systems in the surrounding towns. Bids from private concerns will be invited.

MORRISTOWN, N. J.—The Morris & Somerset Electric Company has taken formal possession of the Public Service Corporation's electric plant, the former company having leased it for ninety-nine years.

ELLWOOD CITY, PA.—The council has decided to settle the question of building a new power plant here by allowing the people of the borough to vote on the matter. Plans for a $40,000 plant have been submitted.

ELMIRA, N. Y.—The Wadhams & Westport Electric Light and Power Company, which has a plant at Wadhams, on the Boquet River, and another on the Black River, is installing an additional dynamo to care for its lighting load.

ELSINORE, CAL.—At a meeting of the trustees the committee on electric lights recommended the placing of fifty lights on various streets about town. The electric light company offered to furnish the city lamps to the amount of 1,200 candle-power for $50 a month. The proposition was accepted.

BATAVIA, N. Y.—Seth W. Warren has been appointed permanent receiver of the Batavia Light and Power Company, with a bond of $20,000. The company is solvent, having assets of about $20,000 and few liabilities. The advent of natural gas and Niagara power in Batavia is the cause of the receivership.

ALBION, N. Y.—The Public Service Commission, Second District, has approved of the petition of Sanford P. Church, receiver of the Albion Power Company, for authority to issue $20,000 in receivers' certificates, the proceeds to be used in improving the company's plant in Albion, as required in a recent order of the commission.

LORAIN, OHIO—The special committee of council on the city lighting plant presented an ordinance to the city council appropriating $250 from the board of public service contingent fund for the purpose of employing an engineer to procure data on the cost of constructing a lighting plant. The resolution was passed by a unanimous vote.

GLENS FALLS, N. Y.—The Public Service Commission, Second District, has granted the Kanes Falls Electric Company permission to construct an electrical transmission line in the towns of Fort Ann and Kingsbury, Washington County, and Queensbury, Warren County, and approval of the exercises of right and privileges under these franchises.

FRANKFORT, KY.—The Capitol Commission has signed contracts with Joseph McWilliams, of Louisville, for the erection of the new power-house and the purchase of the electrical supplies for the new capitol. The contract provides that the work must be completed within 130 days after the date of signature, and provides for an outlay of $85,521.

TIFFIN, OHIO—The Tiffin Edison Electric Illuminating Company, of Tiffin, has increased its capitalization from $50,000 to $150,000, because of extensive improvements about to be made at the plant. The buildings will be added to, and new equipment put in. The company has taken a large number of contracts to furnish local manufactories with electric power.

SCRANTON, PA.—An ordinance has been introduced in the city councils providing for the placing under ground of all electric wires in Scranton, including those of the fire alarm and police telegraph systems, and excepting only the trolley wires of the street railway company. The network of overhead wires in some of the alleys and narrow streets has been a hindrance to the work of the fire department..

PANGUITCH, UTAH—A company has been formed here to put in an electric plant about one and a half miles up the Panguitch Creek. It has a capital of $15,000. The officers are John Houston, president; Thomas Haycock, vice-president; Clem Tebbs, secretary; R. Judds, treasurer. Directors, J. J. Page, J. G. Spencer and H. P. Ipsen. The building of the plant will begin as soon as contracts are awarded.

PORT ARTHUR, TEX.—The Port Arthur Water Company is preparing to greatly enlarge its capacity for electric lighting and power. This is made necessary by the demands on the company. The water company now has three sets of generators, two driven by 150-horse-power engines and one by a 100-horse-power engine. The new addition now being added consists of a 500-horse-power engine and generator.

SOUTHOLD, N. Y.—At the annual meeting of the Southold Lighting Company the following directors were elected for the coming year: Dr. Joseph H. Marshall, Thomas Farley, Lewis W. Korn, E. D. Cahoon, Frederick C. Williams, S. Lester Albertson, Frederick K. Terry. The directors elected the following officers: President, Dr. Joseph H. Marshall; vice-president, Frederick C. Williams; secretary, Frederick K. Terry; treasurer, Lewis W. Korn.

COLORADO SPRINGS, COLO.—Alderman Carl Albin has introduced a resolution in the city council that the city at once take steps to secure the water rights granted to Irving Howber and associates to generate power for a Colorado Springs-Cripple Creek electric line, claiming that their successors had failed to keep the terms of the franchise. The resolution characterizes this as the first step toward establishing a municipal lighting plant.

DAYTON, OHIO—The county commissioners have awarded the contract for furnishing electric power for the new county infirmary building to the Dayton Lighting Company. The lighting company will furnish the power at an annual cost of $1,900, the contract to take effect as soon as the service begins. The commissioners formerly intended to install their own plant, but irregularities in the plans and specifications resulted in all bids being thrown out.

CHATEAUGAY, N. Y.—The Up-State Service Commission has acted favorably upon the petition from the Chateaugay Electric Light and Power Company, which asked for consent to transfer its franchise, works and system to the Chasm Power Company. The Chateaugay Electric Light and Power Company has been in business for about eleven years, but with the advent of the Chasm Company was unable to compete with the latter in the matter of giving a twenty-four-hour service.

DANIELSON, CT.—A force of men is at work on the construction of a dam and power plant for the Danielson Cotton Company across the Quinebaug River, a half mile above Cotton Bridge. The site is about five miles from Danielson in a northwesterly direction. The dam will be about 250 feet long and twelve feet high. The power developed will be used in the power plant to be erected nearby. Power will be transmitted over a high-tension line to Danielson for the operation of the machinery in the new addition the cotton company has under way.

MARIETTA, GA.—The Georgia Manufacturing and Public Service Company, a half-million-dollar corporation which supplies the city of Marietta with electric light and water, has been placed in the hands of a receiver, an involuntary petition for bankruptcy having been filed against it by the Atlanta Machine Works, Sciple Sons, and a local paper. The receiver appointed is James T. Anderson, a banker of Marietta. He has been ordered to take charge of the electric light and water-works plant of the company and to continue the operation of them until the further order of court.

HAMILTON, OHIO—Frederick G. Mueller, an architect of Hamilton, is engaged in drawing up plans for a new electric power plant to be constructed and operated by the Hamilton Hydraulic Company and managed by T. A. Jones, superintendent of the Harding Paper Mill, of Excello, Ohio. The new power plant will be owned by the Harding estate, of which Congressman J. Eugene Harding, of Middletown, is a member. Definite plans for the new structure have not yet been completed. The building will be about eighty feet square. Building will begin as soon as plans have been completed.

ALBANY, N. Y.—The Up-State Public Service Commission has granted permission for the operation of a second electric light company in Bath, Steuben County, and surrounding villages and towns upon the ground that the existing company has failed to keep up to the needs of the locality and consequently is entitled to little consideration when it seeks to exclude competition. The opinion, written by Chairman Stevens, states that no general rule can be formulated which will indicate with precision when a new lighting company may be permitted to do business in a field already occupied by another company, and that the circumstances and conditions prevailing must control the decision.

ELECTRIC RAILWAYS.

MONROVIA, IND.—E. M. Bowman is securing the necessary right of way for a trolley line from Mooresville to Cloverdale, passing through Monrovia.

TACOMA, WASH.—The Pacific Traction Company will complete its new line to Steilacoom, beginning work within a few weeks, and having the line in operation before winter.

ATHENS, GA.—The Athens Electric Railway Company will at once put in extra machinery for the generation of 1,000 horse-power in addition to the 3,000 horse-power now available and in service.

PLAINVIEW, TEX.—The City Railway Company has secured a franchise for the construction of an electric street railway in this city. Work will be commenced within a few months, according to C. D. Lovelace.

WATERBURY, CT.—The railroad commissioners have approved of the construction of the Connecticut Company's new trolley line between Waterbury and Thomaston, and the line has been thrown open for public travel.

DES MOINES, IOWA—The Iowa Construction Company has filed articles of incorporation with the secretary of state. The company will build an electric line from Perry to Waterloo, through Ames, Eldora and other towns. Its capital is $100,000.

NEW HAVEN, CT.—The railroad commissioners have approved the petition of the New York, New Haven and Hartford Railroad Company to allow the new trolley line between Hartford and Middletown to pass through the town of Griswoldville.

HUTCHINSON, KAN.—The People's Water, Light and Power Company, of which Emerson Carey is president and general manager, purposes building an electric line extending east and west from Hutchinson, and having a total length of about sixty miles.

BUFFALO, N. Y.—The Buffalo Southern Railway Company is completing its plans for a new line of electric railway from Seneca street to East Aurora along a private right of way for twenty miles. It is estimated that the work will cost upward of $500,000.

NORWICH, CT.—The contract for building the Willimantic and South Coventry trolley has been awarded to Lathrop & Shea, of New Haven, and work will be started within a few weeks. The line is to run from Norwich to Lake Wamgumbaug, a distance of about six miles.

INDIANA, PA.—The directors of the Indiana Street Railway Company have let the contract for the extension of their line from Homer City to Josephine, a distance of five miles. As soon as the right of way is secured the contract for an extension to Blairsville will be awarded.

OREGON, MO.—Active construction work has begun on the Oregon Interurban Railway. The contract is in the hands of M. A. Wagoner, of Leavenworth. The road will connect Oregon, Mo., with the Chicago, Burlington & Quincy Railroad at a point about four miles distant.

HELENA, ARK.—Several capitalists are negotiating with the Helena board of trade for the construction of a street car line in that city. The promoters of the enterprise propose that business men of Helena shall subscribe for one-third of the money necessary to finance the road.

WEST CHESTER, PA.—At a meeting of the directors of the proposed trolley road between West Chester and Pottstown it was decided to construct and equip the road at a probable cost of $200,000, and the contract for construction has been awarded to Charles F. Goldstrohm, of Pittsburg.

LOCKNEY, TEX.—Consideration is being given in this section to a proposed interurban from Amarillo, *via* Tulia and Plainview, through Lockney, Floydada, Emma and Lubbock. W. W. Jones, a farmer of Plainview, who is representing Ohio capital, is urging that the towns along the proposed route give a bonus of $25,000.

PATERSON, N. J.—At a meeting of the directors of the North Jersey Rapid Transit Company, formed to build an electric road from Suffern, N. Y., to Paterson, N. J., the following officers were elected: President, William A. Barbour; vice-president, Malcolm R. McAdoo; secretary and treasurer, H. H. Parmalee. The company is capitalized at $2,000,000. Construction will be started at once.

LOS ANGELES, CAL.—The Pacific Electric Railway Company is expected to begin grading soon from Santa Ana to the beet-sugar factory that is in process of construction two miles from that city on the Newport Beach route. It will be the first section of a trolleyway to run to the sea. The Santa Ana council has granted a fifty-year franchise for the part within municipal limits, and the necessary right of way has been obtained.

NAPOLEON, OHIO—The filing of a $250,000 mortgage here by the Grand Rapids Electric Railway Company to the Cleveland Trust Company to secure funds for use in the construction of the line, has revived hopes that the old Coldwater right of way will be utilized. The proposed route is from Alpena to Grand Rapids and from Grand Haven *via* Grand Rapids south through Michigan and the Ohio counties of Williams, Fulton, Henry and Wood to Fostoria.

BOONVILLE, MO.—Albert Parker, formerly mayor of Topeka, is president of a company incorporated to build an electric railroad in southern Missouri. The company is known as the Kansas City, Ozark & Southern Railroad. The present purpose is to build a line from Mansfield to Ava, fifteen miles, in Douglas County. The line has been graded, and it is expected that it will be completed within four months. There is not now a mile of railroad in Douglas County.

SEATTLE, WASH.—The Seattle Electric Company has begun an extension of its West Seattle lines, and will continue the road from its present terminus near Luna Park around Alki Point for about one and one-quarter miles. The cost of the new work will be $28,000, and about 100 men will be employed. Forty new cars have been ordered by the electric company and are now under construction in the East. They are due to arrive in Seattle within sixty days.

MAUCH CHUNK, PA.—The Carbon Transit Railway, which runs through the Mauch Chunk and over the mountain into Lehighton, familiarly known as the Carbon Street Railway, has been sold to a syndicate composed of J. M. Wolff and J. F. Geiser, of Waynesboro; L. H. Mountney, of Mauch Chunk, and C. H. Latta, of Bethlehem. Messrs. Wolff and J. F. Geiser are concerned in the Waynesboro & New Castle Railway, and Mr. Latta is interested in the Stroudsburg & Water Gap Railway.

McKINNEY, TEX.—John S. Heard, J. P. Crouch, S. D. Heard, L. A. Scott, F. B. Pope, J. L. Lovejoy, J. Y. White, R. L. Waddill, J. P. Burrus and George Wilcox, all of this city, have organized the Fort Worth, McKinney & Bonham Traction Company, with a capital stock of $25,000, for the purpose of making surveys, getting estimates and full investigation as to the merits of a road from Fort Worth to Bonham *via* McKinney. If the engineers report favorably the charter will be applied for and the capital stock will be increased to the proper amount.

TOPTON, PA.—Philadelphia capitalists are interested in the building of a proposed trolley line to connect Lyons and Macungie. The line as contemplated, while not to be an extension of the lines reaching those places, will be the closing link for continuous trolley service along the East Penn, and will pass through Bowers, Topton, Hancock, Mertztown, Shamrock and Alburtis along the south side of the railroad. Should the road be built, the different towns along the line may obtain the additional convenience of electric lights. The right of way is being obtained and progress is expected to be made rapidly.

COLORADO SPRINGS, COL.—The Kansas-Colorado Electric Railroad and Power Company has broken ground for its line connecting Canyon City with Pueblo *via* Turkey Creek at a point twenty-five miles south of Colorado Springs, and nine miles west of Pueblo. The line will be extended to Colorado Springs, where connection with Denver will be made over the Denver & South Platte electric line. The road will ultimately follow the Arkansas Valley across the Kansas border, furnishing also light and power as well as water for irrigation. W. J. Coursin, of Pittsburg, has been awarded the contract for construction of the Denver & South Platte Railroad Company's twenty-five-mile electric line from Littleton to Roxbury Park in the western part of Douglas County. Littleton, five miles out, is already connected with Denver. The road may be completed to Colorado Springs before June 1, 1909, as it is the plan to make Roxbury Park a summer resort.

PERSONAL MENTION.

MR. GASTON LACOMMI, an electrical engineer with a laboratory in Brooklyn, N. Y., is said to have devised a wireless telegraph sending apparatus capable of transmitting four messages at the same time. It is understood that Mr. Lacommi utilizes a transformer giving four different frequencies.

MR. HENRY FARMAN, the French aviator, was entertained by Thomas A. Edison at the Orange, N. J., laboratories last week, and treated to a moving-picture exhibit of his æroplane flights at the Brighton Beach race-track. Among those present were Mrs. Farman, Paul F. Mottelay, Charles M. Manly and Mrs. Manly, Albert C. Triaca and Mrs. Triaca, Robert Whitaker and William J. Hammer, who arranged the party.

MR. LOUIS WINDMÜLLER is the author of a very interesting article entitled "Reminiscences of Financial Problems" in the August *Forum*. Mr. Windmüller begins with an account of conditions in 1857, when all classes of industrial companies went to the wall and the steam railroads were particularly affected. The story takes us through the stormy days of the Civil War and the panic which followed, and reviews the runs on the savings banks in 1873. Each of the panics which have occurred since that time is taken up, and the reasons for them and the lessons taught are analyzed in a philosophic and masterly fashion which makes the article of great value at this particular time.

OBITUARY NOTE.

DR. WILLIAM M. HABIRSHAW, chairman of the board of directors of the Habirshaw Wire Company, died at his summer residence at Saratoga, N. Y., on August 16. Dr. Habirshaw had been an invalid for several years, and about three months ago suffered a relapse which totally confined him to the house. For some time he had been under the constant treatment of a physician, and was accompanied everywhere on his travels by a trained nurse. Early in the present year, attended by his nurse, he took a prolonged trip through Europe, returning in June. Shortly after this he went to Saratoga, but instead of improving, suffered a stroke of apoplexy about two weeks ago, from which he never rallied. Dr. Habirshaw was recognized as one of the most skilful analytical chemists in the country. He was a pioneer in the development of cable-making machinery and in the production of insulated wires and cables. At one time he served the Peruvian Government as official chemist, and his professional services were engaged from time to time by the New York State Agricultural Society, the New York Produce Exchange and other important commercial organizations. Dr. Habirshaw was widely known in the electrical field, and had a host of friends and acquaintances both here and abroad. Dr. Habirshaw was buried from St. Thomas's Episcopal Church, New York city, Wednesday, August 19.

DATES AHEAD.

Ohio Electric Light Association. Annual convention, Put-in-Bay, Ohio, August 25-27.

Colorado Electric Light, Power and Railway Association, Glenwood Springs, Col., September 16-18.

Arkansas Association of Public Utilities Operators. First annual convention, Little Rock, Ark., September 17-18.

Old Time Telegraphers' and Historical Association, and Reunion of Military Telegraphers, Niagara Falls, N. Y., September 16-18.

Illuminating Engineering Society. Annual convention, Philadelphia, Pa., October 5-6.

American Street and Interurban Railway Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Accountants' Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Claim Agents' Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Engineering Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Manufacturers' Association. Annual convention, Atlantic City, N. J., October 12-16.

American Electrochemical Society. Fall meeting, New York

LEGAL NOTE.

TELEPHONE—EXCESSIVE CHARGES—RECOVERY—The Supreme Court of Illinois held, in the case of The Illinois Glass Company *vs.* Chicago Telephone Company, that a customer of a telephone company cannot recover excessive charges for services voluntarily paid without fraud, mistake of fact or other ground for annulling the contract. It appeared that in January, 1889, an ordinance of the city of Chicago authorized the appellee to construct and operate telephone lines in the city for a period of twenty years. It was required to file with its acceptance of the ordinance a schedule showing the rates then charged for telephone service, and was prohibited from increasing to subscribers the rates so established. The appellee accepted the ordinance and filed a schedule showing that it charged $125 per year for a business telephone within the district where the appellant was located. The appellant contracted for a telephone at that rate and used it for some years. In time the telephone grew less efficient, and upon complaint of that fact being made by the appellant company, the appellee suggested that if the former would procure an improved telephone equipment known as a "metallic circuit" it would have a much better service, which would cost it $50 a year additional. In October, 1897, the appellant entered into a contract such as suggested and paid that rate for five years, when it brought suit to recover the excess over the rate fixed by the ordinance. The court held that although the appellee could not legally require payment of more than $125 per year, yet that the larger sum had been paid, without fraud, mistake of fact or other ground for annulling the contract, and that the court below did not err in directing a trial for the appellee.

ELECTRICAL SECURITIES.

There was a slight reaction in the stock market last week, with some of the prominent industrials falling off a few points. The copper industry appears to be improving, with general improvement, also, throughout the electrical field. Railroad freight is becoming more in evidence, and the fine weather augurs well for the harvesting of bounteous crops.

Dividends have been declared upon the following electrical securities: American Telegraph and Cable Company; regular quarterly dividend of 1¼ per cent, payable September 1. Columbus (Ohio) Railway Company; regular quarterly dividend of 1¼ per cent on the common stock, payable September 1 to stock of record August 15. Grand Rapids (Mich.) Railway Company; quarterly dividend of 1 per cent on the common stock, payable September 1. Whatcom County (Wash.) Railway and Light Company; regular semiannual dividend of 3 per cent on the preferred stock, payable September 1. Northern Texas Electric Company; regular semiannual dividend of 3 per cent on the preferred stock, payable September 1 to stock of record August 17.

ELECTRICAL SECURITIES FOR THE WEEK ENDED AUGUST 15.

New York:	Closing.

INDUSTRIAL ITEMS.

THE WESTINGHOUSE AIR BRAKE COMPANY, Pittsburg, Pa., has ready for distribution its instruction pamphlet No. 5,034. This is devoted to the type L triple valve.

THE HOLOPHANE COMPANY, New York city, in the July issue of "Holophane," describes and illustrates the enameled Holophane manufactured under the Zalinski patents.

THE WEBER GAS ENGINE COMPANY, Kansas City, Mo., is distributing a bulletin describing the Weber down-draft suction gas-producer. Copies of this bulletin will be furnished to those interested upon request.

THE NORTHWESTERN EXPANDED METAL COMPANY, Old Colony Building, Chicago, Ill., is distributing a folder giving considerable information of value to architects and engineers, concerning expanded metal for concrete and steel construction.

THE AMERICAN SPIRAL PIPE WORKS, Chicago, Ill., is publishing a handsome catalogue devoted to spiral riveted pipe. A number of interesting illustrations are given, showing applications of this pipe in various hydraulic and engineering enterprises.

THE F. BISSELL COMPANY, 226-230 Huron street, Toledo, Ohio, has ready for mailing some new information concerning Bryant plug cutouts, Perkins "New Wrinkle" sockets, "Security" motor-starting panels, and "Cushing" stage-lighting specialties.

THE GOLDSCHMIDT THERMIT COMPANY, New York city, has under construction a new machine shop and foundry occupying a space thirty-four by ninety feet, just back of its present factory in Jersey City, N. J. This is to be fitted up for the purpose of handling to better advantage the extensive repair work which is now being carried on.

THE JEFFREY MANUFACTURING COMPANY, Columbus, Ohio, has published a handsome bulletin, No. 25, devoted to its machinery for handling coal and ores. This bulletin is replete with interesting illustrations showing applications of the Jeffrey company's apparatus, and will be found of value by all who are interested in machinery of this nature.

JOHN L. GLEASON, Jamaica Plain, Mass., is distributing a new bulletin describing "Fancleve" fittings for flexible armored cables, switch-boxes for old work, and the No. 750 cutout cabinet for old or new work. These fittings are especially adaptable for contractors, engineers and architects, and the literature will be sent to those interested upon request.

THE BRISTOL COMPANY, Waterbury, Ct., has ready for distribution some interesting information concerning recording voltmeters, recording ammeters, recording wattmeters for all ranges in both direct and alternating current, recording shunt ammeters for all ranges of direct current, portable recording voltmeters, pressure recording gauges and patent steel belt lacing.

THE C. W. HUNT COMPANY, West New Brighton, N. Y., is distributing pamphlet No. 081. This describes and illustrates coal-handling machinery, conveyers, industrial railways and stevedore rope. The bulletin, however, takes up only a portion of the apparatus manufactured by the C. W. Hunt Company, and is an introduction to the general line of labor-saving machinery which the company produces.

DOSSERT & COMPANY, 242 West Forty-first street, New York city, has published its annual catalogue devoted to Dossert solderless connectors, cable taps and terminals. Since issuing the last catalogue, the National Electrical Code has been amended to permit the use of an improved mechanical joint without solder. Dossert joints have been placed on the list of approved fittings, and there has been a remarkable development and expansion in their field of usefulness. The company has many new designs, and has added materially to its stock of standard sizes.

THE AJAX LINE MATERIAL COMPANY, 12 South Jefferson street, Chicago, Ill., has furnished the following additional information concerning the controversy between it and the George Cutter Company, South Bend, Ind., in regard to the trade-mark "Ajax." The full text of the decision of the examiner of interferences is as follows: "An abandonment by the George Cutter Company of the trade-mark at issue in this interference having been filed, and the same having been found to comply with the requirements of Rule 125, it is adjudged that the Ajax Line Material Company, the junior party, is the owner of the trade-mark and entitled to the registration for which it has made application."

THE SOCIETE ANONYME H. CUENOD, of Geneva, Switzerland, has published a very handsome bulletin devoted to a description and illustrations of the automatic regulators designed on the system developed by R. Thury. The descriptive matter includes a discussion of the principles, advantages and applications of the apparatus. Special descriptive matter is devoted to the use of these regulators for isolated generators, for generators coupled in parallel, for generators used in three-phase distribution, for the regulation of feeder circuits, for the automatic control of accumulators, and for the regulation of apparatus placed at a distance from the controlling point. Copies of this catalogue, which is printed in French, will be furnished to those interested, upon application to the company.

THE GENERAL ELECTRIC COMPANY, Schenectady, N. Y., is distributing some attractive literature concerning several important types of apparatus. Bulletin No. 4,607 is devoted to the series incandescent system with tungsten lamps. This is a timely publication in view of the present general tendency toward the illumination of streets of residential districts by means of the series incandescent system of lighting. The descriptive matter in this bulletin includes illustrations and general data on transformers, switchboards, lamp brackets and reflectors, series sockets and lightning arresters used in connection with the system. Bulletin No. 4,608 describes the company's improved type H subway transformers. These transformers are absolutely water-tight, and are proportioned for the limited space in manholes, possess high efficiency and large radiating surfaces, and their temperature rise is small. The transformers are manufactured for a frequency of sixty cycles at standard voltages, and in capacities from five to 300 kilowatts, inclusive. Bulletin No. 4,610 describes a new line of small plant continuous-current switchboards equipped with the latest and most improved controlling devices. These boards are manufactured for 125 and 250-volt circuits only, and each panel forms a separate and complete switchboard not intended for combination with other panels. They are made to control one generator and two feeder circuits, and additional feeder switches can not be furnished. The panels are made of natural black slate, and are supported by one-inch gas-pipe supports. Folder No. 3,681 is devoted to a description of mercury arc rectifiers for moving-picture machines. This apparatus will operate satisfactorily on any alternating-current voltage from 200 to 240, and any frequency between forty and 140 cycles. Copies of this literature will be furnished to those interested upon request.

NEW INCORPORATIONS.

ST. PAUL, MINN.—Royalton Power and Light Company, of Royalton. $10,000. Incorporators: A. C. Wilson, Mark Murphy and Charles R. Rhoda.

JERSEY CITY, N. J.—Southwestern Development and Construction Company, Jersey City. To operate steam or electric railroads, etc. $100,000. Incorporators: H. B. Ferber, Hackensack; W. H. Nash, Jersey City; G. E. Waesche and W. H. Wieboldt, East Orange.

DOVER, DEL.—Central Texas Traction Company. To operate rapid transit railways for carrying freight, merchandise and passengers, and to operate mines and mine tramways. Incorporators: J. J. Sears, of Chicago; Dr. J. O. Howard, of Houston, Tex.; W. W. Clopton, of Corsicana, Tex.; J. V. Watkins, of Corsicana, and Harry W. Davis, of Wilmington. $300,000.

OLYMPIA, WASH.—Nooksack Valley Traction Company, of Bellingham. $1,250,000. Incorporators: W. R. Alward, J. S. Wheeler, J. E. Morrison, Edward Brown, W. H. Jarrett and J. William Welch. To build a line of railway from a point at or near Bellingham to a point in or near the city of Blaine, and from said point at or near said Bellingham to a point at or near Sumas.

INDIANAPOLIS, IND.—Marion & Logansport Traction Company. $40,000. To build a traction line in and through the following towns: Marion, Sweetser and Nier, in Grant County; Converse, Amboy, North Grove, McGrawsville and Bunker Hill, in Miami County, and Logansport, Anoka and Onward, in Cass County. Incorporators: George D. Lindsay, Marion; John O. Spurgeon, Sweetser; Mead S. Hays, Marion; John Minnick, Grant County, R. R. No. 10; John O. Wilson, Marion; Lewis S. Marks, Marion; Alva Williamson, Sweetser, and Carl Wise and Victor Wise, Logansport.

Record of Electrical Patents.

Week of August 11.

895,421. MAIL-POUCH RECEIVING APPARATUS FOR RAILWAY CARS. Chauncey W. Broughton, Carlton, Ill. A magnetically controlled mail-pouch delivering apparatus.

895,422. MAIL-POUCH RECEIVING OR DELIVERING APPARATUS FOR RAILWAY CARS. Chauncey W. Broughton, Carlton, Ill. An electromagnet is in combination with a support for sustaining a mail pouch adjacent to a railway track.

895,431. ENCLOSED FUSE. Robert C. Cole, Hartford, Ct., assignor to the Johns-Pratt Company, Hartford, Ct. The fuse receptacle is filled with comminuted material which is retained by lint or fuzzy material without impeding the escape of gases.

895,432. ENCLOSED-FUSE TERMINAL. Robert C. Cole, Hartford Ct., assignor to the Johns-Pratt Company, Hartford, Ct. A tubular casing containing a fuse link with link terminals.

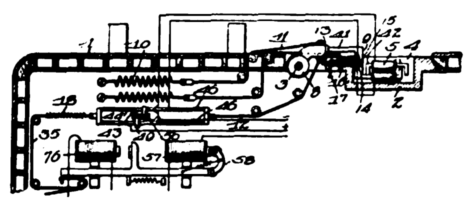
895,434. VEHICLE-SPEED SIGNAL. George L. Cooper, Troy, N. Y., assignor of thirty-five one-hundredths to Joseph F. Bush, Schenectady, N. Y. The starting movement actuates a visual signal on the car.

895,441. ELECTRIC OUTLET BOX. Conrad J. Dorff, Chicago, Ill., assignor to Frederic Greer, Chicago, Ill. The outlet box is provided with self-retaining knockouts.

895,443. COIN-BOX FOR TELEPHONES. Charles S. Ellis, Chicago, Ill., assignor to the American Coin Register Company. The coin-box is provided with sectional coin channels.

895,460. THERMOSTATIC CIRCUIT-CONTROLLER. Herman L. Hicks, Martins Ferry, Ohio, The electric circuit is closed by the alternate heating and cooling of the expansion member.

895,485. VACUUM-TUBE LIGHTING. Daniel M. Moore, Newark, N. J., assignor to Moore Electrical Company, New York, N. Y. The tubes extend to several floors from a common centre of distribution.



895,421.—MAIL-POUCH RECEIVING APPARATUS FOR RAILWAY CARS.

895,486. VACUUM-TUBE APPARATUS. Daniel M. Moore, Newark, N. J., assignor to Moore Electrical Company, New York, N. Y. The rarefied gas is admitted to the tubes through a valve automatically in response to changes of gas tension in the tube.

895,487. VACUUM-TUBE APPARATUS. Daniel M. Moore, Newark, N. J., assignor to Moore Electrical Company, New York, N. Y. The system is equipped with a device regulating the flow of gas or vapor to maintain a constant tension in the vacuum tube.

895,490. SYSTEM FOR THE GENERATION AND DISTRIBUTION OF ELECTRICITY. Thomas H. McAdory, Chicago, Ill., assignor to the Adams & Westlake Company. The resistance of the distribution system is controlled by an automatic regulator depending upon the voltage of the battery.

895,515. DYNAMOELECTRIC MACHINE. Egbert M. Tingley, Pittsburg, Pa., assignor to Westinghouse Electric and Manufacturing Company. The machine has a cylindrical core member provided with longitudinal ventilating slots.

895,531. SILOXICON-COATED CARBON-CONTAINING ARTICLE. Edward G. Acheson, Niagara Falls, N. Y. The carbon-containing article has its outer portion covered with siloxicon.

895,545. CONNECTING DEVICE FOR ELECTRICAL CONDUCTORS. Ernest B. Fahnestock, New York, N. Y. A self-contained spring member forms a connecting clamp in combination with a hook and conductor.

895,549. STORAGE BATTERY. George A. Ford, Cleveland, Ohio, assignor to Harriet S. Ford, Cleveland, Ohio. The battery is formed of trays molded from paper pulp.

895,575. ELECTRIC CAR-RECORDING BLOCK-SIGNAL. William J. Murray, Leavenworth, Kan., assignor of one-half to Herbert W. Wolcott, Leavenworth, Kan. The block-signal system is equipped with a step-by-step recording device.

895,582. RAIL-BOND FOR ELECTRIC RAILWAYS. William E. Oakley, Millbury, Mass., assignor to Worcester Steel Foundry Company, Worcester, Mass. The terminal is welded to the connector and is composed of an alloy having the same temperature coefficient as that of the rail.

895,589. ELECTRIC SIGNAL FOR RAILWAYS. John S. Sims, Longbeach, Cal., assignor of one-half to Edward Richard Millar, Longbeach, Cal. The signal targets are held in inoperative position by the normally charged magnets.

895,594. ARC LAMP. Bernard A. Stowe, Cleveland, Ohio, assignor to the Jandus Electric Company, Cleveland, Ohio. The arc chamber is provided with a tube for carrying off the gases.

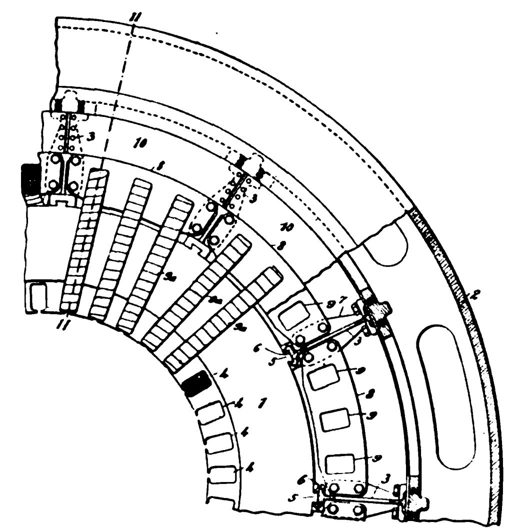
895,618. POWER-TRANSMITTING DEVICE. Leonard K. Clark, New York, N. Y. A flexible mechanical coupling.

895,660. ELECTRIC BATTERY. William Morrison, Chicago, Ill., assignor to George Rumrill Coryell, Chicago, Ill. A bromin-carbon primary cell.

895,714. BINDING-POST. Garrison Babcock and Josef Reuter, Rochester, N. Y., assignor to Merton E. Lewis, Rochester, N. Y. The terminal is formed of a base, a member with an inclined clamping face, and a locknut.

895,715. THERMOCHEMICAL GENERATION OF ELECTRICITY. Lucien P. Basset, Paris, France, assignor to Maurice Bacqua de Labarthe, Paris, France. Two electrolytes are circulated in separate compartments divided by porous walls.

895,729. ART OF SEPARATING SUSPENDED PARTICLES FROM GASEOUS BODIES. Frederick G. Cottrell, Berkeley, Cal., assignor to International Precipitation Company, San Francisco, Cal. The gaseous bodies are subjected to the action of a system of electrodes maintained at a high difference of electrical potential.



895,515.—DYNAMOELECTRIC MACHINE.

895,732. CONSTRUCTION OF BATTERIES AND ELECTROLYTIC APPARATUS. Frank A. Decker, Philadelphia, Pa., assignor, by mesne assignments, to Decker Electrical Manufacturing Company, Wilmington, Del. The battery parts are enclosed in a rubber diaphragm sealed by a plastic vulcanized material.

895,738. SOLID INSULATING COMPOUND. Jerome W. Frank, New York, N. Y., assignor to Standard Varnish Works, New York, N. Y. A solid insulating compound composed of oils and gums.

895,747. BINDING-POST. Monroe Guett, Hartford, Ct., assignor to the Hart & Hegeman Manufacturing Company, Hartford, Ct. A cylindrical binding-post with a central bore and two openings in the side wall through which operate non-rotatable studs.

895,752. LIGHTNING ARRESTER. Ernst Heddaeus and Rudolf Nothnagel, Bilbao, Spain. One of the two rotating discharge bodies has a plurality of cam surfaces, varying the distances of the surfaces of the rotating members.

895,760. SYSTEM OF ELECTRICAL DISTRIBUTION. Robert C. Hull, Philadelphia, Pa. A regulating apparatus causes the battery to charge and discharge in response to the electrical condition of the circuit.

895,772. SECONDARY ELECTRIC CLOCK. Frank F. Landis, Waynesboro, Pa. The apparatus is operated by a step-by-step electromagnetic device.

895,777. COIN-OPERATED ATTACHMENT FOR PAY-TELEPHONES. Edmond J. Lonergan, Chicago, Ill. The coin is deposited through a reciprocable coin chute.

895,785. MEANS FOR SUPPLYING AND CONTROLLING ELECTRIC CURRENT TO MOTOR VEHICLES. Alexander Palmbos, Columbus, Ohio, assignor to the Jeffrey Manufacturing Company, Columbus, Ohio. A storage battery car equipped with a trolley support.

895,801. CURRENT TRANSFORMER. Paul Schubert, Berlin, Germany, assignor to General Electric Company. The transformer is provided with means for producing two opposing alternating fluxes in the core.

895,806. TROLLEY. Frank L. Sessions, Columbus, Ohio, assignor, by mesne assignments, to the Jeffrey Manufacturing Company. The trolley pole has both a lateral and longitudinal movement.

895,822. RHEOSTAT. Charles Wirt, Philadelphia, Pa., assignor to Charles Wirt & Company, Newark, N. J. The resistance, conductor, contact blocks and hub are contained in a molded body of insulation.

895,823. SYSTEM OF ELECTRICAL DISTRIBUTION. Joseph L. Woodbridge, Philadelphia, Pa. A combination of a polyphase and a single-phase alternating-current circuit connected, respectively, to a synchronous dynamoelectric machine and an induction machine.

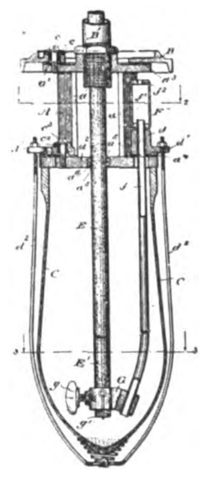
895,824. ELECTRIC GENERATOR. Joseph L. Woodbridge, Philadelphia, Pa. The pole frame is provided with polar projections in groups of three.

895,825. SYSTEM OF ELECTRICAL DISTRIBUTION. Joseph L. Woodbridge, Philadelphia, Pa. The regulating apparatus is responsive to rapid fluctuations in load.

895,830. ELECTRIC BRAKE. Edward H. Anderson, Schenectady, N. Y., assignor to General Electric Company. The hand brake is supplemented by a motor-driven device.

895,831. CONSTANT-CURRENT TRANSFORMER. Lyman Arnold, Lynn, Mass., assignor to General Electric Company. The transformer is provided with a plurality of axially aligned sets of relatively movable primary and secondary coils with a magnetic core.

895,836. CONTROLLING DEVICE FOR ELECTRIC MOTORS. Ralph E. Barker, Lynn, Mass., assignor to General Electric Company. There is a winding operating independently of the automatically changing windings.



895,594.—ARC LAMP.

895,848. ELEVATOR SAFETY AND ANNOUNCING DEVICE. George H. Foulks, San Francisco, Cal. Devices carried by the doors act automatically when brought into the range of action of the brake or stop mechanism carried upon the cage.

895,857. RESISTANCE UNIT. Joseph L. R. Hayden, Schenectady, N. Y., assignor to General Electric Company. A cast silicon rod terminates in iron terminals.

895,864. TROLLEY. Albert S. Janin, New York, N. Y., assignor of one-third to Amelia Janin, Brooklyn, N. Y. A pantograph collector with spring-actuated members.

895,869. RECTIFIER SYSTEM. Osias O. Kruh, Schenectady, N. Y., assignor to General Electric Company. The secondaries of the single-phase, alternating-current source are connected in multiple.

895,870. PROPELLED TORPEDO. Howard Lacy, Carshalton, England. The torpedo head is equipped with a magnet and magnet core.

895,878. BRUSH-HOLDER. Floyd C. Mitchell, Schenectady, N. Y., assignor to General Electric Company. The brush stud is equipped with a resilient member.

895,887. ACYCLIC MACHINE. Jakob E. Noeggerath, Schenectady, N. Y., assignor to General Electric Company. The acyclic poles extend uniformly around the armature.

895,888. UNIPOLAR DYNAMOELECTRIC MACHINE. Jakob E. Noeggerath, Schenectady, N. Y., assignor to General Electric Company. A unipolar field structure, and an armature provided with a plurality of collector rings.

895,894. MEANS FOR COOLING DYNAMOELECTRIC MACHINES. Richard H. Rice, Lynn, Mass., assignor to General Electric Company. An inner and outer ventilating case for vertical turbines.

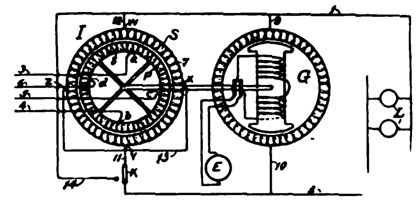
895,911. WALL BRACKET FOR ELECTRICAL CONDUCTORS. Lucius Tinsley, Crawfordsville, Ind. A wall bracket with a plurality of insulating members and a clamping member attached to the base.

895,914. VARIABLE-VOLTAGE TRANSFORMER. Matthew O. Troy, Schenectady, N. Y., assignor to General Electric Company. The core is adapted to afford two magnetic circuits, one passing through both coils, and one shunting one coil.

895,916. LIGHTNING-ROD TERMINAL. John P. Turner, New York, N. Y. A tapered, perforated body of sheet metal filled with carbon forms a self-contained ground plate.

895,925. ELECTRIC ORGAN. William R. Whitehorne, Bethlehem, Pa. The valves and stops are controlled by electromagnets.

895,928. RAIL-BOND. Montraville M. Wood, Chicago, Ill., assignor to General Electric Company. The bond head has a receptacle accommodating a piercing pin.



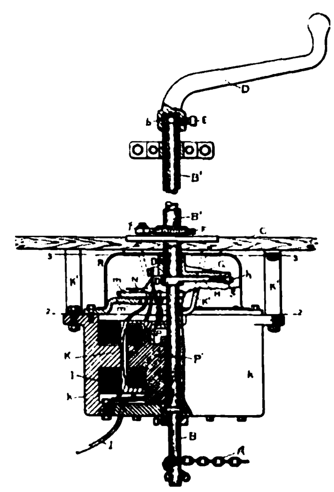
895,823.—SYSTEM OF ELECTRICAL DISTRIBUTION.

895,930. PROCESS OF ELECTROLYTICALLY PRODUCING CHROMIC ACID FROM CHROMIC SULPHATE. Gustav Adolph, Ammendorf, and Albert Pietzsch, Magdeburg, Germany, assignors to Chemische Fabrik Buckau, Magdeburg, Germany. The reducing action of the nascent hydrogen is minimized by electrolyzing the chromic solutions in the absence of a diaphragm.

895,933. SELF-EXCITING GENERATOR. Ernst F. W. Alexanderson and Emil H. Widegren, Schnectady, N. Y. The field winding is provided with a rectifying commutator and a polyphase arrangement of brushes.

895,956. LIGHTNING-ARRESTER RESISTANCE. Harold W. Buck, New York, N. Y., assignor to General Electric Company. The flexible heat-proof envelope contains granular resistance material.

895,958. ELECTROMAGNETIC SPARKING PLUG. Otto Carlborg, Providence, R. I. The sparking plug is equipped with an electromagnetic interrupting member.



895,830.—ELECTRIC BRAKE.

895,965. REGULATION OF DYNAMOELECTRIC MACHINES. Reginald C. Clinker, Rugby, England. Means are provided for varying the effect of a shunt in proportion to the rate of change of load in circuit.

895,993. TROLLEY SUPPORT. Hiram G. Farr, Melrose Highlands, Mass. The trolley wheel is chambered and provided with a core of absorbent packing.

896,060. FILAMENT FOR ELECTRIC INCANDESCENT LAMPS AND PROCESS OF MAKING THE SAME. Hans Kuzel, Baden, near Vienna, Austria-Hungary. The filaments are produced from a plastic mass containing tungsten and colloidal oxynitrid of tungsten, forming threads capable of being converted into a crystalline tungsten filament.

896,071. ELECTRIC RAILWAY. John A. Garey, Mound City, Mo., assignor of one-half to George G. Garey, Indianapolis, Ind. A third rail and means for supporting same in a conduit of spring-closed sections.

ELECTRICAL REVIEW

THE PIONEER ELECTRICAL WEEKLY OF AMERICA

VOL. LIII. No. 9 NEW YORK, SATURDAY, AUGUST 29, 1908. ISSUED WEEKLY

Published weekly by the Electrical Review Publishing Company, 13 Park Row, New York. Charles W. Price, president and treasurer; Stephen H. Goddard, vice-president; H. S. Tuthill, secretary.

Entered at the Post Office at New York as second-class matter under the Act of March 3, 1879.

CONTENTS

THE SURFACE-CONTACT SYSTEM CONDEMNED IN LONDON.

Our London exchanges report the condemnation of the surface-contact system installed this year by the London County Council in place of a horse-car line on High street, Whitechapel. This at first seems to be a natural consequence. At least it has been the result of numerous other attempts to install similar systems. Indeed, so many attempts to develop a successful surface-contact system have been abandoned for one reason or another that it was a surprise when the London authorities decided to give such a system a trial. But if the accounts given of the method followed by the council in installing this system are accurate, it is evident that it was not given a fair trial, and engineering opinion should be held in abeyance until the tangle in London has been unraveled.

The system which was tried is known as the "G. B." system, and it has been in operation for nearly three years in Lincoln, England, apparently with success. We gather, from our exchanges, that the London County Council has reached a point where it must consider some other than the conduit system because of the enormous expense of installing the latter. It first considered the introduction of the overhead trolley system on this line, but met with severe opposition from the residents along the route, and it therefore decided to give the "G. B." system a trial, thinking that if this proved satisfactory all would be well; and, if it did not, the council could then proceed to install the overhead wires, since it could then say that the only other available system had been tried and had failed. It will be recalled that one reason given for the trial of the surface-contact system was the presence of an underground line along part of the route, and there was not room enough between the top of the tube and the surface of the ground for a conduit.

Be this as it may, from the accounts of the method which the council followed when installing the contact system, it seems clear that the responsibility for its failure rests entirely upon the council and not upon the system. The council's engineers refused to accept advice from the engineers who had had experience with the system, and altered the apparatus and installed parts condemned by the engineers of the company, although the latter had retained the power to condemn any part of the apparatus installed. After the council had notified the company of its intention to abandon the system the company offered to reconstruct it at its own expense and operate it for one year, at which time the council should decide whether it were successful or not, but this proposal was rejected. Evidently we have not heard the last of this matter, since the company can not afford to accept defeat so easily.

Aside from this particular dispute, the London County Council evidently has a troublesome question to answer. It can not go on forever constructing conduit lines, and the people of London apparently will not hear of the overhead trolley. Just how it will get out of this difficulty remains to be seen, but it will not help matters if, as one of our London contemporaries hints, it tries other systems with the expectation, if not the determination, that they shall fail.

THE GASOLENE-ELECTRIC DRIVE FOR VEHICLES.

A short time ago we discussed the proposed application of electrical transmission to ship propulsion and commented upon the paper read recently by Mr. W. P. Durtnall before the Institution of Marine Engineers in London. In spite of the losses necessitated by the double transformation involved in this system, Mr. Durtnall apparently made out a very good case for the electric motor. If his figures be accepted the electric system will save largely in weight of the propelling machinery due to the smaller boiler equipment required when the turbines and propellers may both be driven at their most efficient speed. When this is the case the increased economy of both turbines and propellers so reduces the demand for steam that the boiler equipment is considerably smaller than for the direct steam drive, and since by far the greater portion of the weight is in this part of the equipment, the total weight of machinery is reduced by more than 100 tons in the instance mentioned, and there is, in addition, a very appreciable saving in fuel.

Following shortly after this and, perhaps, inspired by Mr. Durtnall's paper, Mr. Frank Broadbent, in the *Electrical Review*, of London, for July 24, discusses the application of the electric drive for propelling vehicles. This system is now being tried in a number of instances, as are several other self-contained systems, so that a preliminary comparison at least may now be made, which is done here.

It is interesting to recall at this time the first attempt to utilize the electrical system of transmission for propelling a self-contained vehicle. This was the Heilmann locomotive, constructed in 1892 or thereabouts. Heilmann's idea is not entirely clear, since he installed a complete power-house on his locomotive and then attempted to use it in competition with steam locomotives for express service. He had a steam boiler and steam engine driving a generator which charged a storage battery on the locomotive and drove the motors, which were geared to the locomotive axles. At that time he did not have the prime mover which to-day seems to promise best for such service, that is to say, an internal combustion engine. Just how large this equipment was we do not now recall, but it probably was considerably too small for the use to which he put it. Moreover, one of the great advantages of such a system, if, indeed, it be not the most important advantage of all, is the rapid acceleration made possible by such an equipment. Yet this characteristic was of little value for the service to which he put his locomotive; that is to say, for high-speed runs with few stops. The locomotive, if we remember correctly, never advanced beyond an early experimental stage, and the few trials made of it showed it was inadequate for the service for which it was intended. Heilmann, however, deserves the credit for the first attempt to interpose the electric generator and motor between the prime mover of a vehicle and its axles.

Within the last year or two this system has again been taken up and tried not only for railway service, but for road vehicles as well. In the article by Mr. Broadbent, referred to above, the advantages of this system for local traffic on railways are considered and the system itself is compared with other new systems proposed and being tried for such service. He has obtained some figures showing the cost of operation of a number of these systems on the Hungarian railways, where they are being tried out with the view of determining whether any one of them will prove satisfactory for handling the traffic on these roads. As is to be expected, the electric system, involving as it does a double transformation, shows a slightly higher fuel cost than do some of the more direct systems, but the reliability and the doing away with heavy gearing, as well as protecting the prime mover from shocks, so reduce the cost of maintenance that the total cost for operation is less for the electric system than for the others. For example, it has been found that a steam equipment showed a total cost of operation of six and one-quarter cents a car-kilometre, while a gasolene-electric equipment costs only 5.75; moreover the cost for this steam car is the average of over a million and a half kilometres of running, while that of the gasolene-electric cars is for a service of less than one-tenth this. It seems likely that the average for the electric system will be reduced upon longer trial.

These figures, as well as others given by Mr. Broadbent, show the advantage of the gasolene-electric system, although it would not have been surprising if there had been less difference between the two, or even if the total cost of operation for the steam car had been found to be little less than that of the other. It is in other ways that the electric system gains most. The system of control is simple, and makes it possible for the driver to run at almost any speed necessary, and to do so efficiently; and it is hardly necessary to add that for short hauls and many stops the rapid acceleration given by the electric motor is a very great advantage, for on this depends largely the schedule which can be given on any such line.

Mr. Broadbent points out also the advantages of the mixed system for road vehicles. A self-propelled car equipped in this way has all the advantages of the electric automobile and is limited in its distance of run only by the fuel which it can carry. For city traffic the perfect control which the driver has over his car is most valuable. He can reduce the speed to a mere crawl without reducing the torque developed by his motors. He can start quickly and thus work his way along the street much more effectively than can be done with other systems; and, here again, the substitution of the electric transmission for gearing eliminates an expensive and weak part of the car equipment.

Mr. Broadbent believes that some such system will demonstrate its superiority for city service, and replace, to a large extent, the more direct but less satisfactory systems now in use.

It is perhaps proper to state here that this system was tried some years ago and was found to operate well. In fact, an automobile equipped with a gasolene-electric drive was entered in the New York-Boston endurance race, which took place in October, 1902. It is much to be regretted that for several reasons this car did not make a very good showing, although no fault whatever could be found with the electrical part of the equipment. The owner of the car had ordered a new engine and did not receive it until the day before the race, and when installing it hurriedly a nut fell into the cooling water system which smashed the impeller of the circulating pump, so that the engine got hot and refused to run after about an hour's service. This fault was not located until too late. But until the engine became overheated the car ran without a hitch.

Mr. Broadbent's stand is well taken; and, if it be borne in mind that the gasolene-electric system has been tried for a short time only, and not all of the weaker points have been perhaps sufficiently strengthened, the possibilities of the system may be imagined. Those who remember the hard and disheartening struggle to introduce the electric street car will not be discouraged by the first few failures. It is true that we know much more about the propulsion of vehicles to-day than we did twenty years ago, but we still have much to learn, particularly in the field of self-propelling road vehicles and in the use of self-contained cars for light railway service.

DIRECTIVE WIRELESS TELEGRAPHY.

From time to time we have noticed various attempts to control the direction of propagation of electric waves employed in wireless telegraphy. One or two of these are reported to have shown satisfactory results during experiments and have even been employed in actual service. On another page of this issue a new system is described due to Dr. F. Kiebitz, who has patented his system in Germany and has obtained experimental results which, although resulting from trials on a rather small scale, are encouraging. The method in brief consists in setting up an oscillating magnetic field at an angle of about sixty degrees to an oscillating electric field. The result is the production of electric waves having a maximum amplitude in the direction normal to the two directions of oscillation.

Such a system, of course, radiates in all directions, but it is stated that the intensity of radiation in the maximum direction was seventy times that in the minimum direction, and at an angle of forty-five degrees to the maximum direction the energy of radiation was only one-third of that in the maximum direction.

The value of controlling the direction of radiation of wireless signals is great, but it is well to remember that this control can be secured through fairly wide angles only. In the present instance it is probable that all apparatus which would operate satisfactorily in the direction of maximum transmission would also be affected within thirty degrees on either side of this direction, and hence not more than two such systems could be operated successfully if tuned to the same pitch in the same territory. The system, of course, radiates symmetrically about one axis, sending out equal maximum radiations in opposite directions. And another point which must not be overlooked is the variability of wireless signals during the day, so that the only way to be sure that the signal will reach the receiving instrument is to be sure that it is strong enough. Obviously such a system of operation is not conducive to directive control of transmission.

CONCRETE POLES FOR ELECTRICAL TRANSMISSION.

The increasing price of timber for all constructional purposes presents a serious problem to the engineer. Hence any method of preventing decay which will reduce the total cost of the lumber is acceptable. But the problem is being attacked in further directions, and many engineers are seeking substitutes for wood. One of the most promising materials for this purpose is concrete reinforced by steel. With this material the use of wood may be frequently avoided, and, indeed, with a proper method of construction the reinforced concrete may be made to take the place of wood in cases where it might at first seem to stand no chance. For example, reinforced concrete poles are now being used with reported success not only from the constructional standpoint, but from that of the cost as well. Elsewhere in this issue is described a method of constructing hollow poles of reinforced concrete, which has been employed in Germany. Not only is the pole thus formed a very satisfactory device for supporting an electric line, but it is estimated that such a pole would have a life of fifty years without, in that time, having cost anything for maintenance. On such a basis the cost for the pole during that time would be less than half what it would cost to maintain either an iron or a wooden pole in the same position.

DECREASE IN STEAM AND ELECTRIC RAILROAD EARNINGS COMPARED.

A comparison of the earnings of six important street railways and an equal number of steam railroads for a three months' period during the last six or eight months brings to light several interesting facts. Gross earnings of the six street railways during the period aggregated $14,012,170, against $14,025,477 in the same months of the previous year, a decrease of $13,307, or less than one-half of one per cent. Gross receipts of the six steam roads, on the other hand, for the three months' period aggregated but $79,840,909, against $95,473,826 in the same months of 1907, a loss of $15,623,827, or over nineteen per cent.

The explanation of this is to be found in the different character of traffic of electric and steam roads. Ninety-five per cent of the gross earnings of electric railways is derived from passenger receipts, while from sixty-five to seventy per cent of the steam railroad gross is realized from freight. In periods of universal curtailment, therefore, the freight earnings are one of the first to indicate such substantial depression.

Convention of the Michigan Electric Association.

The annual convention of the Michigan Electric Association was held at Grand Rapids, Mich., August 18, 19 and 20. Headquarters were established at the Hotel Pantlind. The meeting was called to order by President H. W. Hillman on the morning of August 18.

The chairman of the Board of Public Works, Mr. Prestley, on behalf of the mayor, welcomed the members to the city.

The presidential address recommended a change in the constitution to permit the election of associate members and also outlined a plan for increasing the membership.

The first topical discussion was entitled "Various Experiences with Tungsten Lamps." E. F. Phillips, of the Detroit Edison Company, related that company's experience in lighting the suburban village of Grosse Point with tungsten lamps, supplying current through an underground system 11,500 feet long. Forty-two ornamental iron poles with brackets and with two lamps on each pole were erected. The contract called for at least fifty-candle-power lamps. The company installed, last November, sixty-candle-power, seventy-five-watt series tungsten lamps, each lamp taking five and one-half amperes. These were alternating-current lamps. The renewals for burned-out lamps threatened to become a burden. The company finally dropped the current consumption to five amperes, and obtained very satisfactory results. The service is eminently pleasing to the customers, and the company is satisfied with the system as it is now operated.

F. T. Masterson, of Grand Rapids, described the series tungsten-lamp system on Canal street, in Grand Rapids. This installation consists of fifteen spans across the street, with eighteen sixty-candle-power, seventy-five-watt lamps in series on each span. The spans are spaced 100 feet apart. All of the material, except the lamps, is owned by the Canal Street Merchants' Association. The lamps and current are furnished by the Grand Rapids-Muskegon Power Company. The initial expense of installation for material and labor was about $50 a span, or $750 in all, divided among so many merchants that the individual expense was small. The power company, representing itself as one of the merchants because of a small retail store, stood its *pro rata* share of the expense. The Grand Rapids Electrical Company, a supply dealer, secured the contract for erection and furnishing the material. The installation is permanent.

The proposition appears to be very attractive from the standpoint of the merchants and is considered a forcible advertisement for their businesses. Since the installation was made the crowds of people who flock to that street offer ample evidence of its success from an advertising point of view. The expense for operation is divided among so many merchants that some of them do not pay more than $1 a month. The power company made a special feature of billing separately to the merchants, thus making the least trouble to the association. In view of dealing with a merchants' association, it appeared necessary for the company to make a contract price based on renewal and maintenance of lamps. The power company would not care to take additional business of a similar character at less than $7 per lamp per year.

William Chandler, of the Sault Ste. Marie Electric and Power Company, related the experiences of his company in a paper prepared by himself and D. B. South. The company has noted no bad effect upon the lamp from voltage fluctuations, although its regulation is quite good. The company was one of the first to make any considerable installation of tungsten lamps in a commercial way. Notwithstanding some drawbacks incident to some manufacturing defects in the early type of lamp, there seems to be no reason to doubt the wisdom of the company's decision that the thirty-volt series type of lamp is the best to use. A special fixture burning four forty or fifty-candle-power lamps in a cluster was also decided upon. The company's first order was for lamps taking from fifty-five to fifty-seven watts per lamp and giving about forty candle-power. While these gave a fine illumination, they could not be made to compete in cost with the gas arc, as the company desired, under its operating conditions. The company has had better satisfaction with the forty-candle-power lamps, and some of these have been burning 1,400 hours, with little if any diminution of light.

The company adopted the plan of either selling the lamp outright at $1.50, or renting a set of four at fifty cents per month and maintaining the lamps. This places them on the same basis as gas arcs in the city, or less, as far as the cost of service is concerned, but in quality the illumination from gas can not be compared with the tungsten lamps.

The company has made no attempt to secure residential lighting with tungsten lamps, and does not believe that the series method of installation would meet with much favor in such lighting.

The paper also described a number of installations where the tungsten lamp had satisfactorily displaced installations of gas arcs.

H. A. Chase, of the Hart Electric Light and Waterworks, Hart, Mich., read a paper entitled "Street Lighting by Tungsten Lamps." The city of Hart is thickly lined with shade trees, making it almost impossible to illuminate the streets with arcs and procure an even distribution of light. It was decided to try lighting the main street with tungsten lamps. This trial of twenty lamps gave such excellent satisfaction that the company has now sixty-two tungsten lamps installed, and expects within a year to have the village lighted throughout with the same type of lamp. Sixty-candle-power, seventy-five-watt series tungsten lamps were used, placed three to the block alternately across the street. This spaces the lamps about 150 to 200 feet apart. The lamps are placed about twelve feet from the ground, giving a fine distribution of light. On one street, where there are no trees for about half a mile, lamps have been placed on every other pole, spacing them about 300 feet apart. This gives almost as much satisfaction as the shaded streets with the lights nearer together. Through the business part of the town series alternating-current arc lamps were used on the same circuit with the tungsten lamps.

The first twenty lamps have burned 464 hours with only three burnouts. The first lamp that burned out had burned for ninety-two hours; the second, 182 hours, and the third, 184 hours. The last forty-two lamps installed have burned 180 hours with two burnouts. The first burned out after twenty-five hours and the second after 140 hours.

Mr. Chase believes that the cost of installation is a little more than with arc lamps, but when the difference in the distribution of light is compared, the extra cost is not to be considered. The cost of installing sixty-two tungsten lamps and four arc lamps, including reconstruction of the old lines and one Fort Wayne twenty-five-light arc regulator switchboard and transformer, and three-quarters of a mile of new line, was $2,252. While there was quite a little breakage in the first shipment of lamps, the supply company made up this breakage in full. The campany has one lamp which has fallen twice to the ground, a distance of twelve feet, and is still burning. This is a rather remarkable evidence of the present strength of the lamp and an indication of the future perfection that may be attained.

A. C. Marshall, general superintendent of the Port Huron Electric Light and Power Company, stated that shortly after the multiple tungsten lamps came on the market it became evident that there was a considerable demand for the new form of lamp. The company laid in a stock of sixty and 100-watt lamps and sold them at list price. The company also sold Holophane reflectors with each lamp, and recently the company's customers are making quite a demand for the tungsten lamp, as a considerable reduction is found in the cost of lighting. Mr. Marshall thinks that from the present outlook it is going to be hard after a while to get enough new business to keep offsetting the reduction in the old customers' bills. The merchants are now lighting their whole stores for what it previously cost them to light the windows only. He does not think it practicable to recommend tungsten lamps for residence lighting.

Alex Dow, vice-president and general manager of the Edison Illuminating Company, of Detroit, suggested that anything that would reduce the cost of wiring the ordinary small residence should be looked into very carefully. The small householder is afraid of the cost of electric lights. At the same time the company can not afford to stand the expense of making such an installation purely for the return which may be made by the purchase of current.

W. J. Trott, Michigan manager of the Fostoria Incandescent Lamp Company, described the recent improvements in tungsten lamps.

Darwin D. Cody, of the Grand Rapids Electric Company, related some experiences with the tungsten lamp, his opinion being entirely favorable.

F. T. Benson, manager of the tungsten lamp department of the Chicago office of the General Electric Company, said that perhaps the new 250-watt tungsten will in many cases take the place of the arc lamp for street lighting. Experiments were being conducted with a view of strengthening the filament, perhaps by alloying the tungsten with other metals. No definite statement concerning this matter could be made at this time.

George D. Westover, manager and chief engineer of the Cadillac Water and Light Company, said he believed in going after the small-residence lighting consumer. He has 300 customers on his books who do not earn wages exceeding $2 a day. These workmen are able to afford electric lights in their homes. He uses one transformer in the centre of a block of houses. A meter is installed for each customer and the company gets from $9 to $15 from each user of this class per year.

The meeting was adjourned until Wednesday morning after a brief executive session.

On Tuesday evening Dr. C. P. Steinmetz delivered an interesting lecture on "Lightning Phenomena." The lecture was illustrated with lantern slides and was enjoyed by a large number of guests in addition to the official attendants at the convention.

At the Wednesday morning session Dr. Steinmetz reviewed the development of electrical transmission systems during the past twenty-five years and made frequent references to the 100,000-volt line of the Grand Rapids-Muskegon Power Company.

C. L. Crosby read a paper entitled "Campaigning for Power."

Mr. Crosby holds that the first and most essential movement in dealing with the prospective customer is educational. The successful solicitor should understand steam engines, as in this way he is able to determine the actual effective power required, as well as the friction loss which might be excluded by the use of motors. By this means he may arrive at a very close estimate of the cost of operation by electricity. It is necessary also that he be familiar with the operation and efficiencies of gas engines under different load conditions. In competing with gas engines, the solicitor will find that his prospective customer very seldom figures any cost other than the gas bills sent him each month, and here it is necessary that the electrical solicitor demonstrate in as impressive a way as possible the cost for lubrication, cooling water, repairs, attendance, etc. The solicitor should be able to furnish to the customer figures not only on the cost of service, but also on the cost of motors, wiring, etc. He should be able to lay out the most satisfactory method of driving the shop, at the same time avoiding the installation of more power than is necessary. He should know the type of motor best suited for various types of machinery. The office should co-operate with the field force in handling customers, practising courtesy and attention with all inquirers.

A. C. Harris read a paper entitled "Electric Power Installation in a Wood-Working Plant." This paper described particularly the electrical devices used by the Grand Rapids Hand Screw Company.

Guy Lewis, manager of the Lewis Electric Company, of Grand Rapids, read a paper entitled "Ideal Relations Between the Central Stations and the Contractor."

Mr. Lewis is of the opinion that the central station should do no construction work except on very small jobs where it comes into close competition with the gas company. Central station solicitors should obtain house-wiring and other contracts and turn the work over to one of the local contractors. In return for this consideration the contractor should establish a schedule of prices for wiring houses and other small buildings that will be equitable to all concerned. This schedule should be used by the central station solicitors in going after all work. The contractor should use his influence in every way to create satisfied customers for the central station. It will be possible for him to allay much criticism that is unjustly directed at the central station. The central station should show consideration for the contractor and supply dealer in giving the latter a list of prospective motor and apparatus customers, so that all might be a solicitor for the man who wants to distribute current. The central station should place itself in a position not to do anything to reduce the contractor's profit, or in any way belittle him. The contractor therefore would have greater consideration for the central station, would exercise more care in the installation of apparatus, and reduce dissatisfaction and irritation.

In the afternoon the ladies visited the Air Dome, and the gentlemen inspected the high-voltage transmission system of the Grand Rapids-Muskegon Power Company. Visits were also made to the Grand Rapids Plaster Company's plant, and to the plant of the Fox Typewriter Company.

The closing session was held on Thursday morning. A paper was read by A. J. Mott, entitled "Electric Heating Devices."

Mr. Mott related the experience of a company in an eastern city where there was a good lighting load and a moderate day load of small motors. In its effort to increase the day load the company arranged for a kilowatt-hour rate of five cents to all persons who wired up separately for a complete kitchen outfit or luminous radiator, installing a separate meter, with a minimum rate of $1 per month. A demonstration was started in a large department store, this demonstration being advertised in the daily papers with full-page announcements. The direct results of this demonstration were not satisfactory, although it later proved to have been a very good advertisement. It was decided to start a house-to-house campaign, and a wagon and three boys were sent out, leaving a flat-iron in every other house or apartment. The wagon put out about twenty-five irons a day, and at the end of three weeks the company began to take them in again. On some days the company would collect twenty irons, and on other days none at all would come back. The average showed that over twenty irons out of each twenty-five were retained. Efforts were also made to install sewing-machine motors, percolators, water heaters and chafing dishes, and at the end of the summer campaign the company had out about 800 electric flat-irons, nine complete cooking outfits, twenty percolators, thirteen luminous radiators, thirty sewing-machine motors and thirty-five chafing dishes, besides a considerable number of water heaters and cigar lighters. The income amounted to $6 per year for each flat-iron, $48 per year for each kitchen outfit, $12 per year for each luminous radiator and $1 a year for each percolator and sewing-machine motor. The smaller articles, such as chafing dishes, hot-water heaters and cigar lighters, do not bring much income directly to the central station, but are good advertisements for the larger articles, from which an income can be derived.

Charles O. Blackford read a paper entitled "Electric Display Windows for Effectively Advertising Electricity."

Mr. Blackford thinks that many people do not realize the great number and beauty of the latest art-glass fixtures. A display of beautiful fixtures and portables in the window of the central station company's office proves to people the great opportunity offered to them for decorative purposes. If an electric company is successful in having beautiful and attractive displays, other merchants and dealers will comment on them, and they, too, will use something electrical in window trimming. The benefit received from such displays can scarcely be overestimated, because nearly everybody can use electric power in some way. The advertising man and the window trimmer should work together. In electric window trimming it is almost imperative to have motion, because electricity is energy. Something moving in the window will attract more attention and receive more thought than anything beautiful and artistic.

Errett L. Callahan read a paper entitled "Popularizing the Use of Electricity."

This paper describes the way in which a good deal of profitable central station business can be secured by fitting up a proper equipment for demonstration purposes and carrying on a campaign to bring to the notice of prospective customers the advantages of electric service. The plans which have proved of value in a number of cases are outlined, and reports are given from a dozen cities throughout the country where very successful campaigns for increasing the use of electricity have been carried out.

A paper was also read by John G. Gromberg, entitled "Electricity and the Fireless Cooker."

The following officers were elected:

President, H. W. Hillman, Grand Rapids.

Vice-president, F. B. Spencer, Sheboygan.

Secretary-treasurer, A. C. Marshall, Port Huron.

A number of manufacturers of electrical devices made attractive displays, the Nernst Lamp Company making an exhibit of a full line of the new Westinghouse-Nernst units. The many new features of these lamps, especially the screw burners and the wafer heaters, made an exhibit of unusual interest to the electrical men present.

The Westinghouse Electric and Manufacturing Company occupied a tastefully arranged booth at the end of the main corridor at the Pantlind Hotel, adjoining the convention headquarters.

Report on Ventilation for the New York Subway.

Bion J. Arnold, consulting engineer for the Public Service Commission, has submitted to that body a report on cooling and ventilating the subway.

Mr. Arnold says the most available ways of reducing the temperature are: First, refrigeration; second, cooling by water; third, blocking the automatic louvres open, and providing additional openings; fourth, frequent air changes by train movement and by the use of a centre wall, dividing the north and south bound tracks.

The report describes the four methods, and discards the first and second as being impracticable, under the circumstances, and then makes the following recommendations:

Block the present louvres open during the day, and allow them to operate at night when the fans are being run. Construct as many protected openings as practicable between the subway and the street. At the Fourteenth street and Grand Central stations install large disc fans to draw air from the street through the kiosks, and force this air in large volumes down upon and among the persons waiting for trains upon the platforms. Construct a solid, continuous division wall between the down-town and up-town express tracks, extending from the north end of Ninety-sixth street station to and including Brooklyn Bridge station. For the purpose of demonstrating the feasibility of such a wall, it is suggested that the section extending south from the centre wall now at Thirty-third street station be constructed first far enough south to include the Fourteenth street station. At stations, the upper half of the wall to have vertically sliding counterweighted windows between columns. The cost of a four-inch terra-cotta brick wall between Ninety-sixth street and the Brooklyn Bridge should not be over $76,000, or $2.25 per running foot. The cost of a concrete wall in the same section should not be over $130,000, or $3.85 per running foot.

The commission will probably hold a conference with the Interborough representatives before acting upon Mr. Arnold's recommendations, as the building of a wall of the kind described would increase the bonded debt, and, therefore, the rental of the subway.

The Electrical Equipment of the Ferndale Collieries, South Wales.

The Ferndale Collieries are situated twenty miles north of Cardiff, Wales, in one of the Rhondda valleys. They include a series of pits dotted over some three miles along the bottom of the valley. Their yearly output amounts to nearly one and three-quarters millions tons and they employ about 6,500 men. In order to secure greater efficiency in the operation of the many power-consuming appliances, the steam drive has been abandoned recently for the electric drive. A modern generating station has been installed at Tylorstown, at the lower end of the series of pits, and power is distributed from it at 6,600 volts to transformer substations at the different pits. The power-house is a handsome steel and brick structure equipped with every modern appliance. It contains four water-tube boilers with superheaters, each capable of evaporating 30,000 pounds of water an hour at 150 pounds pressure and 150 degrees Fahrenheit superheat. Each has underfeed mechanical stokers and operates under forced draft. A complete coal-handling system has been installed to take the coal from the cars and deliver it to the bins, whence it is fed by gravity to the furnaces. The water supply is pumped from one of the pits. The engine-house equipment consists of three Sulzer cross-compound engines, each rated at 2,500 horsepower and coupled to three Lahmeyer three-phase flywheel-type alternators, running at ninety-four revolutions a minute. There are three cooling towers through which the water is circulated by pumps driven by sixty-horse-power induction motors of the slip-ring type. The cooling towers are thirty-three feet in diameter and eighty-three feet high. The main generators are rated at 1,600 kilowatts at eighty-five per cent power-factor. The overload rating is twenty per cent for two hours, or thirty per cent for half an hour. Excitation is furnished by a steam-driven set of seventy kilowatts rating and a motor-generator booster set rated at 120 kilowatts, which also charges the exciting battery. The battery can also be charged by the steam-driven set if necessary. The switch gear is arranged in three galleries at one end of the engine room. The operating gallery is the middle one and consists of a benchboard of three panels and a series of seven feeder pillars. The switch handles are of the loose type, mechanically coupled to the oil switches on the gallery below. The feeder pillars control three transmission lines, the station supply and the supplies to four of the pits. The distributing stations have, in general, three floors. The transformers are on the ground floor, the switches on the second and the lightning arresters on the third. The potential is lowered here from 6,600 to 2,200. At the pits it is again lowered to 440 for motors and surface lighting. Twenty-two hoisting gears are being installed, driven by motors varying in rating from 200 to 50 horse-power. These are of the main-and-tail type, driven mostly by slow-speed, single-reduction gears, though in some cases double-reduction gearing has been necessary. The speed is about six miles an hour. A flexible coupling between the motor and gearing absorbs the shock of starting. These gears have proved to be reliable and easy to control. The underground pumping is now done by motors driving three-throw and high-lift centrifugal pumps. At one pit an Ilgner hoisting set has been installed which will raise 1,800 tons of coal a day. The ventilating fans are driven by motors, as these furnish a most desirable load. In one case there is a Sirocco fan capable of handling 300,000 cubic feet of air a minute, driven by two 300-horse-power motors, through ropes. Several similar, though smaller, fans are being installed. There is a complete telephone system connecting the generating station with the switching and transformer stations. The various mine shops have also been converted to the electric drive.—*Electrical Review (London), July* 31.

The Michigan Central's Detroit Tunnel.

One of the largest and most important projects in railroad engineering now being carried on in this country, and of which very little has been publicly said and written, is the construction of the Michigan Central's tunnel under the Detroit River at Detroit. At the present time it is about one-half completed; it is expected to be in operation by July, 1909.

Approximately one and one-half miles in length, exclusive of approaches, it will form the connecting link from Detroit to Windsor, Canada. Its cost is estimated at $15,000,000, to which must be added the cost of a new terminal at Detroit and the remodeling of the one at Windsor.

The tunnel is being constructed by the engineering firm of Butler Brothers & Hoff, under the supervision of the Detroit Tunnel Company.

The remarkable feature of the construction work is that it is being carried on according to lines entirely new. The old method of submarine tunnel construction—that of building the tube piece by piece under water by means of compressed air—has been entirely ignored. The method in use consists of building the sections at St. Clair, a point about twenty miles north of Detroit, and towing them on barges to the point at which they are to be sunk.

The sections are then permitted to fill with water and sink to a bed prepared for their reception. They are then united by divers by means of riveted flanges. This being done, the whole is enclosed in concrete, which solidifies and acts as a preservative against corrosion of the metal and protection against flooding.

The water is then drawn out by siphons, and the end tube bulkheaded, after which nothing remains but the interior work, such as the laying of a concrete roadbed, the laying of rails and conduits, etc.

The tubes, two in number, are laid side by side, one to accommodate westbound traffic, the other eastbound. The motive power will be electricity transmitted in much the same manner as that in use on the New York Central to White Plains.

Officials of the Michigan Central are confident that the project will earn its cost several times over. In the first place, the road could never be considered first-class in every particular until the present method of moving passengers and freight across the river—by ferry—is abolished. The ferriage of trains now involves a delay of from thirty minutes to almost anything, depending upon the amount of ice which, during the winter, often clogs the river.

The 1908 Electric Lighting and Illuminating Engineering Number.

The annual Electric Lighting and Illuminating Engineering Number of the ELECTRICAL REVIEW will be published September 12. This issue will be replete with interesting articles by the leading authorities in the electric lighting field, and will bring down to date authentic information concerning the development of the electric lighting industry and the present-day ideas of illuminating engineers. Some of the leading articles already scheduled are as follows: "Progress in Incandescent Lamp Development," by the engineering department of the National Electric Lamp Association and the incandescent lamp engineers of the various interests manufacturing incandescent lamps; "The New Westinghouse-Nernst Lamps," by Otto Foell, chief engineer of the Nernst Lamp Company; "Progress of Cooper Hewitt Lamps," by Dr. J. Polak; "The Kusel Colloid Lamp," by Paul McJunkin; "The Helion Lamp," by Professor H. C. Parker and W. G. Clark. Bassett Jones, Jr., contributes a masterly article treating in a philosophic vein the relations of the architect and the illuminating engineer. This article is entitled "The Illuminating Engineer as an Architectural Critic." An article entitled "The Illuminating Engineer" is contributed by Albert J. Marshall, chief illuminating engineer for the Bureau of Illuminating Engineering, New York city. Our London correspondent, A. H. Bridge, whose symposium on English conditions, published last year, attracted so much attention, will contribute a review of the conditions in electric lighting and illuminating engineering in Great Britain. In addition there will be an unusually comprehensive presentation of data concerning recent developments in flame arc lamps, tube lighting, the newer forms of incandescent units, carbon arc lamps, central station apparatus, and descriptive and illustrated matter concerning the manufacture of incandescent lamps.

So great was the interest manifested in the first Electric Lighting and Illuminating Engineering Number, published September 14, 1907, that although a greatly enlarged edition was printed, this was exhausted within a short time after the date of publication. In order to facilitate the distribution of the 1908 edition, it is requested that those desiring extra copies will send in their orders to the office of the ELECTRICAL REVIEW at once.

INTERNATIONAL ASSOCIATION OF MUNICIPAL ELECTRICIANS.

THIRTEENTH ANNUAL CONVENTION, HELD AT DETROIT, MICH., AUGUST 19-21.

The thirteenth annual convention of the International Association of Municipal Electricians was opened at the Hotel Pontchartrain, Detroit, Mich., by President R. A. Smith at noon on Wednesday, August 19. An address of welcome was delivered by Mayor William B. Thompson, and was responded to on behalf of the association by J. B. Yeakle, of Baltimore, Md.

An address by Past-President Hatch closed the morning session.

The afternoon session was opened at 1.30 and the president, R. A. Smith, then delivered the presidential address and also read a paper on "The Moving-Picture Hazard.".

There is nothing of late years that has given the insurance companies more concern than the moving-picture business. The rural districts and small towns of many states are overrun with these shows, many of which are a menace to the community owing to lack of observance of the rules of the National Code. Many of these shows use machines without magazine, booth or other approved mechanisms. In the light of what has happened, it seems criminal for those in authority to ignore these conditions. The National Code contains a rule, No. 65a, which, if followed to the letter, will eliminate the greatest danger, but there are many other precautions necessary, such as licensing the operatives of the machines, proper wiring, ample exits and red lights. Various interpretations have been put upon Rule 65a as regards the proper material for the fireproof booth. The rule plainly reads "fireproof material" and means "fireproof material" such as will not warp when heated and will stand the wear and tear that booths are subjected to. Mr. Smith called attention to the rules and precautions taken by his city of Norfolk, Va. They are as follows:

"Whenever moving-picture machines are operated in any building or tent within the city limits, they shall be so located as not to obstruct the exits, aisles or passages thereto, and shall be placed in a metal chamber of galvanized iron not less than No. 24 gauge, said chamber not to be smaller than six feet square by five and one-half feet high, inside measurement. There shall be an inner and outer wall with a two-inch air space between, for sides and top, all to be riveted to a substantial iron framework. There must be a vent pipe not less than twelve inches in diameter run from metal chamber to a point outside building. Main door must be hung by stout coiled spring hinges and swing outward; openings for lens and operator must not exceed ten inches by eight inches each, and have metal drop shutters running in metal grooves, shutters to be held open by light cotton strings passing across inner ceiling of booth, through side of booth to outside. All wiring in both to be in conduits; wiring for picture machine to be separate from lighting system; all exits to have large signs and red lanterns, burning sperm oil; not less than two five-gallon chemical extinguishers to be located near booth. All machines to be in charge of competent men who shall receive a certificate from the Board of Control, said certificate to be good for only one year and revocable for cause."

Discussing this paper O'Hearn, of Cambridge, Mass., and Jerry Murphy, of Cleveland, both remarked that a larger part of the hazard from moving-picture machines was not that caused by electrical means, but resulted from causes entirely distinct. It would seem that the proper department to place the inspection was the fire department.

C. R. George, of Houston, Tex.; W. Y. Ellett, of Elmira, N. Y.; W. M. Petty, of Rutherford, N. J., and others commented upon the paper and agreed for the most part with the author.

The first paper read and discussed at the second day's session was that by W. M. Petty, of Rutherford, N. J., on "Batteries for Signaling Systems." Mr. Petty reviewed the various types of cells used for signaling work and mentioned their advantages and disadvantages. The preparation of this paper was undertaken, primarily, to provoke discussion on the storage cell, which is, par excellence, the battery for the city electrician. It can be used for any kind of work, either open or closed circuit, and, with a minimum of care and expense, can be relied upon at all times to produce a steady flow of current.

Of late years the greatest objection urged against the storage cell, that of the means for charging, has been removed, and every place, no matter how small, now has an electric light or power circuit available. Even those places where no direct current can be secured, can, by means of simple and efficient devices, convert the alternating current to direct, and thus charge the cells at a low cost.

In investigating the storage battery when used for signaling work, Mr. Petty finds by far the larger majority are the six-ampere-hour, two-plate type. The twelve-ampere-hour cell is also much in use and is increasing in popularity.

With the latest type of switchboard made by the leading manufacturers of fire-alarm and police apparatus, the cells can be grouped so as to obtain the greatest advantages from the charging current, and they can be also controlled so as to render the operations almost automatic.

The methods of charging range from direct current at 600 volts down to 110 volts, and alternating current from 220 volts and 110 volts, converting by means of motor-generator and rectifier sets down to four volts.

The cost of maintenance varies widely. Out of the many systems examined by the writer, a large majority obtain the necessary current free of charge; others pay rates varying from five to fifteen cents per kilowatt-hour, making the average cost per cell vary from ten to fifty cents per annum. In places using alternating current the efficiency of conversion varies from twenty-five to sixty-five per cent.

Mention was made of a plant the author had installed wherein he had used the mercury arc rectifier for charging the cells. This plant has been running since June, 1907, and has shown very satisfactory results. No trouble whatever has been experienced with it, and the cells are in every respect as good as when first installed. The prediction that some trouble and expense would be experienced in the operation of the tube has been proven a fallacy. As a matter of fact, the original tube, started June 15, 1907, is still in operation and shows no signs of failing. It has given over 1,100 hours' service. This installation shows an efficiency of sixty-two per cent and is run at about one-third the capacity of the rectifier.

In the resulting discussion Jerry Murphy, A. C. Farrand, C. R. George, T. C. O'Hearn, C. P. Diehl and J. B. Bernstein participated.

The matter of overcharging was touched upon, and it was shown that in the majority of cases overcharging is a very common practice. The life of the cells, even though they may be much overcharged, seemed to be in excess of six years and an instance where a cell had been in use for nine years was mentioned.

Jerry Murphy, of Cleveland, Ohio, then read a paper on "Police Telegraph Systems." This was a general paper intended to prove the value of such systems to the community, and not taking up the question technically. This side of the problem was, however, brought out in the discussion and it was shown in many cases that a combination of the telephone and telegraph was essential to a proper system.

An elaborate paper on "Methods of Fault Location," by J. B. Bernstein, illustrated by diagrams and apparatus, was read and discussed. Mr. Bernstein reviewed the various methods of testing by means of the many forms of Wheatstone bridge and gave simple instructions regarding them.

Mr. Petty, in opening the discussion, said that the thanks of the members were due Mr. Bernstein for his very practical paper.

C. R. George's paper, on "Electrical Equipment of a Fire Station," described a system in use in the city of Houston, Tex.

The third day's session was devoted to committee reports and routine business.

The chairmen of the various departments of the organization submitted their reports, showing the progress that had been made during the year.

A resolution was passed appointing a committee of three to report on the proposed action of the United States Post-Office Department regarding the painting red of mail boxes. This committee has power to enter a protest in the name of the association against such action on the ground that it would tend to cause confusion, red being the standard color for fire-alarm signal boxes.

It was decided to hold the next convention at Atlantic City, N. J.

The secretary, F. P. Foster, was elected a life member in recognition of his excellent services to the association.

Many entertainment features were provided for the ladies and the members. The afternoon of Friday was spent on one of the river boats, with luncheon at the Casino through the courtesy of Gamewell Company.

The election of officers resulted as follows:

President—J. B. Yeakle, Baltimore, Md.

First vice-president—W. S. Devlin, New Castle, Pa.

Second vice-president—H. C. Bundy, Watertown, N. Y.

Third vice-president—F. A. Cambridge, Winnipeg, Manitoba.

Fourth vice-president—C. R. George, Houston, Tex.

Secretary—Frank P. Foster, Corning, N. Y.

Treasurer—C. P. Diehl, Harrisburg, Pa.

Executive committee—A. C. Farrand, Atlantic City, N. J.; C. A. Sundquist, Jamestown, N. Y.; L. L. Kingsbury, Baltimore, Md.; C. F. Gall, Louisville, Ky.; S. W. Manning, St. Paul, Minn.; T. C. O'Hearn, Cambridge, Mass.; R. A. Smith, Norfolk, Va.; William Crane, Erie, Pa.; John O'Brien, Fond du Lac, Wis.

Finance committee—Jerry Murphy, Cleveland, Ohio; A. L. Kittridge, New Haven, Ct.; A. L. Pierce, Wallingford, Ct.

The following committees were also appointed: Inspection—L. L. Kingsbury, R. A. Smith, T. C. O'Hearn. Police Signal—A. C. Farrand, Jerry Murphy, A. L. Kittridge. Fire Telegraph—C. F. Gall, S. W. Manning, H. C. Bundy. Electric Light—C. A. Sundquist, A. L. Pierce, F. A. Cambridge. Outside Construction—W. S. Devlin, William Crane, John O'Brien.

Among those registered were the following:

W. A. Devlin, New Castle, Pa.; C. R. George, Houston, Tex.; A. C. Farrand, Atlantic City, N. J.; A. S. Hatch, Burnside, Ky.; R. A. Smith, Norfolk, Va.; F. P. Foster, Corning, N. Y.; E. J. Hunt, New York city; L. L. Kingsbury, Baltimore, Md.; P. H. McMannus, Wilkesbarre, Pa.; C. F. Gall, Louisville, Ky.; A. C. Friend, Chicago, Ill.; R. C. Smith, New York city; R. J. Thorne, Chicago, Ill.; M. J. Donoghue, Niagara Falls, N. Y.; W. F. Wills, Niagara Falls, N. Y.; A. L. McKittridge, New Haven, Conn.; A. J. Bell, New Rochelle, N. Y.; H. C. Bundy, Walkertown, N. Y.; W. L. Kent, Lynchburg, Va.; C. P. Diehl, Harrisburg, Pa.; C. G. Sundquist, Jamestown, N. Y.; P. J. Kern, Louisville, Ky.; William Crane, Erie, Pa.; J. B. Diller, Memphis, Tenn.; Ira B. Yeakle, Baltimore, Md.; Anna Veath, Youngstown, Ohio; John Berry, Indianapolis, Ind.; Adam Bosch and Mrs. Bosch, Newark, N. J.; E. Darrow, Cincinnati, Ohio; S. W. Manning, St. Paul, Minn.; John O'Brien, Fond du Lac, Wis.; F. E. Stover, Chicago, Ill.; J. H. Warren, New Brunswick, N. J.; J. B. Bernstein, Philadelphia, Pa.; J. O. Dormer, Chicago, Ill.; J. E. Clark, Rutherford, N. J.; J. W. Whaling, Chicago, Ill.; J. B. Yeakle, Baltimore, Md.; J. C. Craig and Mrs. Craig, Toronto, Ontario; Mrs. J. L. Simpson, Washington, D. C.; C. S. Downs and wife, Altoona, Pa.; N. M. Loomis, Akron, Ohio; E. J. Loomis, Allegheny, Pa.; Ambrose Perkins, Youngstown, Ohio; W. M. Petty, Rutherford, N. J.; Mrs. P. Gykern, Louisville, Ky.; Mrs. C. Hall, Knoxville, Tenn.; Mrs. W. M. Crane, Erie, Pa.; Mrs. J. Bell, New Rochelle, N. Y.; Flora E. Hatch Detroit, Mich.; Mrs. A. Perkins, Youngstown, Ohio; Mrs. F. Quimby, Youngstown, Ohio; Fred Quimby, Youngstown, Ohio; Albert Murphy, Cleveland, Ohio; Edward Murphy, Cleveland, Ohio; Jerry Murphy, Cleveland, Ohio; F. A. Cambridge, Winnipeg, Manitoba; W. Y. Ellett, Elmira, N. Y.; T. C. O'Hearn, Cambridge, Mass.; Charles S. McCoskar, Mobile, Ala.; H. A. Bowen, Cleveland, Ohio; Mrs. A. J. Cowles, Detroit, Mich.; Lucy Peterson, Detroit, Mich.; J. W. Brooke, Cleveland, Ohio; Miss M. Buckley, Brooklyn, N. Y.; Miss K. Buckley, Brooklyn, N. Y.; Miss Stella Buckley, Brooklyn, N. Y.; F. B. Mistrosky, Detroit, Mich.; Ion Simonds, Charleston, S. C.; J. B. McCarthy, Detroit, Mich.; A. E. Braddell, Chicago, Ill.; S. C. Harvey, Chicago, Ill.

The following companies had exhibits:

Stanley & Patterson, New York city—Wireless battery holders, "Faraday" bells, etc.

Hartford Time Switch Company, Hartford, Ct.—Hartford time switches.

De Veau Telephone Manufacturing Company, New York city—Switchless telephones, etc.

Gamewell Fire Alarm Telegraph Company, New York city—Successive fire-alarm boxes, punching registers.

Duplex Metals Company, New York city—"Monnot" copper-clad steel wire.

Leeds & Northrop Company, Philadelphia, Pa.—Electrical measuring instruments.

P. R. Manufacturing Company, Detroit, Mich.—Electric bells, etc.

Frank B. Cook, Chicago, Ill.—Telephone protection apparatus.

Corwin Telephone Manufacturing Company, Chicago, Ill.—Telephone apparatus.

Gould Storage Battery Company, New York city—Storage batteries for signaling systems.

Reorganization of the Mohawk Valley Company.

The Public Service Commission, Second District, has passed upon the preliminary applications in the financial reorganization plan of the Mohawk Valley Company, the holding company of the so-called Vanderbilt or Andrews syndicate electric railroad and lighting properties.

Prior to the enactment of the Public Service Commissions law the Mohawk Valley Company could lawfully acquire and hold stock of railroad and lighting companies to an unlimited amount. Its operations have been conducted upon the assumption that this right continued in the control and management of the companies in which it owns a majority of the stock and the financing has been carried on upon this assumption.

Section 54 of the Public Service Commissions law provides that where stock shall be transferred or held for the purpose of collateral security, no stock corporation of any description, domestic or foreign, other than a railroad corporation or street railroad corporation, shall purchase or acquire, take or hold, more than ten per centum of the total capital stock issued by any railroad corporation or street railroad corporation, or any other common carrier.

Under this provision of statute the Mohawk Valley Company was required to change its method of financing, and it has been found necessary to devise other measures for the handling of its property. An extensive scheme of reorganization, which involves a series of applications to the commission, has been worked out. The plan involves a series of complicated changes in the handling of stocks and the amount thereof of the various companies concerned in the transaction.

The essential feature of the plan when it is entirely consummated is that there shall be no more securities afloat than now and that there shall have been accomplished no increased issue of stocks or bonds. The end to be attained is a change in the ownership of stocks so that the financial operations of the various companies may be placed in harmony with the existing law. The whole scheme has been informally submitted to the commission for its opinion.

The companies in which the Mohawk Valley Company is interested and its holdings are as follows:

Name of Company.	Amount Outstanding	Mohawk Valley Amount.	Co. Owns per ct.
Utica & Mohawk Valley Railway Co.	$7,500,000	$7,500,000	100.00
Oneida Railway Co.	*1,923,000	1,922,700	99.98
Syracuse R. T. Railway Co.	†3,918,071	2,317,500	59.14
Rochester & Eastern Rapid Railway Co.	1,500,000	1,500,000	100.00
Schenectady Railway Co.	4,100,000	2,050,000	50.00
Rochester Elec Railway Co	200,000	173,900	86.95
Rochester & Suburban Railway Co	420,000	400,800	95.42
Rochester & Sodus Bay Railway Co.	1,850,000	1,100,000	59.45
Ontario Light & Traction Co	100,000	100,000	100 00
Rochester Railway Co	6,000,000	900	.03
Rochester Railway & Light Co.	9,498,860	7,638,900	80.41
Canandaigua Railway & Gas Light Co.	50,000	20,550	41.00
Eastern Monroe Electric Light & Gas Co.	250,000	250,000	100 00

* $77,000 owned by Oneida Railway Co

† $81 928.26 owned by Syracuse Rapid Transit Railway Co

The net result of the changes involved is that instead of owning the surrendered capital stock of the Mohawk Valley Company the New York Central & Hudson River Railroad Company will be the owner of stocks to the amount of $10,230,480, and that instead of holding the indebtedness against the Mohawk Valley Company of $4,500,000, it would be the owner of the capital stock of the Rochester Railway Company of the par value of $2,998,700 and of the assumed value of $4,500,000. This action is approved, the commission insisting that it must, "however, be clearly understood that this action of the commission is not to be construed as an unqualified approval of the results to which it assents. The commission finds itself confronted with a situation arising out of a change of law. That change of law compels a change of corporate relations. To some change it must assent in order to preserve properties under its supervision in a condition to meet the public requirements which they were created to serve. It deems that wise policy and a just regard both for the public and private interests involved require it to authorize that course which within the law best meets the exigencies of the situation, although it might be as an original proposition disconnected from existing investments, legal at the time they were made, it would unhesitatingly stamp that course with its disapproval. The new restrictions upon corporate dealings should be applied to existing investments with sense and judgment, and that has been the endeavor in this case."

The application of the Rochester & Eastern Railway Company is for the consent of this commission to increase its capital stock from the sum of $1,500,000 to $15,290,200, thus making an increase in the amount of its common capital stock in the sum of $13,790,200.

There is nothing in the present condition of this company, if it be considered by itself, which demands for the purposes of its successful operation as a railroad that its capital stock be increased. For reasons it has been selected, however, as a company which shall become the owner and holder of certain other railroad stocks which must be placed somewhere under the proposed scheme relative to the holdings of the Mohawk Valley Company. This application is granted.

The next step is to be as follows: The consolidating company succeeding to the Rochester & Eastern Rapid Railway Company would be the owner of the total capital stock of the Oneida Railroad Company and the Utica & Mohawk Valley Railroad Company, except the amount of $300 of the Oneida Railway Company, which it is proposed to acquire. Upon the acquisition of this stock by the consolidated company, it then being the owner of the total capital stock of the two companies, it is proposed to merge the same with the consolidation, pursuant to the provisions of the statute in that behalf, and thus extinguish the two companies and reduce the number of companies to three, namely, Schenectady, Syracuse Rapid Transit and the Consolidated.

This completes the series of operations definitely projected, although it is clearly understood that these applications are granted upon the express understanding that it is contemplated by the applicants to consolidate and merge the companies, and to place a general refunding mortgage upon the property of the consolidated company, and that these applications are granted for the express purpose of bringing about the final results as indicated.

"The commission grants these applications in view of all the reasons presented to it in connection with the entire series of transactions. It might hesitate seriously to grant these applications were the proceedings to stop with them and nothing further be done. It realizes that it has no powers to compel the consolidation or the merger, and that these acts will take place depends upon the good faith of the parties, which is pledged to the same, and of which pledge these remarks are to remain as the evidence." Upon the theory that this is the proper way in which to handle the financial operations of all the consolidated companies, it is believed that a better market can be found for bonds which are secured by all of the properties than for bonds which have a security upon the property of one company alone.

The opinion written by Chairman Stevens holds:

1. That the situation of all the companies involved justified and required a change in the stock holdings.

2. That the change in the law compelled a change in the corporate relations.

3. That wise policy and a just regard for both the public and private interests affected required the commission to authorize such reorganization as within the law best meets the exigencies of the situation, although the results may be such that as an original proposition disconnected from existing investments, legal at the time they were made, it would unhesitatingly stamp them with its disapproval.

4. In any inquiry into the rates and charges of a public service corporation, that portion of its capital stock issued for the purpose of owning and holding the stocks of other corporations is not a factor to be considered. Upon such an inquiry if the capital stock of the corporation is an element to be considered, only that portion of the capital stock which may be said to represent the property operated is entitled to be regarded.

5. Capital stock will not be permitted to issue for the purchase of the stock of other corporations unless the stock to be purchased has a value substantially equal to the par value of the stock to be issued. The protection of ignorant or improvident persons against stock issues representing fictitious values requires this rule.

The Character of Corporate Stocks Discussed—They are considered to be evidence of right to an aliquot part of the corporate assets upon final dissolution and division and of the right to the same part of any dividend which may be declared. The so-called par value furnishes no indication of the true value of the property to which the stocks are mere evidences of title or the dividend-earning power of the same.

THE TEST-METER METHOD OF TESTING SERVICE METERS—III.

BY JOSEPH B. BAKER.

THE MOWBRAY TEST METER, PRESENT FORM—GENERAL FEATURES.

The Mowbray test meter is now made in improved form in both direct-current and alternating-current types.[1]

The improvements consist in a refinement of the device described in the preceding article whereby the "sight method" of reading the test meter is simplified and facilitated; in better arrangements for making connections and for starting and stopping the test meter; and in superior flexibility, portability and general handiness of the test meter as a whole.

The construction and operation of this type are based on the alternative method of testing referred to in the preceding article, in which readings of a pointer and scale attached to the test meter are compared with a determined number of revolutions of the consumer's meter under test. By the simple plan of starting and stopping the test meter electrically, however, it is made practicable for a single observer to perform the tests, instead of requiring a tester and a helper as in the use of the earlier type.

Fig. 3 is a general view of the latest type of Mowbray direct-current test meter, and Fig. 4 is a diagram of the potential circuit and of the methods of making running and heating connections.

THE DIRECT-CURRENT TEST METER.

The direct-current test meter consists of a modified, inverted commutator meter having two potential circuits and a composite field-winding, and a diamond cup-jewel step bearing and sapphire ring-stone top bearing, and is mounted in a carrying case, with soft rubber cushions to absorb vibration.

Mr. Mowbray states that the composite field-winding in the present form of test meter is designed to facilitate the accurate adjustment of the ratio between the windings by arranging the individual coils so as to make energy field (as a whole) of the same mean diameter, or in other words bring the average distance of the turns in each field of the composite winding the same distance from the armature as the average distance of the turns of every other field. In the 1902 form of composite winding, in which each pair of coils constituting a field was symmetrically arranged (one on either side of the armature) with the smaller-wire coils on the outside, it was a matter of lengthy experiment to determine the right number of additional ampere-turns to add to the outside coils in order to compensate for

Fig. 3.—Latest Type of Mowbray Direct-Current Test Meter.

the greater mean distance of this coil from the armature. In the present form the mean diameter of the two coils constituting each field is made equal to the mean diameter of the entire composite winding, by making one of the two coils

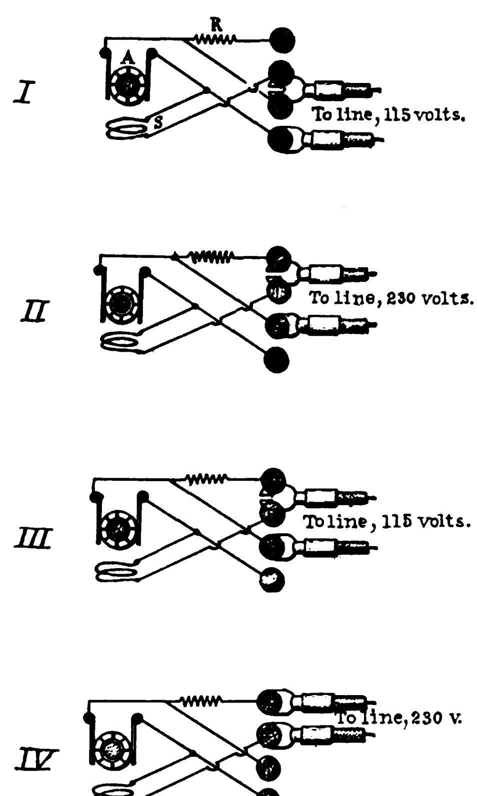


Fig. 4.—Diagram of Potential Circuit and Method of Making Running and Heating Connection.

smaller in diameter and the other an equal amount larger in diameter, than this mean. Thus, in a composite winding consisting of one-ampere, four-ampere, sixteen-ampere and eighty-ampere fields, the group of coils on one side of the armature would consist of an eighty-ampere coil (innermost) having a sixteen-ampere coil wound over it, then a four-ampere coil, and lastly (outside of these three) a one-ampere coil; whereas the group of coils on the other side of the armature, in order from innermost to outermost, would consist of one-ampere, four-ampere, sixteen-ampere and eighty-ampere coils.

Another feature of the present composite field-winding is that the available wire is used to best advantage by including the coarser coils in circuit with the finer ones in progressing from the highest-value field to the lowest. Thus, in the four-field test meter referred to the eighty-ampere field consists of the one pair of eighty-ampere coils already described, *viz.*, the innermost coil of the group on one side of the armature and the outermost coil of the group on the other side; but the sixteen-ampere field would include not only the pair of sixteen-ampere coils but also (in series therewith) the pair of eighty-ampere coils; the four-ampere field would comprise the four-ampere, sixteen-ampere and eighty-ampere coils, and the one-ampere field the one-ampere, four-ampere, sixteen-ampere and eighty-ampere coils.

The preceding arrangement, which obviously occupies the minimum amount of space for a given field strength, superseded a bulkier and more complicated form of composite field-winding comprising eighty-ampere, twenty-ampere, four-ampere and one-ampere "scales" in which a commutating switch, mounted on an insulating drum and operated by a knurled knob, was used to make the different combinations. The test meter illustrated in Fig. 5 and Fig. 6 is equipped with this arrangement and also with the telephone device described in the preceding article. The eighty-ampere scale was cut in, on this switch, by connecting four twenty-ampere coils in parallel, and the twenty-ampere scale by connecting these coils in series; and the four-ampere scale was cut in by connecting four one-ampere coils in parallel, and the one-ampere scale by connecting these one-ampere coils in series.

In some of the Mowbray test meters a brass upper bearing was used. The bearing hole was countersunk at the lower end of the bearing plug, to prevent the shoulder of the meter shaft from battering the plug—as by the up-and-down motion of the rotating element in carrying the test meter in an inverted position (see Fig. 2[1])—in such a way as to cause binding on the shaft. Modern test meters of the type exemplified in Fig. 3 and Fig. 6 are carried right side up and have a "locking device" for keeping the rotating element out of contact with the jewel in transportation.

The case is provided with a hard rubber top on which are mounted binding-post terminals of the various field and potential windings to facilitate making the various warming-up and running connections, to-

[1] The alternating-current test meter illustrated herewith is designed with 1.5, fifteen and 150-ampere current coils, for 115 and 230 volts, sixty cycles. The direct-current test meter illustrated is designed with one, four, sixteen and eighty-ampere current coils, for 115 and 230 volts. Alternating-current and direct-current test meters of just one-half the above current capacities are also made; also a direct-current meter with one, three, ten and thirty-ampere coils.

[1] Page 236, Vol. 53, No. 7.

gether with a pair of knurled heads for adjusting the friction-compensating coil without removing the meter from the case, and a small level. The usual meter register is omitted and a horizontal "dial," which is observed through a window in the hard-rubber top, is provided instead. The dial consists of a large circular scale, divided into 100 scale divisions, swept by a pointer fixed to the upper end of the meter shaft, and a smaller circular scale having ten scale divisions and with a pointer geared to the shaft in the ratio of 10 to 1, so that for every revolution of the pointer on the large scale the pointer on the small scale moves through one scale division.[1] In the lower part of the case is located a small window for observing the condition of the commutator. In the form illustrated the meter itself is not equipped with a switch for starting and stopping, this switch being inserted in the current leads.

This direct-current test meter is claimed to possess an exceedingly high torque—about double that of an ordinary small consumer's meter—secured by increasing the number of turns in both the field and armature windings, and by omitting from the 115-volt potential circuit the usual series resistance and applying the total voltage direct to the armature and friction compensating coil in series.

THE ALTERNATING-CURRENT TEST METER.

A recent type of alternating-current test meter consists of a modified induction meter mounted in a carrying case and equipped with many of the general features of the direct-current test meter. In the hard-rubber top are current and potential binding-posts, a single knurled switch for adapting the potential circuit for 115 to 230 volts, a small level, a push-button switch for starting and stopping the meter by closing and opening the potential circuit, and the window for observing the dial.

Testing with the present form of test meter, of either the direct-current or alternating-current type, requires only one man, because the test meter, which is used after the manner of a stop-watch, constitutes the only piece of test apparatus used. The starting and stopping, however, are not accomplished mechanically, as in a stop-watch, but electrically by means of the switch, which throws the test meter in or out of circuit. After making the necessary connections to the service wires at the consumer's meter the test meter is simply switched into circuit during the time required by the consumer's meter to make a determined number of revolutions, noted in the usual way by observing a mark on the disc, and out of circuit again at the end of this interval. The switching is effected in the direct-current type

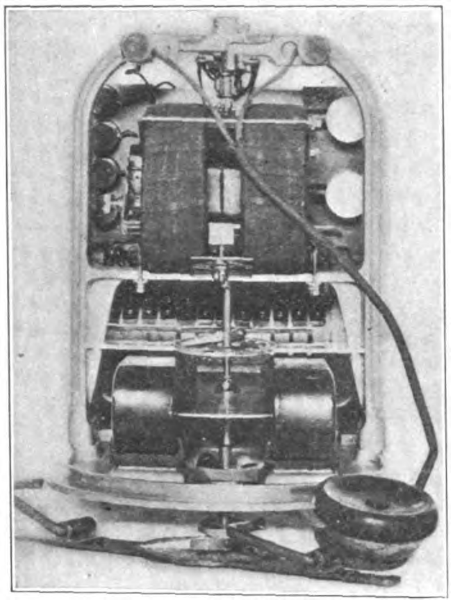

Fig. 5.—Mowbray Alternating-Current Test Meter.

by cutting in the series fields on the load, and in the alternating-current type by closing the potential circuit across the voltage. Obviously no appreciable net error is introduced by this start-and-stop method of comparing the test meter with

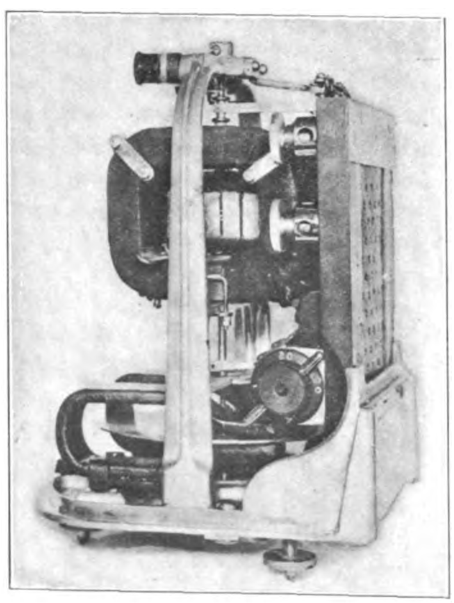

Fig. 6.—Mowbray Alternating-Current Test Meter.

the consumer's meter, as the lag of the disc in starting, due to its inertia, when the test-meter switch is thrown on is compensated for by the overrunning of the disc, restrained by the braking magnets, after the switch is thrown off.

In the direct-current test meter, normal running temperature (and consequent accuracy) is reached by the application of double voltage to the test-meter potential circuits in series, or of normal voltage to the potential circuits in parallel, for a period of two and one-half minutes. This increased time, as compared with the one and one-half minutes required for the armature of the first model to heat, is due to the fact that the new model armature is specially wound with a much greater number of turns. In the diagram of Fig. 4, I shows the connections for heating the 115-volt circuit in two and one-half minutes on 115 volts; II, the connections for heating the 115-volt circuit in two and one-half minutes on 230 volts; III, the 115-volt running connections, and IV, the 230-volt running connections. Normal voltage is then applied and the potential circuit is allowed to remain undisturbed until the completion of the test, as any interruption of this circuit would allow it to cool down and render the test meter for the time inaccurate. For this reason the operating switch of the direct-current test meter is, as already stated, located in the *current* circuit (see Fig. 3). The operating switch is constructed so as to cut the field windings in and out without at any time opening the main circuit or causing arcing.

In the alternating-current test meter the operating switch is, as already stated, in the *potential* circuit. The fact that voltage is not applied all of the time causes no inaccuracy because, as in ordinary induction meters, the temperature and resistance, and hence the accuracy, vary but slightly with respect to the length of time that the voltage is applied.

Electrical Supplies for the Navy Department.

The Bureau of Supplies and Accounts will open bids in Washington, D. C., on September 1 for two sets of wireless telephones for delivery at Brooklyn, N. Y.; for miscellaneous rubber-insulated cable for delivery at Washington, D. C.; for 6,450 feet of telephone cable for delivery at Boston, Mass. On September 8, for 100,000 feet of ship lighting cable, for delivery at Brooklyn, N. Y.; for miscellaneous electrical supplies for delivery at Boston, Mass. On September 15, for 800 feet of rubber-insulated cable, 6,600 conduit clamps and six transformers for delivery at Mare Island, Cal.

RAIL CORRUGATION.[1]

BY PROFESSOR C. A. CARUS-WILSON.

It will not be necessary for me to spend time in giving any general account of rail corrugation; the phenomenon is, unfortunately, only too well known to all those interested in tramways. I will therefore begin by asking you to consider certain facts which may throw light on the vexed question as to how corrugations are formed.

You have no doubt observed that corrugations on grooved rails are very often accompanied by a cutting of the check of the rail immediately opposite. This is especially noticeable on curves, where the centrifugal force has made the inner flange bear against the inner check, the corrugations being on the outer rail. But the same kind of check-cutting is found on the straight, where the car has been bearing over on one side or the other, the corrugations appearing on the rail immediately opposite the one whose check is cut. Speaking generally, it may be said that, with some exceptions, to which I will allude later on, corrugation is accompanied by a cutting of the check of the opposite rail.

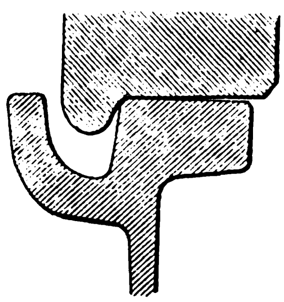

Fig. 1.—New Wheels and Rails.

When wheels and rails are new there is a clearance, generally of about one-quarter inch, between the flange and the check on both sides, as shown in Fig. 1, which represents the normal position of the flange in the groove on each side when new. Any side pressure on straight or curve is then taken by the throat of the flange bearing on the head of the rail. The flange can not come in contact with the check until considerable wear has taken place. Fig. 2, taken from a cast of an actual tire, shows how the flange bears against the check when the flange has worn sufficiently. Such instances of check-cut tires are very common.

I do not now propose to pursue the important inquiry as to how this wear is brought about, as this would involve a discussion of the whole problem of wheel wear; but, taking the fact that check-cutting generally accompanies corrugation, to consider the question as to the possible connection between the two. The answer to this question depends upon the solution of a very much wider question, *viz.*, when a wheel rolls upon a flange how is the motion affected by the grinding of the flange against the head of the rail? With a view to investigating this matter I have constructed a model which consists of a four-wheel truck with brass wheels two and one-half inches diameter, whose centres are four and one-quarter inches apart. There is an equalizer suspension by which a weight, hung from a central support, is distributed equally over the four wheels. One wheel on each axle is keyed to the shaft, the other being a loose wheel held in place by a sleeve. The left of these loose wheels has its sleeve slotted to correspond with a slot in the end of the axle; into this slot can be placed a plate or coupler which at the same time fits into a stud in the rim of the wheel. When the coupler is fixed in position the wheel is thus coupled to the axle. Different couplers may be used, some being rigid and some of the nature of a stiff spring. There is a mark on the rim of the coupled wheel which may be set opposite to any required point on the rail. The track consists of brass rails, three-sixteenths inch wide and three feet long, set to a gauge of three and nine-sixteenths inches, with a space between them to admit of the passage of the suspension for the weight.

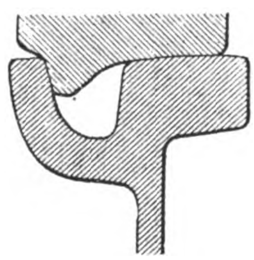

Fig. 2.—Showing Worn Flange Bearing Against Check.

The truck is first loaded with a weight of fourteen pounds, a rigid coupler inserted in the loose wheel, and the mark set opposite a point A at the right-hand end of the track. The truck is then gently pushed from behind and made to travel over the track until the wheel has made three complete revolutions and the mark has met the rail at a point B. The distance AB then represents a pure roll equal to three times the circumference of the wheel. The truck is taken back and the mark placed opposite point A as before. If the flange of the coupled wheel is now pressed hard against the rail while the truck is made to travel forward, it is found that the mark will meet the rail at a point C which lies beyond point B, the distance BC being about two per cent of AC. Owing to the side pressure the flange bites the rail on a line of contact whose diameter is greater than that of the tread of the wheel; the wheel tends to run on this line of contact, and the tread is forced to skid on the head of the rail in consequence. The result is that the motion is a combined roll and skid, the distance AB representing roll and BC representing skid. The skidding, however, is continuous, and for any part of AC covered, say the hundredth of an inch, the same proportion, *viz.*, two per cent. is skid. The two wheels, being rigid on one side, both skid an equal amount.

It thus appears that when the flange is forced against the side of the rail the wheels are made to skid a certain percentage of the distance traveled. Having ascertained this fact, the next step was to find out whether any such skidding took place on an actual tramway track. For this purpose I conducted a series of tests at Croydon on a car placed at my disposal by T. B. Goodyer, general manager of the Croydon Corporation Tramways.

The car selected for the tests was a four-wheel double-deck car with Mountain & Gibson truck equipped with two Westinghouse No. 200 motors, weighing, with five passengers, 7.8 tons. The truck had a wheel base of six feet, with British Griffin chilled-iron wheels. A bicycle gear-wheel with sixty-eight teeth was fixed on one of the axles and connected by a chain-drive to a spur-wheel with fourteen teeth secured on the floor of the car. A Harding speed counter was attached to the spur-wheel, by which the revolutions of the axle could be measured. The circumference of each wheel on this axle was measured with a steel tape, and checked by calipering, the result being exactly ninety-five and three-quarters inches in each case, the two wheels having the same diameter.

A section of straight and nearly level track was chosen on the road between Croydon and Purley. There are here two lines of rails, badly corrugated for the greater part of the distance. The track is of standard gauge with macadam sides, and the rails, weighing ninety-five pounds per yard, are laid on a six-inch bed of concrete. Two trolley poles, about half

[1] Lecture delivered before the Tramway Congress at the Franco-British Exhibition, July 10, 1908.

a mile apart, were selected, and the distance between them chained and found to be 2,597 feet. If this distance were covered by simple rolling the counter would make 1,581 revolutions. The method of test was as follows: One observer was told off to take charge of the counter, a second to take the time and a third to call the start and the stop. The car was started up some distance behind the first pole, which it passed at full speed; at the moment of passing the third observer gave a signal; the time was taken and the counter inserted in the spur-wheel. The car covered the distance at constant speed without slowing down; on passing the second pole, at a given signal the time was taken and the counter withdrawn. The car was then brought to rest beyond the second pole and was changed over to the up track, when the same process was repeated in the reverse direction. The slight difference of level resulted in the up journey being made at a rather higher speed than the down journey. Two trips were made each way with the track very dry, and two trips each way after a heavy rainstorm, the track being then very wet, but not greasy. The results are given in the following table:

	Condition of Track.	Mean Counter Revolutions.	Skid in Counter Revolutions.	Skid in per Cent of Distance Covered.	Mean Speed Miles per Hour.
Down trip	Dry.	1,516	65	4.1	11.2
Down trip	Wet.	1,535	46	2.9	11.1
Up trip...	Dry.	1,522	59	3.7	14.4
Up trip...	Wet.	1,547	34	2.1	14.0

From these experiments it appeared that when a car travels along a tramway track the wheels skid upon the head of the rails in the same way as they do in the model.

It remained to be seen in what way the skidding, which had been shown to take place, could produce corrugation. For this purpose further experiments were made on the model. In order to get a definite amount of skid that should be independent of possible variations in the side pressure exerted, a metal fillet was inserted against one of the rails in such a way as to lift the keyed wheels off the rail and force them to roll on the outside of their flanges. The diameter of the outside of the flange is about nine per cent greater than that of the tread, and a pure roll on the flange would correspond with the distance AD on the rail, where BD is about nine per cent of AB, which represents three complete revolutions on the tread.

If the loose wheel is now fitted with a rigid coupler, the motion of the coupled wheel will be a roll and a skid, and of the keyed wheel a roll and a slip, the proportion of skid to slip depending upon the relative coefficients of friction, but the sum of the two always being equal to BD, or nine per cent of AB. With a total weight of forty-two pounds—that is, 10.5 pounds on each wheel, the coupled wheel skids about eight per cent. The skidding remains quite uniform and continuous as before.

If the coupler is removed from the notch and placed on one side of the stud, the loose wheel is at liberty to roll freely on the rail, and the coupler tends to draw away from the stud under the action of a definite force. This force can be made apparent if the rigid coupler is replaced by a spring coupler fixed in the notch. Whichever way the truck is pushed the spring is bent, indicating a tendency to twist the coupled wheel relatively to the axle. The angle through which the spring is bent represents the torsion required to overcome the adhesion between the tread of the wheel and the rail.

From these experiments it is evident that when the flange of a car wheel grinds against the rail in such a way as to cause skidding, the axle will be twisted until the torsion is sufficient to make the tread of the mate wheel skid on the rail, the elastic twist of the axle representing the bending of the spring in the model.

So far, however, the skidding is quite continuous, and there is no indication of any intermittent action such as could produce corrugation. But the experiments with the model have been carried out under conditions differing in one very important respect from those of actual practice: the rails have been quite clean. It remains to be seen what is the effect of making the rail surface rough, as it is in practice. For this purpose a little sand may be sprinkled over the surface of the rail. If the truck is now pushed along the track, an entirely new effect is produced: the coupled wheel, instead of moving uniformly as before, now advances with a series of jerks at regular intervals.

The action is as follows: When the torque on the spring has increased to a certain amount, the force of adhesion is overcome, and the wheel skids, turning meanwhile about its own axis, so that the whole force of the skid is concentrated over a limited area on the rail surface. In skidding the wheel grinds through the grit on the surface of the rail and comes into contact with clean metal; there is thus a large and sudden reduction in the coefficient of friction, and the wheel flies back under the influence of the spring through a considerable angle. The result is that the subsequent motion of the wheel upon the rail will be a pure roll while the spring is being again deflected. When the limit of adhesion is reached, the wheel again skids, and the process is repeated, the motion thus consisting of alternate rolling and skidding. The addition of the grit has made the skid intermittent, whereas formerly it was continuous. When the surface of the rail is clean, there is no sudden breaking down of the adhesion which is required to make the skid intermittent. This effect is not due to the increased torsion on the spring consequent on the increase in the coefficient of friction; for the same torsion can be obtained with a clean rail by increasing the weight, when the skid remains continuous.

So long as the rail is clean, the motion is thus continuous and uniform. In order to produce intermittent action it is essential that the rail surface should have been roughened by the application of some hard and gritty material. In tramway practice such material is furnished by dust, and especially by the sand which is put on the rails. According to my observations the presence of sharp grit on the rail surface is a prime factor in the production of corrugation. Numerous instances might be quoted where corrugations are worst in places where the rails are liable to be continually covered with sharp, gritty dust. Thus, in the case of the Brussels tramways, the worst corrugated section in the whole city is on the Boulevard de Waterloo, where the tram lines are flanked from end to end by a sand-covered avenue. This may also explain why the tram lines in one town—say, for example, Norwich—are badly corrugated, while at another — say, Coventry—where the track, the rails and the rolling stock are identical in character, there is little or no corrugation, the difference being due to the quantity of dry flint-dust that is blown over the Norwich tracks by the prevailing east winds.

The experiments on the model afford an explanation of the connection between check-cutting and corrugation. The flange of one of the two wheels on an axle grinds against the rail on a line of contact having a diameter greater than that of the tread, causing both wheels to skid. The skidding on the one side, where the flange is grinding, will be uniform, but on the other side, owing to the twist of the axle, the skidding will be intermittent, provided the rail surface be sufficiently rough, and the motion will be an alternate rolling and skidding. This explains why, as a rule, corrugations appear on one rail only: both wheels are skidding, but, owing to the twist of the axle, one skids uniformly and the other intermittently, the intermittent skidding taking place on the rail opposite to that where the flange is grinding. Observation shows that the rail opposite the corrugated rail is generally scored uniformly, though often with a slight wavy appearance which is caused by the sudden release of the twist on the axle affecting the motion of the non-corrugating wheel.

The distance apart of the marks on the rail, or the pitch of the corrugations, necessarily depends on the action above described. When the coefficient of adhesion, the weight on the wheel and the dimensions of the axle are fixed, the limiting amount of twist measured, say, in fractions of an inch at the rim of the wheel, is also fixed. Now the skid is a definite per cent of the distance traveled, say, x per cent, and when corrugation takes place the skid between any two marks is accumulated in the twist of the axle, hence x per cent of the pitch must equal the limiting twist on the axle. Thus if the skid is two per cent and the limiting twist 0.02 inch, the pitch would have to be one inch. It is necessary, therefore, to ascertain whether this relation holds good in practice.

With the car used in the Croydon tests the weight on each wheel was 4,370 pounds, the diameter of the axle three and three-quarters inches, and the distance between wheel hubs forty-eight inches. Taking the modulus of transverse elasticity for the axle at 14×10^6, and the coefficient of friction at 0.4*, the twist measured at the rim of a wheel thirty-one inches in diameter will be 0.073 inch. For a skid of three per cent the pitch of the corrugations would therefore have to be 2.4 inches. On the Croydon tramways the pitch of the corrugations on the straight varies from two and one-quarter inches to two and three-quarters inches.

During the process of corrugation the axle is subject to torsional vibration, and in order that the skidding may continue to take place intermittently the twisting force must be applied rhythmically with a time interval equal to the period of vibration of the axle. Hence the time occupied in covering the distance between two successive skids will be a constant quantity for any given wheels and axle. It follows, therefore, that the pitch of the corrugations will depend not only upon the skid, but also upon the speed of the car. Thus, if the mean speed is twelve miles an hour for corrugations having a pitch of two and one-half inches, when the speed is twenty-four miles an hour, the pitch would be five inches. This increase of pitch with speed has been noticed by many observers.

It would seem, then, that the pitch is determined, in the first place, by its relation to the per cent skid and the limiting twist on the axle, and in the second place by the speed, and that corrugation can not take place unless the two sets of conditions are to some extent in agreement. Thus in the case just quoted the skid at twenty-four miles an hour must be half that at twelve miles an hour; that is, if the skid is halved the speed must be doubled.

This may explain why on tramways in this country corrugations rarely appear unless accompanied by check-cutting on the opposite rail. Until such check-cutting takes place the side pressure is taken by the throat of the flange bearing against the head of the rail, the line of contact being only slightly below the tread of the wheel. Under these conditions the skid is small—not exceeding one or one and one-half per cent. Taking the relation of pitch to skid as calculated for the Croydon car, this amount of skid would correspond with corrugations having a pitch of from five inches to seven inches, involving a speed of from twenty-four to thirty-six miles an hour, or two to three times our normal speed. Hence the speeds on tramways in this country are too low to give corrugations except where the skid is large, as happens when there is check-cutting. Similar conditions obtain more or less on the Continent.

Where the speeds are higher, as on American tramways and on steam railways, corrugations may, and do, appear with the small per cent of skidding that is caused by the ordinary side pressure of the flange on the rail.

The side pressure of the flange on the rail that is necessary for the production of corrugations is caused, on the straight, by irregularities of gauge and level, which make the car lunge from side to side and bear over against one rail or the other. This accounts for the irregular distribution of corrugations along the track, first on one side, then on the other, in long or short stretches, with smooth parts in between. The tendency of a car to lunge from side to side in the manner described neutralizes the tendency of the car to ride down on the lower side on a double track, in spite of the usual camber, and corrugations are found quite as frequently on the inside as on the outside rail on a double track on the straight. The irregularities of gauge and level, due in the first instance to faulty construction, are augmented by the wear and vibration to which the track is subjected. This is one reason why corrugations generally take time to develop.

On a curve there is always a definite force, due to centrifugal action, tending to press the flanges outward. If the curve is of large radius the speed will be practically the same as on the straight, and the conditions under which corrugations may be produced will be similar, except that the pressure is constant and always in one direction. When flanges and rails are new the pressure is between the outer flange and the outer rail, but the skidding thus caused is small, and not enough to produce corrugations at ordinary speeds. After sufficient wear has taken place to bring the inside flange against the check of the inner rail, corrugation will begin on the outer rail. For this reason, on any tramway system, corrugation will generally first begin on large radius curves, corrugations appearing on the outer rail accompanied by cutting of the check of the inner rail.

The difference of length between the inner and the outer rail on a curve gives rise to a skidding or slipping quite apart from that due to the grinding of the flange on the rail. With curves of large radius this difference is small, and does not greatly affect the conditions of corrugation. With curves of small radius the difference produces a skidding or slipping which is large compared with that produced by flange grinding, and the conditions of corrugation become very complex. Speaking generally, however, it may be said that the speeds on small-radius curves are, as a rule, too low to admit of corrugations being formed.

The pitch of the corrugations on a curve is generally less than on the straight. Thus in the case of a car which produces corrugations on the straight having a pitch of 2.4 inches with three per cent skid, on a curve of 500-foot radius

*The most complete tests made to determine the coefficient of adhesion for a wheel on a rail under varying conditions are those made by Captain Galton, and published in the Proceedings of the Institution of Mechanical Engineers, 1878-9. The results there recorded indicate that the limiting or static coefficient of adhesion, immediately previous to skidding, exceeded 0.38 for a clean dry rail, and rose still higher on the application of sand. The value 0.4 is here taken as the limiting coefficient of adhesion.

the skid on the outer rail due to the difference in the length of the inner and outer rails will be about 0.9 per cent, making a total of 3.9 per cent. Now the pitch is inversely proportional to the per cent skid, so that the pitch of the corrugations on the curve should be about 1.9 inches. Observation shows that the pitch on curves is reduced about in this proportion.

The appearance of corrugations on the grooveless girder-rail used in Philadelphia and other American cities presents some interesting features in connection with what has been said as to side-flange pressure. A full report on this subject was presented by H. B. Nichols, engineer to the Philadelphia Rapid Transit Company, at the 1907 convention of the American Street Railway Engineering Association. (See Tramways and Light Railways Association circular for April, 1907.) A section of the rail and tire used in Philadelphia is reproduced in Fig. 3. The rail shown is a ninety-three-pound girder-rail, eight and three-quarters inches deep with a three-eighths-inch web. Careful observation showed that when the normal traffic was passing over this rail at a point on the straight where corrugations had appeared, the head of the rail was forced outward, due to a bending of the web, by as much as three-thirty-seconds inch. The web was then stiffened by the addition of fishplates, after which the corrugations disappeared. Subsequently this rail was replaced by another rail weighing 137 pounds, with a one-half-inch web, after which corrugations appeared only in a few places. Finally this rail was replaced by a rail weighing 141 pounds, with a nine-sixteenths-inch web, after which there was no trouble from corrugations.

It has been suggested that the corrugations in this case were due to vibrations in the rail, which were stopped by the stiffening of the web; but I would submit the following as a more probable explanation. A side deflection of three-thirty-seconds inch corresponds to vertical depression of 0.03 inch at the outside of the tread of the wheel—that is to say, the side pressure caused by the lunging of the car lifted the wheel off its tread, and threw almost the whole weight on the throat of the flange, causing the wheel to ride on a line of contact about one-quarter inch below the head of the rail —that is, on a diameter about one and one-half per cent greater than that of the tread—thus producing corrugations in accordance with the principles already stated. A simple calculation will show that when the web has been thickened to nine-sixteenths inch the lift off the tread for an equal side pressure has been reduced to 0.009 inch, and the tendency of the wheel to ride on a larger diameter than the tread has been practically eliminated.

Although corrugations are, in my opinion, generally caused by the grinding of the flange on the rail, this is not the only way in which they may be produced. A similar action may be set up if for any reason the wheel should be forced to run on its flange. This often happens at points and crossings, the tread of the rail being lifted clear off the rail-head, when corrugations may frequently be observed on the opposite rail. The same thing happens when the rail has been badly worn and the flange actually touches the bottom of the groove.

The most common example of flange riding, however, is found where the groove is allowed to get full of dirt. I have seen places where the groove has been packed with a mixture of dirt, wood-pavement scrapings, paper, etc., so hard as to resist any attempts to move it with a metal-tipped stick. The flange runs on this packing, and if the other groove does not happen to be packed so full, corrugations will appear on the opposite rail. In the course of a few days the first groove may get cleaned out and the other groove may get packed, when the conditions will be reversed, and corrugations will then appear on the previously uncorrugated rail.

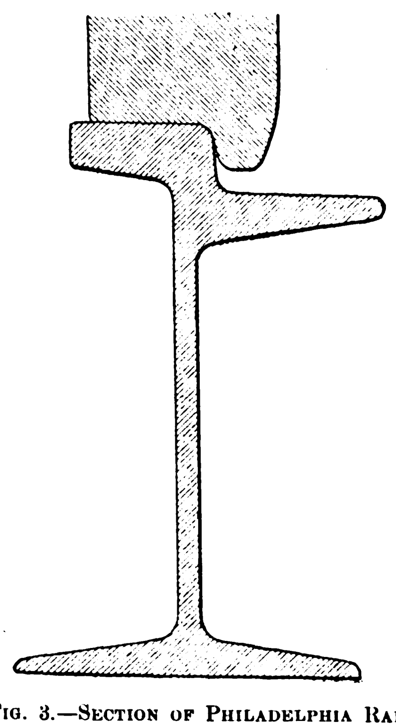

FIG. 3.—SECTION OF PHILADELPHIA RAIL.

In this way both rails become corrugated. Flange riding on a packed groove is responsible for some of the most perplexing vagaries of corrugation. The hardness of the packing depends very largely on the condition of the weather. Corrugations may be very pronounced in a certain place owing to a packed groove. A few days' rain will soften the packing and remove the cause of the corrugations, which will then get worn down and disappear, only to reappear again, perhaps on the other filled.

The corrugations which have appeared on certain steam railways in India illustrate the conclusions arrived at above as to the conditions under which oorrugations are produced. For more than ten years past corrugations have been noticed on some Indian railways, especially on the Eastern Bengal State Railway, a full account of which may be found in a paper written by G. Moyle, published in the official circular of the Tramways and Light Railways Association for June, 1906. Investigations of an exhaustive character were carried out with a view to ascertaining the cause of these corrugations. The following definite conclusions were arrived at: (1) The track on which the corrugations appeared was invariably found to be boxed with burnt clay or brick. (2) Corrugations were hardly ever found with stone boxing and never with earth boxing. (3) When the brick boxing was replaced by earth or stone boxing the corrugations disappeared. (4) To get this result it was necessary to change the boxing only, and not to remove the brick ballast packing under the sleepers. (5) Corrugated rails removed and replaced on an earth-boxed section would wear smooth, while smooth rails taken up and set down on a brick-boxed section would become corrugated.

A careful study of Mr. Moyle's paper, and the conclusions there stated, convinced me that the corrugations were in some way caused by the gritty dust that would work up from the brick boxing and be scattered over the surface of the rail by the air suction of passing trains. A possible objection to this view might be found in the fact that corrugations had appeared on open-girder bridges, where, of course, there was no brick boxing. But the objection might turn out to be a confirmation if it could be shown that the approaches to these bridges were brick-boxed, for in that case the brick dust could be carried on to the bridge by the suction of the train. Upon inquiry I was informed that investigation showed that corrugation only developed on open-girder bridges the approaches to which were brick-boxed, thus confirming the suspicion that the corrugations were in some way caused by the dust from the brick boxing.

It remained to be ascertained in what way this dust could be essential to the production of corrugations. The subsequent experiments on the model, already described, showing how intermittent skidding is brought about by covering the rail with a gritty powder, seemed to afford the required solution. Through the kindness of Sir Alexander Rendel and F. E. Robertson I was supplied with a sample of the brick boxing taken from a section of the Eastern Bengal State Railway, where corrugations are very pronounced. Some of the brick was crushed, making an exceedingly sharp and gritty powder. The model was arranged as before with a spring coupler in the loose wheel. So long as the rail remained clean the skidding was quite uniform as the truck was pushed along the track. When a little of the brick powder was scattered over the rail the skidding immediately became intermittent, indicating clearly the part played by the brick boxing in the formation of corrugations.

The investigations outlined above appear to show that the following conditions are necessary for the formation of corrugations on grooved rails:

(1) As regards the track:

(*a*) Irregularities in gauge or level,

or

(*b*) Curvature,

or

(*c*) A packed groove.

(2) As regards the rails:

(*d*) Surface rough with sand or gritty dust.

(3) As regards the rolling stock:

(*e*) Wheels with check-cutting flanges.

(4) As regards traffic:

(*f*) A critical speed.

Corrugations can not be formed unless conditions (1), (2), (3) and (4) are all present at the same time—that is, peculiar conditions must exist simultaneously in the track, the rails, the rolling stock and the speed, and the absence of any one of these conditions will prevent corrugations being formed. These considerations suggest the lines on which it may be possible to avoid the formation of corrugations. My object this morning, however, is simply to put before you the conditions under which corrugations are produced, in the belief that a correct diagnosis of the disease is the first step to be taken toward providing a remedy.

Legality of Public Service Commission Questioned.

An order has been issued on Mayor McClellan, Comptroller Metz and the Public Service Commission directing them all to appear in court. This order, which has been promulgated by Adolph Gutner through an attorney, is a notice that a motion will be made before Justice Bischoff in Part II of the Supreme Court on August 31 why an injunction should not be granted pending the determination of the suit. The injunction is sought to prevent the further payment from the city treasury of the expenses of the Public Service Commission of the first district.

The plaintiff and his attorney, Mr. Leary, propose to put Governor Hughes's Public Service Commissions to the test of a judicial scrutiny, and Mr. Leary thinks he has an unanswerable argument against the constitutionality of one of the chief sections of Chapter 429, Laws of 1907, which act establishes the Public Service Commissions and prescribes their powers and duties and provides, through them, for the regulation and control of the public service corporations. He attacks the provision in the act that makes an appropriation for the expenses and salaries.

Lawyer Leary's principal claim against the constitutionality of the act providing for the two commissions is that it makes obligatory upon the city the payment of the expenses of a purely state and not a local official body. Granting that the two commissions are composed of state officers he asserts that the imposition upon the city of New York of several hundred thousand dollars each year of expenses for one of them is clearly unconstitutional; that the city can incur no indebtedness except for city purposes. Lawyer Leary proposes to get the courts to stop Comptroller Metz from paying any more of the expense bills of the commissioners who have to do entirely with the first district. His attack upon the second district commission is based upon other grounds.

In Section 14 of Chapter 429, Laws of 1907, relating to the payment of the commissions' salaries and expenses, Lawyer Leary points out that the salaries of the commissioners, the counsel and secretary shall be audited and allowed by the state comptroller and paid monthly by the state treasurer. The commissioners were appointed by Governor Hughes and they have control over state corporations; the city officials have no power over them or their expenses and the Appellate Division of the Supreme Court, another state institution, orders the bills paid. All this, Lawyer Leary insists, makes the commission a state board.

In his complaint the plaintiff asserts that the board of estimate has appropriated large sums of money belonging to the city on the requisition of the commission, and that the payment of this money is an illegal act on the part of the city officials. He asks that the city chamberlain and comptroller be stopped from making the payments, as the plaintiff "is advised and he is informed, and believes that the said act, Chapter 429, Laws of 1907, is wholly unconstitutional and void; and in particular the aforesaid Section 14 of said act, in so far as it attempts to impose upon the city of New York the payment of the expenses of said Public Service Commissions."

Fatal Shock from Portable Electric Lamp.

At Pinxton, England, an inquest was held on the body of William E. Phillips, a young man who was killed in the locomotive shed adjoining No. 1 pit of the Pinxton Collieries, Limited, several weeks ago, it is alleged by shock from a portable electric lamp. The evidence of Joseph Surgey, a locomotive driver, was to the effect that Surgey and the deceased were working together. Surgey left the shed, and in his absence the deceased picked up a portable lamp which was attached to an electric cable. He cried out, and when the witness went to his assistance he was found to be dead. Fred Smith, of the Langton Colliery, the electrician for the owners, said he found the porcelain inside the lamp broken, and the lamp partly unscrewed.

Cleveland Municipal Traction Makes Better Showing.

According to figures given out by the Municipal Traction Company, Cleveland, three-cent fares made a profit of $19,686 for the company during the month of July. This is the first statement which has not shown a deficit. For May, the first month the street railways were operated at three-cent fares, a loss of $54,916 was reported. During that month the motormen and conductors were on a strike. For June the loss was given at $23,829. The gross earnings for July were $437,174.

A New Type of Switchboard for the United States Reclamation Service—Salt River Project.

The Salt River project of the United States Reclamation Service is more or less familiar to a great many individuals on account of the wide advertising it has received, due to the immense size of the dam and storage basin, the latter being the largest artificial reservoir in the world; and also because the large town of Roosevelt will be wiped out of existence when the reservoir is filled. About 200,000 acres of arid land near Phœnix, Ariz., is to be irrigated by a canal system fed from the main reservoir, and it is intended to irrigate an additional 40,000 acres by underground waters, made available by the installation of pumping stations at suitable points. Two important features of the Salt River project are a 6,000-kilowatt hydroelectric power station and a 45,000-volt transmission system.
